APPLICATIONS are invited by St. John's College, Cambridge, for the Kenneth Craik Research Award, which is available for the assistance of persons engaged in postgraduate research, preferably in physiological psychology. The value of the Award will be £450 a year. Applications should be sent to the Master, St. John's College, Cambridge, so as to reach him not later than April 1, 1961.

A NEW colour magazine, *Knowledge*, has appeared. It is intended, by an easy appeal, to give children a glimpse of "the strange variety of things that the world has to show", as the editorial states. There is a South American edition too, and similar editions will be forthcoming from other countries; a cultural exchange of articles is planned. The magazine costs 2*s*. and appears every Monday (Purnell and Sons, Ltd., 37 Hertford Street, London, W.1).

THE Royal Society has available for loan to film societies, educational institutions, schools, etc., a 16-mm. sound film in colour which runs for about 40 min. entitled "South from Chiloé" at a nominal service charge of two guineas per showing. This film tells the story of the Society's expedition to Southern Chile during the period October 1958–February 1959 which went to study the flora and fauna of this little-known region of the world. Requests for hire should be addressed to the Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1.

THE Society of Leather Trades' Chemists is organizing a symposium on "The Technology of Drying Fibrous Materials with Particular Reference to Leather" during March 23–24. The symposium will be held in the Physical Chemistry Department, University of Cambridge. Further information can be obtained from G. H. W. Humphreys, 3 The Grove, Radlett, Herts.

A SYMPOSIUM on "Microchemical Techniques" is being organized by the Metropolitan Microchemical Society under the sponsorship of the International Union of Pure and Applied Chemistry. The symposium will be held at the Pennsylvania State University during August 13–18. Further information can be obtained from Mr. Howard J. Francis, jun., c/o Pennsalt Chemicals Corporation, P.O. 4388, Philadelphia 18, Pennsylvania.

NEW RESEARCH LABORATORIES OF HILGER AND WATTS, LTD.

SINCE the Second World War, the idea conjured up by the expression 'scientific instrument' has changed. It is well known that electronics has invaded every field of measurement, including the optical field, but it is less realized that instruments have tended to become larger. They have done so not only because of the addition of electronic units but also because this in turn has made possible complexities that would previously not have been considered.

To take one example, the quality of steel during the War was controlled by using the large quartz spectrograph, the photographic plates exposed in which carried the spectra of some twenty samples together with calibration spectra. The blackness of the lines at the appropriate places was measured with a microphotometer, reading from a galvanometer scale. Nowadays, when a charge of 70 tons of steel may be prepared and poured in 12 min., the foreman must have the analysis of a sample in as few minutes as possible if he is to have time to take any necessary action to rectify the charge. The automatic spectrograph or 'polychromator' takes up three or four times the space of the equipment previously used, but it provides an analysis of as many as thirty elements in about 3 min. in a typical case. To determine the carbon, phosphorus and sulphur in a sample, instruments are made that use the vacuum ultra-violet region of the spectrum as well as the air-penetrating ultra-violet region.

This trend, as well as the rise in numbers of instruments required, has induced Messrs. Hilger and Watts, Ltd., to build a new research laboratory at Camden Town, London, N.W.1, as an extension of their headquarters building there. Since the comprehensive damage to the factory caused by a flying bomb in 1944, research on instruments for analytical and kindred purposes has been carried out in rooms spread over the factory and adjacent outbuildings. (This does not apply to the research on surveying, photogrammetric and engineers' measuring instruments being done at the firm's Camberwell factory.)

The use of the new building was inaugurated by Sir George Thomson on December 15. The ceremony took the form of visiting the laboratories, in which normal work was in progress, and a luncheon attended by some 150 guests. The guests were drawn from among university physical and chemical departments, medical and government laboratories, and the research laboratories of industry.

Sir George was introduced by the chairman of the Company, Mr. G. A. Whipple, who is the present master of the Company of Scientific Instrument Makers. Mr. Whipple referred to the growth of the firm, which now has more than 2,000 employees, an associated company in the United States, and branch offices in Canada and Western Germany. He thanked the architect (Mr. J. Francis Smith), the builders (Messrs. Mullen and Lumsden), and the quantity surveyor (Mr. D. T. C. Thompson).

Sir George then proposed the toast of the Company and the new laboratories. He spoke of the 'pure' research worker's debt to industry, in that the needs of industry for large and complex instruments, which had to be reliable, encouraged the scientific instrument firms, which in turn could provide better instruments for pure research. Hilger and Watts was such a firm: "Twyman proved to industry the value of spectroscopic analysis. The demand so created made expansion possible, and its latest stage we are inaugurating to-day. From this, we benefit by the increased scale of the firm and by the great improvement this has made possible in design, which has given this great firm the enormous prestige it now holds throughout the world and which we are happy to be here to-day to celebrate".

Dr. A. C. Menzies, the firm's director of research, said in his reply that he had been concerned in his

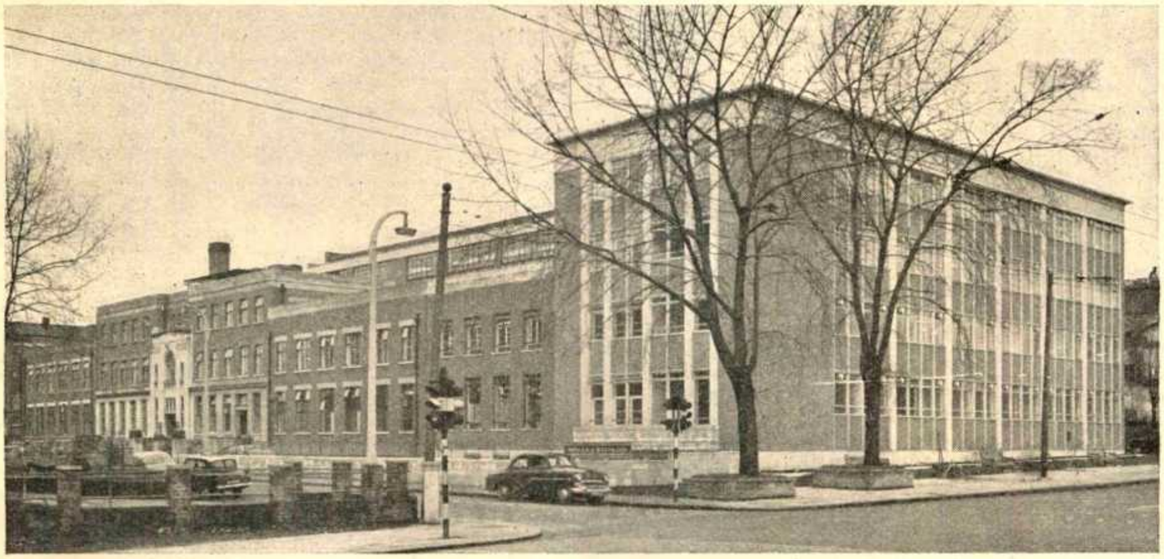

Fig. 1. New Research Laboratory of Hilger and Watts, Ltd.

life with the building of three laboratories. However, it was only with the third of them, this new laboratory at Camden Town, that he had had the pleasure of contributing little but the expression of his requirements. This was the result of having good colleagues. He had worked with Sir George Thomson during the War, and it was at Sir George's instance that he had come to Hilger and Watts to succeed Mr. Frank Twyman. Sir George had added with a smile that the job was an easy one, so Dr. Menzies had frequently overcome difficulties since then by reminding himself that they could not exist. When he started with the firm, he turned one of the smallest rooms in an outside building into a dark room; "it had the advantage that water was laid on already". Such conditions made him resolve to work for a satisfactory, attractive place where his colleagues could work comfortably and effectively. Now they had it.

After the luncheon, the guests toured the laboratories and saw research being undertaken into spectroscopic analysis by emission, X-ray diffraction and X-ray fluorescence; infra-red absorption; optical design; absorption spectroscopy; optical instruments for the control of chemical processes; electron-spin resonance spectrometry; and generators for arcs and sparks. N. J. GOODMAN

SCIENTIFIC RESEARCH IN AUSTRALIA

THE twelfth annual report of the Commonwealth (of Australia) Scientific and Industrial Research Organization, covering the year ended June 30, 1960, departs considerably from the form of previous years*. To facilitate its presentation to Parliament early in the 1960 Budget sitting, the chapters describing detailed technical matters characterizing previous reports have been replaced by a brief account of the more important developments during the year, and the details are to be published separately as a research review. The bulk of the present report consists of lists of published papers, and the membership of the Advisory Council, State Committees and staff and finance.

Of the expenditure of £9,489,741, £8,862,160 was on normal research activities and £144,600 on grants to outside bodies. Among new arrangements with the universities are noted support of an investigation by the Department of Zoology, University of Melbourne, into the effects of chromosomal inversion on viability of grasshoppers; collaboration with the University of New South Wales in an investigation of tritium-labelling techniques; continuation of research at the Australian National University into aggregation and denaturation of protein; and an extended loan to the Electrical Engineering Department, University of Tasmania, of the differential analyser developed by the Mathematical Instruments Section. Construction of the giant radiotelescope at Parkes, New South Wales, for the Division of Radiophysics is expected to be complete early in 1961.

Among the more important developments of the year noted in the chapter "Progress in Research" are the solution of serious problems preventing the development by irrigation of large areas of potentially fertile but intractable soils in the Riverina by using low concentrations of gypsum in the irrigation water to make the surface clays permeable. A study of the characteristics of coats of cattle in the tropics showed that gain in weight can be predicted much more accurately from the type of coat than from actual records of past gain in weight. A new process by which cheese is matured in a plastic wrapping has been adapted for Australian conditions, and a new kind of anti-fungal compound, 'Pisatin', has been isolated from peas. A strain of cocksfoot grass, introduced from Brignolles in France, has proved outstandingly productive as a component of winter pastures near Canberra and has persisted well under heavy stocking. Up to 90 per cent control of rabbits has been achieved with sodium fluoroacetate using a suitable bait; but its effective use depends on intelligent application of accurate knowledge of feeding habits and behaviour of the rabbit. Striking increases in beef production have been obtained in grazing trials with a grass-legume mixture in native spear grass country near Gladstone, and further evidence has been obtained of the primary importance of nutritional factors in determining the mortality among new-born lambs. The compounds causing certain off-flavours in butter have been identified, and most of the conditions under which these flavours develop have been recognized. Research at Crookwell has shown that sulphur is an essential constituent of the soil organic matter, and that lack of sulphur often limits the rate of build-up of soil fertility under improved pastures.

The first commercial plant for the manufacture of fully mechanized Cheddar cheese has been installed and successfully operated, and a field experiment in North Queensland suggests that control of the cattle tick can be greatly improved both by pasture spelling and strategic dipping. Equipment has been designed to overcome the difficulty of measuring the temperature of biscuits in a long conveyor-type oven due to the very limited access to the interior of the oven, and the method for producing washable non-iron effects in wool fabrics has reached commercial application. Two new statistical techniques have been developed for accurate spatial prediction of rainfall.

Polyethylene box liners have been used to increase significantly the storage life of four main varieties of apples. A new pre-steaming procedure has been developed which is greatly improving the drying of refractory timbers with a saving of 20 per cent in the time of drying with some species. It has now been found that sugar-cane wax as it occurs on the cane consists chiefly of polymerized long-chain aldehydes, with lesser amounts of long-chain alcohols. A study has also been made of the waxes coating the tubercule and diphtheria bacteria.

Investigations of the hardening of brass have proved that alpha brass is 'ordered' after slow-cooling treatments, and that the degree of order can be considerably increased by isothermal annealing at low temperatures. X-ray methods have been further developed for the determination of the structures of large molecules, by applying a high-power X-ray generator and by collecting intensity data at low temperatures. In extensive tests at Umberumberka (Broken Hill) and at Lake Corella reductions of as much as 50 per cent of the normal evaporation have been obtained in still conditions by dusting with solid hexadecanol, but when the wind velocity exceeds 5 m.p.h. the saving is very much less. The first model of the 'Evaporotron', an instrument designed to yield direct readings of evaporation from natural sources on the eddy-flux principle, has been completed. Fundamental study of the physics of wool has established the existence of a transition temperature above which irreversible change occurs if the wool fibre is strained, and also that fibres of animal tendon have a transition temperature only slightly above normal blood temperature. Investigations of the retarding of non-enzymic browning of stored food by addition of sulphur dioxide or bisulphite indicate that the bisulphites may act through oxidation of the carbonyl compounds found in the aldose-amine reactions preceding browning.

STRONTIUM-90 IN HUMAN DIET IN THE UNITED KINGDOM, 1959

A REPORT by the Agricultural Research Council contains the results for the second year of the survey of strontium-90 in human diet in the United Kingdom which was initiated by its Radiobiological Laboratory in 1958*. Two types of investigation are described: a country-wide survey, which enables the mean ratio of strontium-90 to calcium in the average diet of the population to be assessed, and local studies in areas where the quantities of strontium-90 in the diet are likely to exceed the average.

The general organization of the country-wide survey was similar to that in 1958, though some additional foods were examined. The major effort was devoted to milk; bulk samples were prepared for analysis from milk collected twice each month from some 200 depots which handled more than 40 per cent of Britain's total production. Potatoes, leaf vegetables, flour, cheese, eggs, proprietary cereal-based infant foods and tea were also examined. It has already been reported that the quantity of strontium-90 in milk rose appreciably in the early part of 1959 with the result that the mean value for the twelve months ending in the middle of the year was 40 per cent greater than it had been six months earlier. Afterwards, however, the level of strontium-90 in milk decreased and, in the latter part of the year, it was similar to those observed in 1958; thus, the mean value for the preceding twelve months changed little between June and December. The country-wide mean values at the end of June and December 1959 were 11·7 and 12·2 μμc./l. (9·6 and 9·8 μμc./gm. calcium), respectively.

It is estimated that the mean ratio of strontium-90 to calcium in the average diet of the whole population in the United Kingdom during 1959 was 9·0 μμc./gm. and that it did not exceed 15 μμc./gm. in the diet of any large section of the population. Because of the relatively high levels of contamination early in the year, these values are about 50 per cent higher than those estimated for 1958. The estimated level in the diet of the population as a whole, however, represents less than one-twentieth of the maximum permissible level recommended by the Medical Research Council.

During the year, investigations were intensified to identify localized areas where the combination of high rainfall and agricultural factors could lead to abnormally high levels of strontium-90 in human food. Thirteen individual farms or groups of small adjacent farms were examined in wet upland areas in England, Wales, Scotland and Northern Ireland. All these areas are small, and only a fraction of the food consumed in them is produced locally. The results of these studies, however, enable conclusions to be reached as to the hypothetical maximum levels of strontium-90 which could occur in the diet of any individual. If it is assumed that an individual could consume the most highly contaminated foods of different types which have been found in these investigations (and these were, in fact, produced in widely separated parts of the country), the ratio of strontium-90 to calcium in the total diet would be 80 μμc./gm. This value, which is one-tenth of the maximum permissible level recommended by the Medical Research Council for individuals, is in fact considerably in excess of the likely levels in the diet of any one person. Moreover, it is less than one-third of the maximum permissible level for the whole population.

Milk continues to be the component of diet which contributes the largest quantities of strontium-90. The ratio of strontium-90 to calcium in milk is, however, similar to, or less than, that in many other foods. Since the concentration of strontium-90 in newly formed human bone depends on the ratio of strontium-90 to calcium, rather than on the absolute quantity of strontium-90 in the total diet, milk should not be regarded as giving rise to any special hazard.

Variations in the composition of diet usually have only small effects on the mean ratio of strontium-90 to calcium in the total daily intake. The only substitution in a normal diet which is likely to have a significant effect is that of wholemeal bread for white bread. The calculations in this report for the average mixed diet are for that containing white bread. The substitution of wholemeal bread which contains a higher quantity of strontium-90, and does not generally contain added calcium of mineral origin, would not, however, increase the ratio of strontium-90 to calcium in the average mixed diet by more than 6 μμc./gm. This increase is less than one-fortieth of the maximum permissible level for the general population.

Because climatic factors can exert considerable effects on the quantities of strontium-90 and of calcium which are absorbed by plants, and hence on the levels in human diet, it is not possible to make quantitative predictions as to the situation in the immediate future. There is, however, considerable evidence that strontium-90 which has hitherto been released into the atmosphere has already exerted its major effect; decreasing levels in human diet may therefore be expected in the future.

RESEARCH IN PARASITOLOGY

THE autumn meeting of the Parasitology Group of the Institute of Biology was held in the Zoology Department of Birkbeck College, London, on October 28. The meeting was very well attended and was devoted to five papers under the general title "Recent Advances in Fields of Parasitological Research". A short discussion followed each paper.

During the morning session the chair was taken by Dr. Ann Bishop. The first paper, given by Mr. Bernard Weitz (Lister Institute, Elstree), was on "Trypanosomiasis". Mr. Weitz pointed out that eradication of the disease depends on the control of the vector or the elimination of the reservoir hosts. *Glossina* can be controlled by bush clearing and, more recently, by the critical use of insecticides. Eradication of the insect by the sterilization of males by γ-irradiation is not practicable at present. Destruction of game removes the source of food of the vector and the parasite reservoir simultaneously. Consideration of the feeding habits of *Glossina* might permit the partial destruction of game, resulting in starvation of the fly. Animals which are frequently bitten by *Glossina* are usually tolerant to artificial infection, and, conversely, those which are infrequently fed on by the insect develop a parasitæmia and die more rapidly. On the other hand, it is difficult to understand how animals which are seldom or never bitten by tsetse become frequently infected unless by some other method of transmission. It is not clear whence the infection in the fly is derived. Immunity of animals can be assessed by a number of tests, but the specificity or sensitivity of the available serological techniques has led to confusing conclusions. The respiration test was recently used to measure the immune response of apparently resistant breeds of cattle. Recent attempts to investigate the antigenic pattern of trypanosomes showed that soluble antigens, released in the bloodstream of infected laboratory animals, influence infection. Laboratory animals immunized with these soluble antigens are protected against infection. Other antigens are released on mechanical disintegration of the trypanosomes. The occurrence of these antigens has been confirmed in the natural disease. Drugs are an important means of control of the disease but cannot be considered as a permanent measure. The local eradication of the disease must depend on concerted action by the use of all available methods of control.

This was followed by a paper by Dr. B. A. Newton (Department of Biochemistry, Cambridge) on "The Mode of Action of Quaternary Ammonium Trypanocides". The early work of Lock (1950) and Ormerod (1951, 1952) on the mode of action of ethidium bromide and 'Antrycide' indicated that these compounds differed markedly from the older type of trypanocidal drug (for example, trivalent phenyl arsenoxides, stilbamidine and acriflavine). Cytochemical studies led Ormerod to suggest that both compounds act in a similar manner by combining with, and inactivating, cytoplasmic ribonucleoprotein. Stimulated by these observations, work has been carried out on the action of ethidium bromide and 'Antrycide' on the trypanosomid flagellate, *Strigomonas oncopelti*, growing in a chemically defined medium. It has been found that these two drugs differ in their effect on the growth of *Strigomonas*; ethidium inhibits growth after about one generation, whereas 'Antrycide' changes the pattern of growth from a logarithmic form to a linear form. Examination of drug-treated cells has revealed an abnormal ratio of ribonucleic acid to deoxyribonucleic acid following ethidium treatment; no such change was observed after 'Antrycide' treatment. A more detailed investigation of the effects of these two compounds has shown that ethidium rapidly inhibits the synthesis of deoxyribonucleic acid, but permits the synthesis of ribonucleic acid and protein to continue for a limited time; antrycide, on the other hand, specifically inhibits the incorporation of purines into nucleic acid, but does not inhibit the net synthesis of nucleic acid so long as the organisms are able to synthesize purines. This action of 'Antrycide' is associated with the pyrimidine portion of the molecule. Examination of an 'Antrycide'-resistant strain of *S. oncopelti*, which has been developed *in vitro*, suggests that resistance is not associated with a change in cell permeability, or with a change in the affinity of cytoplasmic nucleoprotein for the drug. The possible nature of resistance was briefly discussed.

The afternoon session, under the chairmanship of Dr. E. L. Taylor, opened with a paper by Dr. C. Ellenby (Department of Zoology, King's College, Newcastle) on "Plant Nematology". Dr. Ellenby confined his remarks almost entirely to the cyst-forming eelworms of the genera *Heterodera* and *Meloidogyne* and considered aspects related to secretions, not only from the plants but also from the nematodes themselves, and their influence on nematodes and plants respectively. Among the points mentioned were the secretions from bacteria and various host and non-host plants, the suppressant effect on eelworm populations of diffusates from the roots of marigold (*Tagetes*), hatching factors (including his own work and that of Schreiber), and the influence of nematodes on plant growth, trap formation in fungi and gall formation in the host plants. Gall formation and specificity were then outlined and this led to a consideration of 'resistance'. Finally, sex ratio and sex determination were discussed in the light of recent work on the possibility of sex reversal in a species of *Meloidogyne*.

The second paper was given by Dr. C. A. Wright (British Museum, Natural History) under the title "Malacology". Development of recent work on the identity of intermediate hosts of trematodes of medical and veterinary importance has shown the existence of a greater degree of host restriction at the molluscan stage of the life-cyle than was formerly accepted. This has led to the idea of a parallel evolution between trematode species and their molluscan hosts, and has emphasized the importance of infra-specific taxonomy, often at the population-level, in the study of the hosts. Originally the taxonomy of molluscs was based on shell characters alone, characters which are now known to be very variable, and the result was the naming of large numbers of redundant 'species'. Later workers used the radulæ of gastropods as a further aid to identification, but, here again, insufficient attention was given to individual variations. The study of anatomical characters, particularly of the genital system, has been developed relatively recently and, in many cases, has provided useful taxonomic information. However, the plasticity of muscular structures and the effects on them of different methods of fixation, and also differences due to the maturity of the animal, necessitate a very careful interpretation of these anatomical data. Work is at present directed towards attempts to supplement the morphological criteria for species discrimination by biochemical characters, and the application of techniques such as paper chromatography of mucus, electrophoresis of blood proteins and systematic serology based on tissue extracts is beginning to provide a sounder basis for the systematics of the molluscan intermediate hosts of trematodes.

The last paper of the meeting was by Dr. C. Horton-Smith (Houghton Poultry Research Station) and was on "Poultry Parasites and their Control". A short review of the Coccidia of poultry introduced the main theme of the paper which was a discussion of the chemotherapy of coccidiosis, and the problems of developing drug resistance in *Eimeria tenella*; this occurs when the organism is exposed, over extended periods, to low and therapeutic concentrations of anti-coccidial compounds. The reactions of different strains of the same species, as well as the differences in species response to the same drug, were considered. The mode of action of anti-coccidial drugs, including the potentiation of sulphonamides by pyrimethamine, and the effect of anti-coccidials on developing immunity were also discussed. The selective action of certain sulphonamides on schizogony and, in particular, the second generation, associates this stage with the major role in the stimulation of resistance to *E. tenella*. This is amplified by the results of recent work. Finally, the mechanism of response to *E. tenella* was considered. Precipitating antibodies have been demonstrated as a result of the oral administration of oocysts, but the significance of these precipitins is, as yet, unknown.

The proceedings of this meeting will not be published in full. SHEILA WILLMOTT

NATURAL RUBBER RESEARCH

THE Natural Rubber Research Conference, held in Kuala Lumpur during September 26–October 1, was sponsored by the Rubber Research Institute of Malaya and the Government of the Federation of Malaya. More than 280 scientists from 24 countries and all five continents attended, and considered some 76 research papers, making this by far the largest gathering ever to discuss research on the production and utilization of natural rubber.

As in the case of other industries based on natural products, the range of research sponsored by the natural rubber industry is exceedingly wide, and the papers were representative of many scientific disciplines. Thus, the topics discussed ranged from the role of trace elements in the nutrition of the *Hevea* tree, to biochemical and biophysical investigations of latex, and to the design of rubber components in structural engineering.

During the week, the conference heard lectures from three distinguished guests: Prof. G. E. Blackman, Prof. James Bonner and Prof. G. Gee.

Biological Studies of the Rubber Tree

Prof. Blackman spoke on "The Stimulation of Latex-Flow by Plant-growth Regulators". In tracing the history of the development of successful yield stimulant mixtures, which increase the flow of latex after tapping, he showed how this had been dependent on fundamental research into the activities of plant-growth substances. It had been estimated that several million pounds worth of additional rubber had been produced in Malaya during the past four years by the use of these stimulants. Prof. Blackman made it clear that there was still much to be learnt about the exact mechanism of the yield stimulation process; but, as other papers presented to the conference indicated, this is the subject of active work. Other authors discussed such matters as the formulation of stimulant mixtures, their application to the tree and factors influencing the response obtained. A new aspect of yield stimulation was provided by a report that yield increases may also be obtained by the use of antibiotic treatments.

Of no less importance than yield stimulation is the development of intensive tapping methods which permit the maximum exploitation of older trees. Experiments are now in progress to determine the optimum combinations of tapping systems and yield stimulation techniques to give the highest possible yield throughout the life of the rubber tree.

Several papers considered various aspects of the breeding and selection work which has always found a prominent place in the programmes of rubber research organizations. The newer varieties now being planted are capable of giving at least four times the yield of the unselected material used in the early years of the century. It is believed, however, that all the high-yielding Eastern varieties are susceptible to the South American leaf blight disease caused by the fungus *Dothidella ulei*. A number of speakers directed attention to the potential threat of this disease to the rubber-growing areas of Africa and Asia, and called for closer international co-operation in the development of high-yielding resistant varieties.

In the absence of any suitable method of true vegetative propagation, *Hevea* clones are still multiplied by bud-grafting on to seedling rootstocks. A procedure was described for bud-grafting seedlings considerably younger than those used at present, and an account was given of the successful rooting, under a mist spray, of leafy cuttings of a number of important *Hevea* clones. The commercial value of these new techniques remains to be evaluated, but the rooted cuttings are already providing an important source of uniform material for experiments, such as those on stock–scion effects. Meanwhile, techniques of growth analysis have been developed to give a clearer picture of the effects of rootstocks on scion growth and the variation in the pattern of growth in different clones.

In rubber, as in other crops, the standard method of deciding fertilizer requirements has always been by long-term field experiments. It now appears that leaf and latex analysis may offer an important complementary method. This work, pioneered in Viet-nam, is now being vigorously pursued elsewhere.

As deficiencies in the major elements are corrected, more attention is being paid to the minor ones. It was emphasized that the applications of nitrogen, phosphorus and potassium so often used are inadequate on the generally poor soils of the humid tropics. Magnesium is as important as potassium, and deficiencies in several other elements are known to occur. These factors may greatly affect, and even invalidate, measurement of response to the three main elements.

The tree is now, more than ever, regarded as a part of a complex ecological system, and several papers described the marked effects of different cover species on tree growth. The beneficial effects of creeping legumes were particularly emphasized. Despite the large volume of present work on chemical weed control, there was only a single paper on this subject.

In the sessions on pests and diseases, interest centred on the root diseases, which can cause very serious losses to the rubber grower. One of the difficulties of the plant pathologist in this field was illustrated by a paper which showed that the usually accepted name for the pathogen of the common white root disease of *Hevea*, *Fomes lignosus*, was open to grave objection on taxonomic grounds. The potential hazards of the invasion of the cut surfaces of stumps by wind-borne spores, at the time of replanting, were emphasized, and it was shown that simple and inexpensive procedures could greatly reduce the toll of root disease in rubber plantings. Closely related to this problem is the study of factors affecting the rate of decay of rubber stumps and the role of biological agencies in the removal of this potential source of disease. The possible role of fungicides in the control of root disease was also discussed.

Fundamental work on the raw material of the natural rubber industry, *Hevea* latex, was well represented at the conference. Latex is very far from being a simple suspension of rubber particles in a watery medium. It contains a bewildering array of other particles which are under active investigation, in which use is made of the electron microscope, advanced forms of light microscopy and the ultracentrifuge. Workers in this field now appear to be agreed in regarding latex as a cytoplasmic fluid, and, as these studies develop, it will be interesting to see whether the particles which accompany the hydrocarbon in latex vessels have exact analogues among the known components of other plant cells, or whether they represent hitherto unknown entities.

It is now established that the process of rubber formation occurs within this complex system and it may be made to continue, experimentally, even after the latex has left the tree. An elegant account was presented of the way in which the acetate molecule is converted to rubber hydrocarbon in *Hevea* latex. Members of the conference also heard Prof. Bonner give a striking review of the whole process of rubber biosynthesis and set out suggestions for future research on the unsolved problems of the subject.

The biological complexity of latex is, of course, accompanied by a corresponding chemical diversity. The conference reviewed recent progress in the study of the many substances which accompany the rubber hydrocarbon. As with other fields of biological chemistry, these studies on the non-rubber constituents of latex have gathered momentum in recent years, with the development of new methods of chromatography and electrophoresis.

The biological character and diverse composition of natural latex render it highly susceptible to bacterial attack, and much time and effort have to be devoted to preventing the adverse technological effects which result. The subject is a complex one, and it gave rise to lively discussions during the conference. It appears to be agreed, however, that contamination of the latex begins within the cut ends of the latex vessels themselves and is reinforced at various stages in collection and processing. Measures to control it are already in widespread use and improvements are constantly being sought.

Chemistry and Technology of Rubber Preparation

Knowledge of the structure of the rubber molecule itself is still advancing, and new information is being obtained by the use of the electron microscope and light-scattering techniques. New data were also presented on the variety of reactions which the hydrocarbon can undergo. This reactivity has been turned to advantage to produce modified rubbers, such as the graft polymers. On the other hand, it also leads to the troublesome spontaneous change in properties known as storage hardening. The conference heard an account of a successful method for the inhibition of storage hardening based on a new theory that this change is due to the presence of aldehyde groups.

The bulk of the industry's revenue is still earned by sheet, crepe and other forms of dry rubber. Investigations were reported which should help the producer to avoid defects which down-grade his rubber when it is judged by the almost universal method of visual classification. There were also reports of work aimed at preparing dry rubber in novel forms which would be graded by technological properties rather than by appearance.

Concerning special dry rubbers, the conference heard of the increased interest in 'superior processing' rubbers, which have greatly improved extrusion characteristics. Several papers showed that new advantages and uses are being found and that, with this spur, new low-cost methods of imparting superior processing properties are being discovered. None of the rubbers produced by these alternative techniques possesses the all-round advantages of standard superior processing rubber, but they show promise for applications where the use of the standard product would be uneconomic.

Research and development are encouraging new applications of rubber in many fields. In the textile industry, natural rubber latex is now being used increasingly in the manufacture of non-woven fabrics and in carpet backings. New design methods are enabling engineers to employ rubber components with the same degree of confidence as those of the older structural materials. Further work is also giving road engineers a more detailed picture of the practical benefits to be gained by incorporating various types of rubber into bituminous road-binders.

Testing methods for quality and processability of latex concentrate were described, together with clonal influences on latex foam properties. On the subject of skim rubber, the by-product of the latex concentrate factory, the conference heard how processing methods could affect its properties. Methods for the treatment and utilization of factory effluents were also discussed.

Finally, in his address, 'New Methods of Elastomer Synthesis and their Impact on Natural Rubber", Prof. Gee brought into the open the question that had formed the background to many of the discussions during the week: "Can natural rubber, even when produced by the most economical means, meet the challenge of the new synthetics ?" Prof. Gee's answer was "Yes", provided the natural rubber industry continued and intensified its fundamental research and technical development in the right directions. He showed that no single elastomer is supreme in all respects and that each of them, including natural rubber, can hold its place in the expanding market. He also described the striking results which may be obtained by blending natural and synthetic rubbers and how the presence of the reactive groups influences this blending.

There can be little doubt as to the success of the conference in bringing current ideas on natural rubber research into sharper focus and in stimulating new approaches to the many problems raised. The proceedings of the conference are to be published early in 1961, and those wishing to obtain copies should write to the Director, Rubber Research Institute of Malaya, P.O. Box 150, Kuala Lumpur, Malaya.

ELEVENTH GENERAL CONFERENCE OF WEIGHTS AND MEASURES

THE eleventh General Conference of Weights and Measures was held in Paris during October 11–20 under the chairmanship of M. Barrillon, president of the Academy of Sciences. Thirty-two States were represented at the Conference, which was held at 19 Avenue Kléber, in the former Hotel Majestic now taken over by the Ministère des Affaires Étrangères for use partly as offices and partly as a meeting place for national and international conferences. One epoch-making scientific decision was taken, namely, to re-define the metre in terms of a natural atomic standard, the wave-length of light, thus deposing the platinum–iridium metre bar—the International Prototype Metre—from the supremacy it has held in the field of length measurements since 1889. Three very important administrative and financial resolutions were passed which are crucial to the future development and efficiency of the weights and measures organization. Before dealing with these and other decisions and with an unfinished effort of the Conference to modernize the international treaty on which its authority is founded, it would be well to give a brief outline of the history and development of the whole organization.

International co-operation in scientific metrology depends on the Convention du Mètre, a treaty signed in Paris by the plenipotentiaries of seventeen sovereign States on May 20, 1875. An agreement was thereby made to establish and maintain, at joint expense, a central laboratory and office, known as the Bureau International des Poids et Mesures, with the primary duties of maintaining, improving and extending the use of the metric system. The treaty organization, which the United Kingdom joined in 1884, now represents thirty-eight States (Argentina, Australia, Austria, Belgium, Brazil, Bulgaria, Canada, Chile, Czechoslovakia, Denmark, Dominican Republic, Finland, France, Germany, Hungary, India, Indonesia, Ireland, Italy, Japan, Korea, Mexico, Netherlands, Norway, Poland, Portugal, Rumania, Spain, Sweden, Switzerland, Thailand. Turkey, the United Kingdom, the United States, Uruguay, the U.S.S.R., Venezuela and Yugoslavia (Indonesia and Venezuela joined after October 1960). It acts under the authority of the General Conference of Weights and Measures, constituted by delegations nominated by the Governments of the member-States meeting every six years, with the aid of the International Committee of Weights and Measures—an elected executive body of eighteen members (each from a different State) meeting every two years. This Committee administers the scientific and financial affairs of the Bureau International in between general conferences, drafts recommendations relating to units and standards of measurement with the help now of six expert advisory committees and acts as a steering agency during General Conferences.

The Convention was revised on October 6, 1921, mainly to extend the work of the Bureau International des Poids et Mesures to the standards of electricity and photometry. Up to that date the Bureau International, as custodian of the International Prototypes of the Metre and Kilogramme, was chiefly concerned in its laboratory work with the maintenance, by means of periodical comparisons, of the various national copies of these prototypes issued to the member-States in 1889 and afterwards. The derived standards of volume (or capacity), density and atmospheric pressure naturally came within the responsibilities of the Bureau International ; and, as the length of a material standard is dependent on its temperature, a practical scale of temperature was maintained. As a consequence of the 1921 revision, high-class electrical and photometric equipment was installed at the Bureau International for periodic intercomparisons of groups of standard resistors, standard Weston cells and standard lamps sent in by the national laboratories. In this way, just as for the national metres and kilogrammes, the uniformity of the electrical and photometric standards maintained by the various countries is readily checked, and any individual divergences from the general average which are unusual are identified and reported.

During recent years the rapid development of applications of radioactivity and the ionizing radiations in the scientific, medical and technological fields has created an urgent need for a central standards laboratory to work on the basic metrology of ionizing radiations and to correlate the standards and measuring techniques developed in the national and other specialized laboratories. In 1958 the International Committee established its expert advisory committee for the ionizing radiations which has produced proposals for a new Bureau International des Poids et Mesures laboratory and equipment, together with a general plan of the work to be done and the staff required. Recommendations embodying these proposals were submitted to the eleventh General Conference by the International

Committee, with others for: (1) increasing the staff and modernizing the equipment in existing sections of the Bureau International; (2) changing the rule by which the total annual subvention for maintenance of the Bureau International is apportioned among the member-States. All these recommendations were unanimously adopted and the Conference thereby sanctioned:

(*a*) The creation of a new section at the Bureau International des Poids et Mesures for work on the basic metrology of the ionizing radiations, the construction of a laboratory and the purchase of equipment at an overall cost not exceeding 1,800,000 gold francs (about £210,000).

(*b*) The raising of the total annual subvention made jointly by the member-States from the present figure of about 400,000 gold francs (£47,000) to 900,000 gold francs (about £105,000).

The intentions of these decisions are that the Bureau International, which has hitherto had to work within limits imposed by a much too narrowly restricted budget, should be better able to fulfil its function as a supra-national standards laboratory and to provide it with reasonable funds for this purpose.

To enable the Bureau International to initiate as early as possible the new section on the ionizing radiations, the Ford Foundation has made a grant of 32,500 dollars to cover the period intervening until the new funds voted by the Conference become payable by the member-States on January 1, 1962. The National Research Council of Canada has temporarily seconded to the Bureau International Dr. C. Garrett, head of the Ionizing-Radiations Section of its Division of Applied Physics, who will take charge of the new section during this same period. His duties will include detailed planning of the ionizing-radiations laboratory and the ordering of its equipment; he will also advise the director of the Bureau International des Poids et Mesures on the selection and appointment of staff for the new section.

Despite its partial revision in 1921, the Convention du Mètre retains many clauses, suited both scientifically and politically to nineteenth-century circumstances, which tend to hinder adaptation of the organization to the rapidly changing and complex needs of scientific metrology and international relationships in the twentieth century. Accordingly, a special commission of the International Committee had been working on the draft of a revised treaty since the last Conference in 1954 and this draft had been sent to Governments for comment some months ago. The scientific clauses were easy to settle, but it was soon realized during the eleventh Conference that there was no hope of securing immediate and unanimous approval of the political and administrative clauses of a modernized treaty by the various delegations, so the matter was left to proceed by negotiation through diplomatic channels.

The fundamental scientific resolution unanimously adopted by the Conference re-defined the metre as equal to 1,650,763·73 vacuum wave-lengths of the orange line (6058 Å., spectroscopic designation $2p_{10}$–$5d_5$) emitted by the krypton atom of mass 86. The source of this radiation, recommended in October 1960 by the International Committee, is an Engelhard type of krypton-86 hot-cathode discharge lamp[1,2] enclosed in a cryostat maintained at the triple-point of nitrogen (about 63° K.). The specification of the conditions of excitation and observation ensures a reproducibility of the new optical metre to about 1 part in 100 millions, and there are good expectations of improving on this very soon. Recent experimental work at the National Research Council (Ottawa) and the National Bureau of Standards (Washington) indicates that continuity of the unit metre distance is maintained to the accuracy with which it was represented by the separation, at 0° C., of two parallel defining lines engraved on the prototype platinum–iridium bar, namely, 1 part in 4 millions. Moreover, according to the new definition, the angstrom unit (Å.) becomes equal to 10^{-10} metre exactly[3].

It is interesting to digress here by noting that the Weights and Measures Bill now before Parliament proposes to define the yard as equal to 0·9144 metre exactly. The same value has already been adopted by the National Physical Laboratory (and five other national laboratories) for non-metric measurements of length in science and technology[4]. If the Bill is enacted, the yard for all purposes in Britain will therefore be effectively based on the new primary wave-length standard through the adopted relationship with the metre.

Among other scientific resolutions adopted by the Conference are the following relating to units and standards of measurement:

(1) Ratification of the improved astronomical second of time[5], with a rider urging standards and other laboratories to proceed as actively as possible with the work to establish a second based on an atomic frequency standard.

(2) Provisional retention of the Potsdam gravimetric system[6] for use in physics until the results of certain absolute determinations of gravity now in progress are made known.

(3) Approval of a detailed list of the international system of units[7] (designation *SI*) founded on six basic units (metre, kilogram, second, ampere, degree Kelvin and candela).

(4) Approval of a new draft of the International Temperature Scale (1948)[8], henceforth to be known as the International Practical Scale of Temperature (1948).

(5) Inviting the International Committee to study, and if possible resolve, the confusing situation due to the difference of 28 parts in a million between the cubic decimetre and the litre[9].

The eleventh General Conference was by far the most interesting and stimulating of the three Conferences held since the end of the Second World War. Besides giving official recognition to a fundamental change in the definition of the metre, some very difficult administrative and financial questions were resolved in such a way as should engender a new look for international scientific metrology during the next decade.

This article is published by permission of the director of the National Physical Laboratory, who led the United Kingdom delegation at the eleventh General Conference.

DOMESTIC FOOD CONSUMPTION AND EXPENDITURE IN BRITAIN

THE recently issued annual report of the National Food Survey Committee for 1958 is the ninth in the series of surveys, begun in 1950, of food consumption and expenditure on food in private households in the United Kingdom[*]. During 1958, 8,611 records were compiled from 827 polling districts in England, Wales and Scotland. The survey methods remained unchanged. Information was collected on all foods purchased or brought into the household during one week, but, as before, soft drinks, sweets, ice-cream and snacks were not included, and full details of meals taken away from home not obtained; an allowance has been made for these when the nutritive value of the diet is assessed. Records are no longer sought of changes of larder stocks, these being largely unnecessary for the low-income groups in which daily shopping is traditional. In the higher-income groups bulk purchasing of some items is more frequent, and a large number of households would have to be surveyed to obtain a statistically correct record.

While the survey is thus incomplete on the food consumption side, it provides much valuable information on the expenditure on food and eating habits of the community, set out in a series of well-presented tables which enable the expenditure on many types of foods by families differing in social class, composition and location to be compared.

For Britain as a whole, weekly expenditure on food (with allowances for free and home-grown food) rose from 29*s.* 1*d.* per head per week in 1957 to 29*s.* 4*d.* in 1958. This small increase is attributed to higher seasonal prices. Since 1954, when rationing ceased, the percentage rise in expenditure on food has increased year by year. The report notes that "the average calorie intake of the population has reached such a level that there is little scope for increases in the quantum of purchases except through improvements in quality, service, processing and packing or through increased wastage".

Little change has occurred since 1954 in expenditure on the broad food groups, but within these groups there has been a significant increase in purchases of processed foods such as cakes and biscuits and certain kinds of processed meat, fish, vegetables and fruit. The consumption of butter continues to rise and that of margarine to fall. The steady decrease in expenditure on bread has halted and shows a slight rise, mainly due to the purchase of dearer types of bread.

On the average there has been little change in the nutritive value of the average British diet since 1954. When compared with the allowances recommended by the British Medical Association, it is found to be satisfactory. Supplies of nearly all the nutrients are, however, greater in the higher- than in the lower-income groups. In the latter, supplies of protein are lower than the British Medical Association's recommended allowance for households, with total incomes of less than 230*s.* a week, and old-age pensioners may be somewhat short of iron. No data are available indicating that these deficiencies affect the health of the groups in question.

A chapter on geographical differences in food purchasing contains some interesting information. For example, in Scotland expenditure on cakes and biscuits was 36 per cent more than the average, and that on flour 40 per cent less than the average. Welsh households spent 30 per cent more than the average on flour, 60 per cent more on butter and 12 per cent less on cakes and biscuits.

Two new special studies were included in the 1958 survey. One deals with the effect on the household diet of the housewife's employment, which causes a change in the whole pattern of eating habits with more meals and snacks taken away from home. The results of this study were inconclusive, because of the difficulty in obtaining information about outside meals, and elaborate statistical treatment was scarcely warranted. The second special study was concerned with the food consumption of households dependent on one woman with no other wage-earner, and here the information collected was disturbing. The diets were in general less than the average in nutritive value, particularly in protein and calcium content, and, in the larger families so dependent, there was also a deficiency in calcium and riboflavin.

While the picture is on the whole satisfactory, the data for larger families check complacency. In households of two adults and two or more children, protein supplies are less than the British Medical Association's recommended allowances, and when there are four or more children the diet falls short of the allowance not only with respect to protein but also in calorie value and calcium and riboflavin content. The fact that these figures are an average for large families of all income groups means that consumption in the lower-income groups in this category is far less than the average for the whole groups of households surveyed.

IMMUNIZATION IN INDIA

IN a recent issue of the *WHO Chronicle* the possible part that could be played by wide-scale immunization against disease in India, provided outside support is given, is considered (14, No. 11; November 1960).

About 13·5 per cent of India's 408 million inhabitants are infants and children of 4 and under; about 25 per cent are between 5 and 15 years old. Diphtheria, whooping cough and tetanus cause widespread morbidity and mortality in these age groups. Diphtheria—also rife in rural areas—is responsible for between 2,000 and 5,000 admissions every year to hospitals in cities such as Calcutta and Bombay, and no fewer than 84 per cent of the cases are children between 2 and 10 years of age, while 11 per cent are infants. Investigations have shown that tetanus (including that of the new-born) is an important cause of death in rural India. Whooping cough not only causes much suffering but also many deaths from secondary complications.

In 1959, the twelfth session of the World Health Organization Regional Committee for South-East Asia recommended the routine vaccination of children against all three diseases. The major obstacle to this course in India has hitherto been the difficulty of obtaining the necessary vaccines ; local production is inadequate and the cost of importing them prohibitive. It has therefore been decided to expand their local manufacture with help from the World Health Organization and Unicef as a preliminary to a country-wide immunization campaign against these three diseases.

A pilot unit for the production of the vaccines will be set up at the Central Research Institute, Kausali. As soon as practical methods of preparation have been worked out, standardized and tested, other laboratories will be encouraged to adopt the approved methods and start production so that the entire needs of the country can be met step by step. At the same time, epidemiological information on the diseases will be collected from both rural and urban areas and used to plan a practical and economical immunization programme for the whole country. The vaccines will be manufactured at Kausali in accordance with procedures recommended by the World Health Organization, and a consultant from that Organization will be assigned to the project. Equipment, apart from that already available in the country, will be supplied by Unicef.

Two workers from the Kausali Institute are at present in Australia studying vaccine production and immunology, including the production of triple vaccine against diphtheria, whooping cough and tetanus. On their return to India they will work with the staff of the special vaccine production unit. Another worker from the Institute will be trained overseas at a later date. It is expected that the Institute will be able to produce 4,000,000 ml. of vaccine a year to begin with, and within three years will reach the target of 7,000,000 ml. a year.

DISTRIBUTION OF CERTAIN POPPY-FUMARIA ALKALOIDS AND A POSSIBLE LINK WITH THE INCIDENCE OF GLAUCOMA

By Drs. SOHRAB A. E. HAKIM, VALERIE MIJOVIĆ and JAMES WALKER

National Institute for Medical Research, Mill Hill, London, N.W.7

GLAUCOMA, suddenly affecting large numbers of people and associated with dropsy ('epidemic dropsy'), has occurred sporadically in India in epidemic form, and these epidemics were eventually traced[1] to the contamination of cooking oils with the seed-oil of the common prickly yellow poppy, *Argemone mexicana* L. Since epidemic glaucoma in India was caused by a plant poison, it was suggested[2] that endemic (primary) glaucoma of unknown ætiology, occurring in other parts of the world, might also result from some toxic cause. Endemic glaucoma, empirically recognized for centuries, is one of the major causes of blindness, and Duke-Elder[3-5] has repeatedly emphasized that, in spite of extensive researches, its basic cause, mechanism, and radical treatment remain unknown. Glaucoma is symptomless during the greater part of its relentless development, and in its early stages merely shows as an increase in the normal range of fluctuation in the fluid tension of the eye. Only later is the tension permanently raised, accompanied by progressive, perhaps independent, degeneration of the drainage mechanism and nervous structure of the eye[3,6,7]. In spite of facilities for early detection and medical and surgical treatment available in advanced countries, such as the United Kingdom, nearly 60 per cent of cases proceed to total blindness[8].

The seed-oil of *Argemone mexicana* contains the *iso*quinoline alkaloids sanguinarine and dihydrosanguinarine[9], and we[10a,b] have described elsewhere an investigation of the biological effects of argemone oil and of sanguinarine. In particular, the production of experimental glaucoma and dropsy was described, and both these cardinal signs of the human epidemic disease were reproduced in animals for the first time. Sanguinarine, a pure alkaloid, was thus the first known naturally occurring substance successfully used as a tool for the production and study of experimental glaucoma. Eye-tension-raising properties were, however, not restricted to sanguinarine and to argemone oil. Tests on a large group of rabbits established that the closely related alkaloid chelerythrine, and oils or watery extracts of seven other species of poppies also raised eye tension[10]. These observations of ours led others[11] to investigate in rabbits the effects on eye tension of a number of *iso*quinoline alkaloids belonging to various types ; besides sanguinarine, the intravenous injection of codeine, papaverine, narcotine, bulbocapnine, corydine, corybulbine, and chelidonine also produced acute rise of eye tension[11]. Our own experiments were continued[12] in India with rhesus monkeys, as their eyes more closely resemble those of man. Repeated injections of sanguinarine produced dropsy and sustained rise in eye tension, while feeding with argemone leaves, or with seed-oil of either argemone or the Indian fumitory (*Fumaria indica* Pugsl.), produced dropsy and a smaller rise in eye tension.

Sanguinarine is a member of the small benzophenanthridine group of *iso*quinoline alkaloids. Although isolated[13] in 1829 from *Sanguinaria canadensis* L., it had, up to the time the present work was begun in September 1956, been detected in only nine species of poppy-fumaria weeds [*Argemone mexicana* L. ; *Bocconia pearcei* Hutchinson ; *Chelidonium majus* L. ; *Dicranostigma franchetianum* Hook. f. et Thoms. ; *Eschscholtzia californica* Cham. ; *Glaucium flavum* Crantz. (=*G. luteum* Scop.) ; *G. fimbrilligerum* Boiss. ; *Macleaya microcarpa* Fedde (=*Bocconia microcarpa* Maxim.) ; *Sanguinaria canadensis* L.], while its occurrence in three other species (*Bocconia cordata* Willd. ; *Dicentra spectabilis* L. ; *Stylophorum diphyllum* Nutt.) was not confirmed[14,15]. While our work was in progress, its presence in *Glaucium corniculatum* Curt. was recorded by Slavík and Slavíková[16], and, since our work was completed in March 1958, the painstaking researches of Slavík and his collaborators have demonstrated its presence in *Dicranostigma franchetianum* Fedde[17], *Dicentra spectabilis* L.[18], *Glaucium flavum* var. *fulvum* Fedde[19], *G. vitellinum* Boiss. et Buhse[20], *G. elegans* Fisch. et Mey.[21], *Argemone alba* Lestib.[22], *Meconopsis aculeata* Royle, *M. rudis* Prain, *M. paniculata* Prain, *M. betonicifolia* Franch., *M. horridula* Hook. f. et Thoms., and *M. latifolia* Prain[23]; a few of these observations confirm, and they are in general complementary to, those recorded in the present article.

The meagre information hitherto available on the distribution of sanguinarine may be attributable to difficulties in adequate extraction and identification, since sanguinarine and some of the other alkaloids with which we are concerned show somewhat unusual partition properties and are not detected by several of the common 'general' reagents for alkaloids. Fortunately, these alkaloids fluoresce brilliantly in distinctive colours in filtered ultra-violet light, and the fluorescences show individual and characteristic changes in colour with change of *p*H. They could be separated either by paper chromatography or by paper electrophoresis and detected even in exceedingly small quantities by their fluorescences, R_F values, and relative speeds of migration. Paper chromatographic runs were made by descending flow on Whatman No. 1 paper using *n*-butanol/glacial acetic acid/water (63 : 10 : 27 or 100 : 10 : 30); second dimensional runs were made with a similar mixture (85 : 1 : 14)[24]. In filtered ultra-violet light, sanguinarine spots fluoresced with a bright orange colour, chelerythrine and coptisine spots with a golden yellow colour, and berberine spots with a brilliant yellow-green colour; touching the spots on the paper with a glass rod previously dipped into *N* sodium hydroxide produced characteristic reversible changes in fluorescence. Paper electrophoresis runs were made on Whatman No. 54 strips, 12·5 cm. wide, moistened with 10 per cent formic acid[25], with a potential difference of 1,000 V. and a potential gradient of 20 V./cm., using sanguinarine, or berberine, as marker.

Herbs of the families Papaveraceae and Fumariaceae were gathered from the Royal Botanic Gardens, Kew, the University Physic Garden, Oxford, and from India. Different parts of each plant were ground in small volumes of glacial acetic acid, which was found to be the best extraction medium. The alkaloids in such extracts were easily and clearly separated by paper chromatography and paper electrophoresis[10c]. From a few drops of plant extract, ten or more fluorescent spots were frequently obtained by either method. Chromatographically separated fluorescent spots were eluted and re-spotted for electrophoresis for confirmation of their basic nature and identity. With these very sensitive methods, numerous fluorescent alkaloids were readily separated from even a few milligrams of plant material in suitable cases, and the results are recorded in Table 1 for the distribution of four of the principal alkaloids (berberine, coptisine, chelerythrine and sanguinarine) between the roots, stems, leaves, flowers, capsules, and seeds—or such of these parts as were available to us—of the species examined. Separation of alkaloids present in gram quantities of plant material could also be effected on small alumina columns developed with benzene, acetic acid and ethanol[24].

Sanguinarine was found in 49 out of the 53 available species of poppy-fumaria weeds and usually in several different morphological parts of the plant (Table 1). Far from being restricted to only a few genera of poppy-fumaria plants as previously believed[16], it was perhaps the commonest fluorescent alkaloid detected among these weeds. It was almost invariably found in the leaves and stem. When the same species was collected from different localities, or at different stages of its growth, small qualitative and quantitative variations were noted in the alkaloidal content. Chelerythrine was found less frequently than sanguinarine; it was common in certain genera and rare in others. Berberine, though of fairly frequent occurrence in poppy-fumaria plants, was restricted to certain genera with rare exceptions. Sanguinarine and chelerythrine were not detected in a few specimens from the phylogenetically related family Berberidaceae, in which berberine was abundant in the stems yet absent from the leaves. Canadine was rarely detected. On the other hand, the closely related protoberberine alkaloid coptisine was very often seen. The more widespread occurrences of sanguinarine and coptisine that have emerged from the present work are of great interest, but perhaps not altogether surprising, as protopine is said to be without doubt the most widespread of all alkaloids and to have been found in all papaveraceous plants which have been exhaustively examined[15,27], and sanguinarine, coptisine, and protopine probably share, according to widely accepted views on alkaloid biosynthesis[28,29], a common protoberberine precursor.

We have found sanguinarine in the root, stem and leaves of the 'opium' poppy (*Papaver somniferum* L.) but not in the capsule or in the seeds. It is presumably not present in opium as it has not been noticed in spite of intensive studies on the alkaloids of opium[27] during the past hundred years. In Persia young opium plants pulled up to prevent excessive cropping are used as pot herbs[30] and are fed to cattle. Although we failed to detect sanguinarine in the specimen of *P. somniferum* seeds examined, the culinary use of poppy seeds (maw seed, *P. somniferum* L. var. *nigrum* DC.) should be viewed with suspicion, as we examined a poppy-seed cake purchased in a London supermarket and found it to contain several fluorescent bases and a small but quite unmistakable proportion of sanguinarine. Poppy seeds and their oil are extensively used in bread and confectionery in France, south-east Europe, and western Asia, especially by Jews, who, as a people, have a notably high incidence of glaucoma[31,32]. Insidious sanguinarine poisoning could occur from various species of poppy seeds, especially those of *P. rhoeas* L., which have a tendency to adhere to cereals to the extent of up to 10 per cent. These seeds are also fed to poultry as 'tail-corn', and probably transmit their alkaloids to eggs. Through the courtesy of Dr. M. E. Langham and Dr. J. G. Dobbie of the Medical Research Council Ophthalmological Research Unit, Institute of Ophthalmology, we have been able to examine the eggs from hens forcibly fed with sanguinarine, using the hydrolytic-extractive procedure described in the following article; we found sanguinarine in the whites and traces in the yolks along with other fluorescent bases, none of which was found in control eggs.

Sanguinarine was found in nearly all the 53 species of poppy-fumaria weeds which we examined. These species are distributed among 14 genera, and this suggests that sanguinarine is probably present in many more of the 675 species[33] of this vast alkaloid-rich family with its world-wide distribution. In view

of the much wider distribution of this toxic alkaloid than has hitherto been suspected, the attendant risks of contamination of milk and other foodstuffs become more obvious. Many of the traditional uses of poppy-fumaria products in various parts of the world, particularly their inclusion in medicaments, are dangerous and should be carefully reviewed. It is obvious that, while sanguinarine was the first pure substance observed to produce glaucoma experimentally[10], many other substances can probably do so in varying degrees[10,11], and the possibility that endemic primary glaucoma results from chronic poisoning with some substance or another should be borne in mind. Such chronic poisoning could arise by the innocent ingestion of the responsible agent or could be the unrecognized side-effect of drugs used for legitimate therapeutic purposes. The present communication reviews the distribution of sanguinarine and related alkaloids in Nature, and points to the likelihood of their transmission to man in food and drugs, while milk as a possible vehicle is considered in the following article.

We are indebted to Drs. R. H. F. Manske, J. Slavík and L. Slavíková, and to Prof. F. Kuffner for alkaloidal reference specimens; to Dr. N. Bor and Dr. J. Hutchinson at the Royal Botanic Gardens, Kew; to Mr. G. Robinson of the Oxford University Physic Garden; and to Father H. Santapau, director of botany, St. Xavier's College, Bombay, for their suggestions and for numerous poppy-fumaria specimens. One of the authors (S.A.E.H.) is grateful to Sir Charles Harington for the opportunity of working at the National Institute for Medical Research, to the Wellcome Trust for financial support, and, above all, to Lady Mellanby and the late Sir Edward Mellanby for unfailing help and encouragement.

EXPERIMENTAL TRANSMISSION OF SANGUINARINE IN MILK: DETECTION OF A METABOLIC PRODUCT

By Drs. SOHRAB A. E. HAKIM, VALERIE MIJOVIĆ and JAMES WALKER

National Institute for Medical Research, Mill Hill, London, N.W.7

DIETARY factors are known to affect the quality of milk, and taints and off-flavours are often caused by the ingestion by cows of a variety of weeds, perhaps the most familiar being the taint acquired by cream and butter made from the milk of cows that have eaten cruciferous plants. Milk, however, probably always contains, in trace amounts derived from the pasture or other feeding-stuffs, undesirable substances that do not declare their presence as frankly as those that produce taints. Our present concern is with the possibility that toxic poppy-fumaria alkaloids, and sanguinarine (I) in particular, may be transmitted to man in milk from cattle grazing on pastures containing poppy-fumaria weeds, as we have previously suggested[1], and we wish to report some model experiments in that connexion. A striking example of the transmission of toxic alkaloids in milk has recently been given by Schoental[8], who found that the administration of certain *Senecio* alkaloids to the lactating rat produced fatal liver lesions in the young without having any apparent effects on the mother or on her lactation, and she further made the suggestion that various liver disorders in childhood may be the result of poisoning by milk.

Evidence supporting the possibility of transmission of argemone alkaloids in milk was first obtained in India when argemone leaves were added to a goat's diet. Some toxic substance was obviously absorbed and transmitted, for feeding the goat's milk to four rhesus monkeys produced a rise in their eye-tension. A further experiment was made to determine if still higher levels of eye tension could be reached and maintained by reducing the cysteine content of the poisoned goat's milk. This was based on the human epidemiological records which showed that argemone poisoning was more severe in poorly fed communities and on our earlier animal experiments in which cysteine had diminished or prevented the toxic effects of sanguinarine[1a]. Four monkeys were fed on a synthetic diet low in cysteine, prepared with the casein-fat portion of the toxic goat milk; in two animals the basic tension rose to much higher levels and decreased only slightly after about eight weeks. The results obtained with these monkeys confirmed the theoretical possibility that milk can transmit poisons that raise eye tension[1b]. Argemone leaves contain traces of sanguinarine together with other *iso*quinoline alkaloids (ref. 3 and preceding article), and it is possible that other alkaloids, also secreted in the goat's milk, contributed to produce the rise in eye tension observed in the above experiments. The goats, in spite of producing milk toxic to monkeys, showed only a slightly raised eye tension, and, as a species, goats are known to be resistant to certain other poisons[4].

In the experiments now to be described milk was examined by the following methods: (1) *Dialysis*. The milk was diluted, brought to the mean isoelectric point of its proteins, and dialysed through 'Cellophane'. The dialysate was concentrated under reduced pressure, acidified with acetic acid, and continuously extracted with chloroform for several hours. The aqueous phase was then made alkaline with sodium hydroxide solution, re-extracted continuously with chloroform, and finally with ether. The extracts were evaporated, and the combined residues were spotted on paper for chromatography or electrophoresis in the manner described in the preceding communication. (2) *Acid hydrolysis*. The milk was heated with an equal volume of 3 *N* hydrochloric acid at 100° C. for 4 hr., and the cooled mixture was then extracted continuously with organic solvents at both acid and alkaline *p*H as described in the preceding method. When sanguinarine was artificially added to control milk, the quantities afterwards recovered by dialysis were small, but acid hydrolysis led to greater recovery.

Lactating rabbits (2·5–3·0 kgm.) were separated from their young and injected subcutaneously in the flank with 4–8 mgm. of sanguinarine chloride in aqueous solution. At varying intervals during the next 4 hr., 5–10 units of oxytocin were injected, and the rabbits were milked by intermittent suction and massage. The milk was then processed as described above, and the extracts were examined by paper chromatography and paper electrophoresis. In four out of ten samples of rabbit milk obtained after injections of sanguinarine the alkaloid and a green-fluorescing metabolic product were detected by both methods. Several other weaker fluorescent spots, presumably representing other metabolic products, were also seen. All these were absent from control experiments with normal rabbit milk. The properties of the green-fluorescing metabolic product are discussed here.

With the assistance of Dr. D. R. Bangham, we succeeded in separating and detecting sanguinarine in as little as 1–2 ml. of the milk of rabbits injected with this alkaloid. The milk was electrophoretically differentiated on a column of 'ethanolysed' cellulose[5] in phosphate buffer, and collected serially in 50 fractions. Sanguinarine could only be detected after hydrolysis of the samples, and only in the albumin fractions. Many alkaloids are known to be strongly adsorbed on to serum albumin, and this was found to be the case for sanguinarine. After injecting sanguinarine into rats, cats and monkeys, 1 ml. samples of their plasma were collected and separated electrophoretically. As with the milk, sanguinarine was only found after acid hydrolysis and only in those fractions which contained serum albumin. Although present in most of their viscera, the maximum recovery of sanguinarine was from the liver.

In collaboration with Dr. A. H. Gordon we found that sanguinarine was converted in the liver into the green-fluorescing metabolic product. Sanguinarine chloride (1·8 mgm. in 5 ml. normal saline) was added to blood (50 ml.) which was mechanically circulated for 4 hr. through the isolated liver of a rat[6]. Blood samples were taken after 10, 30 and 60 min. and at the end of the experiment. All samples were hydrolysed with hydrochloric acid in the manner described above, and the hydrolysis mixtures were made alkaline with sodium hydroxide and extracted with chloroform. The residues from the chloroform extracts were taken up in about 0·5 ml. of chloroform-glacial acetic acid and spotted for electrophoresis on paper in 10 per cent formic acid. No sanguinarine was found at all, but the green-fluorescing substance was present in the 4-hr. specimen and there may have been a trace in the 60-min. specimen.

Properties of the Green-fluorescing Metabolic Product

This substance was best obtained from the urine of rabbits injected with sanguinarine chloride (I). Two rabbits were kept in metabolism cages and received injections of sanguinarine chloride (8 mgm.) daily for 5 days a week for 6 weeks and the urine was collected. The urine (2·5 l.) was acidified with concentrated hydrochloric acid (200 ml.) and heated on the water-bath for 2 hr. with the addition of an anti-foam. The cooled mixture was basified with sodium hydroxide solution and extracted with chloroform (about 1·5 l.). The emulsified organic phase was shaken with water until neutral and then stirred with anhydrous sodium sulphate until a clear chloroform solution was obtained. This process of extracting the hydrolysed urine was repeated four times. The residue obtained on evaporation of the combined chloroform extracts was applied to a column of alumina (activity I/II) (100 gm.), and eluted with benzene–acetic acid. The first fraction was shown by paper electrophoresis to contain the green-fluorescing material and several other fluorescent substances; none of these was observed on similar treatment of the urine from control rabbits receiving the same diet. The fraction containing the green-fluorescing substance was further purified by solution in benzene and extraction with 20 per cent hydrochloric acid. The acid solution was basified and extracted with chloroform. The chloroform solution was shown by paper electrophoresis to contain the green-fluorescing substance, and the material was chromatographed in dry benzene on alumina (10 gm.) as before. The first fraction, coming off the column as a blue-violet fluorescing solution, deposited a few minute colourless needles on evaporation and contained the substance sought as the sole fluorescent material (green on paper electrophoresis in acid solution); it was also present in the second fraction together with a substance showing a blue fluorescence on the acid paper electrophoresis strip, but none was present in subsequent fractions, which contained still more fluorescing substances (violet, blue) as shown by paper electrophoresis. The green fluorescing sub-

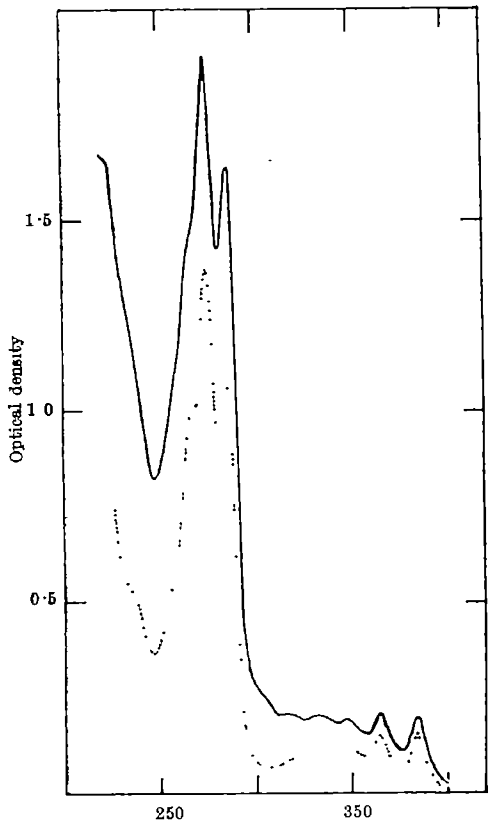

Fig. 1. Ultra-violet absorption spectra in spirit. —— green-fluorescing metabolic product, extracted from paper electrophoresis strip (concentration unknown); . .... 3,4-benzacridine (0 42 mgm./100 ml.)

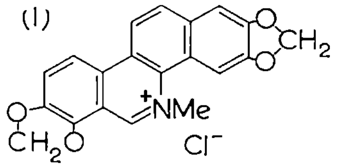
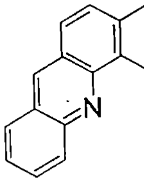
stance possessed numerous properties identifying it with a high degree of certainty with 3,4-benzacridine (II). A reference specimen of the latter substance was available *via* a hydrogenated derivative formed as a by-product in the preparation[7] of 3,4-benzophenanthridine, and it was later obtained by two unambiguous syntheses[8,9]. The ultra-violet absorption spectrum of the solution obtained by eluting the green-fluorescing metabolic product from the paper electrophoresis strip with ethanol showed a remarkable degree of correspondence with that of 3,4-benzacridine [(II) (Fig. 1); and our colleague Dr G. H. Beaven, who kindly examined the spectra of the two substances for fine structure by the logarithmic cam method[10] in ethanol both before and after the addition of 0·01 *N* hydrochloric acid, reported that the fine structure bands were identical in the spectra of the two substances. The metabolic product and 3,4-benzacridine showed identical behaviour on paper chromatograms and on paper electrophoresis strips, and the fluorescences of the two substances on paper were indistinguishable under acid (green) and alkaline (blue) conditions. Through the courtesy of Prof. R. T. Williams, St. Mary's Hospital Medical School, we were able to compare the fluorescence excitation and emission characteristics of the metabolic product eluted from paper electrophoresis strips with those of 3,4-benzacridine similarly treated using the Aminco-Bowman spectrophotofluorimeter. In 0·1 *N* hydrochloric acid both substances showed activation spectra with maxima at 305 and 390 mμ, exciting fluorescence with a single maximum at 495 mμ; when the solutions were made alkaline with sodium hydroxide a maximum in the activation spectra of both substances appeared at 300 mμ, exciting fluorescence with a maximum at 430 mμ. With a stronger (alkaline) solution of 3,4-benzacridine it was possible to observe another maximum in the activation spectrum at 390 mμ, but light-scattering prevented its observation with the weaker solutions obtained by eluting paper electrophoresis strips.

With so many criteria of identity satisfied, there can thus be little doubt that the metabolic product was indeed 3,4-benzacridine (II), and, if it arose from sanguinarine (and that conclusion seems inevitable), it must have resulted from a profound metabolic alteration for which we know of no close analogy. We have no precise measure of the extent of the conversion of one into the other, but it must be quite small. N-Demethylation calls for no comment, but, in addition, the oxygen functional groups have disappeared and a rearrangement of the carbon skeleton has taken place. Enzymic fission of alkyl aryl ethers[11,12] and metabolic dehydroxylation[11,13] are both well established metabolic reactions, so that the loss of the oxygen functional groups in the present instance may be regarded as extensions of these processes. The rearrangement of the carbon skeleton in passing from sanguinarine chloride (I) to 3,4-benzacridine (II) is possibly also not as bizarre as it would appear at first sight, as there are analogies *in vitro* in the dienone-phenol rearrangement[14], in the anthrasteroid rearrangement[15,16] and in the recently announced conversion of picene into 1,2:5,6-dibenzanthracene[17]. In each of these conversions one part of a condensed ring system exchanges its position of fusion with respect to the rest of the system for an adjacent position, and although only the last of these occurs in a fully aromatic system they presumably all proceed by way of transient spirocyclic intermediates and successions of 1,2-shifts[14,18,19]. A mechanism involving ring-chain tautomerism of an intermediate reduced derivative is, however, not excluded for the metabolic conversion of sanguinarine chloride.

(I)





(II)

It is obvious from these experiments that sanguinarine, together with some of its metabolic products, can be secreted in traces in rabbit milk, and application of the sensitive methods of detection developed in this and in the preceding communication to the milk of goats that have been fed on *Argemone* leaves has now shown the presence of small amounts of sanguinarine in such milk also. Considering the cosmopolitan distribution of poppy-fumaria weeds and the regularity with which sanguinarine occurs in these plants, the likelihood of traces of sanguinarine and of other toxic alkaloids finding their way into milk supplies intended for human consumption must be quite considerable. Under field conditions and in good pastures the unpleasant odour and taste of various *Papaver* spp. render these plants objectionable to animals[19], which frequently show considerable discrimination in their eating habits, but it is otherwise with hay and silage. On the other hand, the common fumitory (*Fumaria officinalis* L.), which is widely distributed and fairly common, is readily eaten by cows though not by goats[20]. Under adverse conditions and in poor neglected pastures cattle are obliged to feed more indiscriminately and the likelihood of alkaloidal contamination of milk in such circumstances must be considerably greater. Whether or not these observations have a bearing on the incidence of endemic primary glaucoma cannot at present be assessed, and they are merely offered as circumstantial evidence to show that regular unintentional absorption of minute amounts of sanguinarine and of other papaveraceous alkaloids by man is feasible.

We wish to thank Dr. D. R. Bangham, Dr. G. H. Beaven, Dr. A. H. Gordon and Prof. R. T. Williams for their generous assistance. One of the authors (S.A.E.H.) is grateful to Sir Charles Harington for hospitality at the National Institute for Medical Research, to the Wellcome Trust for financial support, and to Lady Mellanby and the late Sir Edward Mellanby for their help and encouragement.

MAMMARY CANCER INDUCED BY A SINGLE FEEDING OF POLYNUCLEAR HYDROCARBONS, AND ITS SUPPRESSION

By Prof. CHARLES HUGGINS, LORRAINE C. GRAND and FILOMENA P. BRILLANTES

Ben May Laboratory for Cancer Research, University of Chicago

ONE of the most remarkable experiments in cancer research is the induction of cancer which occurs preferentially in the breast of rats following the feeding of carcinogenic hydrocarbons. The first compound found to incite mammary cancer by this method was 2-acetylaminofluorene (2-AAF) which was incorporated in a diet that was fed to rats for many months[1]. The repeated daily administration of 3-methylcholanthrene (3-MC) to young adult female rats of a special strain induced mammary cancer invariably and rapidly[2,3]; the earliest cancer of the breast was detected by palpation 20 days after beginning the feeding, and within two months every animal had developed multiple tumours of this sort. A newly recognized property[2] of the mammary cancers induced by this method was the dependence of many of the tumours on the presence of hormones, since regression takes place after ovariectomy or certain other endocrine procedures. This is a characteristic that is commonly observed in cancer of the breast in human beings, but which is unique among mammary cancers available in the laboratory.

It will now be shown that a single feeding of polynuclear hydrocarbons to rats caused selective injuries in the recipient rather than total body damage. These lesions include the induction of leukopenia and of cancers of two types, carcinoma of the breast and of the external acoustic duct. Further, established mammary cancers were suppressed in many rats by treatment with certain hormones or by pregnancy.

The induction of mammary cancer following the application of aromatic carcinogens remotely from the breast was first observed by Maisin and Coolen[4] who painted the skin of mice with 3-MC and observed a high incidence of cancer of the breast in addition to cancer of the skin. A single intramuscular injection of carcinogenic hydrocarbons is a classical method of evoking sarcoma in susceptible rodents[5]. An injection of 3-MC into the breast of mice gave rise to sarcoma and adeno- and squamous carcinoma of the mammary glands[6]. A single intravenous dose of urethane gave rise to benign pulmonary tumours in mice[7].

Induction of Mammary Cancer

Female rats of the Sprague–Dawley strain were used in all the experiments, with 10 rats in each experimental group; unless stated otherwise, the animals were age 50 days and weighed 140–150 gm. when the hydrocarbons were fed. They remained free from respiratory diseases.

With the aid of gentle heating, 2 gm. of 7,12-dimethylbenz(a)anthracene (DMBA), or 1·5 gm. of 3-MC was dissolved in 100 ml. of sesame oil. One gram of 2-AAF was dissolved in 10 ml. of ethanol and the solution was diluted to 100 ml. with sesame oil. The solutions were instilled in the stomach through a soft rubber catheter, and only a single dose was administered. The rats were examined frequently for palpable tumours for 150 days and cancers weighing 10 mgm. or more were readily detected. The occurrence of the cancers was dated from the day of feeding the carcinogen. The tumours were confirmed at necropsy when the total number of visible tumours ('active centres') was counted.

In our rat colony two 'spontaneous' mammary cancers have been observed among about 20,000 untreated female rats less than eight months of age. But benign mammary tumours occur very frequently in this strain in senescence[8].

3-*Methylcholanthrene*. A single feeding of 3-MC (100 mgm.) induced cancer in 100 female rats, aged 50–65 days, in 10 consecutive series; no tumours were observed in 20 males treated similarly. The rats suffered a decline in body-weight (total loss 10–15 gm.) for 48 hr. after the feeding, but a gain in weight was observed on day 3. In these series of females, mammary cancer was observed in every rat and squamous carcinoma of sebaceous glands adjacent to the external auditory canal in two of them; no other tumours were found. The earliest mammary cancer was detected by palpation on day 31, and the last was observed on day 130. But in serial histological sections of the inguinal mammary glands of 10 rats, 14 days after a single feeding of 3-MC, carcinomata were found in two of the glands on microscopic examination. The squamous carcinomata of sebaceous glands appeared, respectively, on days 109 and 121.

The influences of age at the time of a solitary feeding, and of the presence of the ovaries, were investigated by feeding a single dose of 3-MC (66·6 mgm./100 gm.) to rats of various ages; half the animals were intact, and the ovaries of the others had been removed at the time of weaning. In the intact rats mammary cancer was induced by feeding the carcinogen at age 23 days and the incidence of tumours rose progressively with age until all rats fed 3-MC at age 50 days developed cancer of the breast (Table 1). There was a decline in the incidence of mammary cancer in rats fed 3-MC at age 75 days, and cancer of the breast developed in only a small number of animals fed 3-MC at age 100–365 days (Fig. 1).

No mammary cancer was observed in 100 rats that had been ovariectomized at age 22 days and fed a single dose of 3-MC thereafter at various ages between 23 and 100 days.

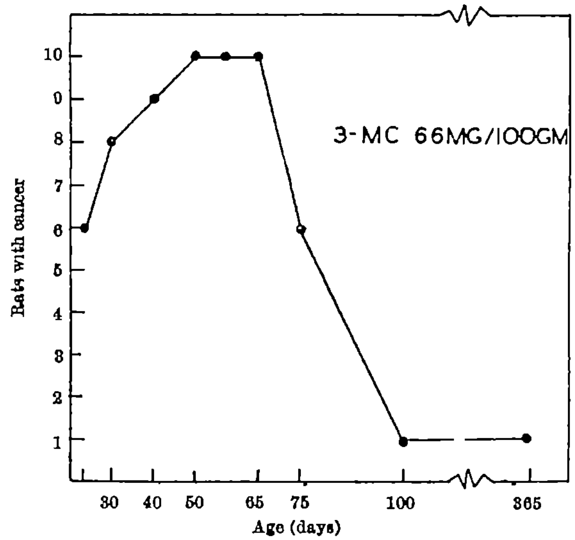

Fig. 1. Incidence of mammary cancer in groups of ten rats fed 3-MC once only. The abscissa indicates the age when the compound was fed

Table 1. INDUCTION OF MAMMARY CANCER BY INTRAGASTRIC INSTILLATION OF POLYNUCLEAR HYDROCARBONS AT 50 DAYS OF AGE

Compound	Dose (mgm.)	No. with cancer*	Appearance of palpable tumours (days)			Active centres
			range	median	mean	
DMBA	20	10	28–59	41	42·8±10†	6·8
DMBA	15	10	34–70	49	48·5±11	3·0
3-MC	100	10	31–86	50	51·3±16	2·8
3-MC	50	8	35–121	56	61·4±30	1·1
3-MC	25	7	34–54	49	47·5±9	2·4
3-MC	10	3	45–129	52	75	1·3
3-MC	5	2	50 and 133	—	—	1·0
3-MC	2	1	48	—	—	1·0
2-AAF	100	3	43–73	53	56·3	1·0
2-AAF	50	8	51–79	59	63	1·0

* There were ten rats in each group. The animals were observed for 150 days.
† Standard deviation.

The optimal dose of 3-MC for the induction of mammary cancer after a single feeding was 100 mgm.; this dose induced 1–4 active centres in each rat. A single dose of 3-MC (2 mgm.) induced mammary cancer in one rat and there was a progressive increase in the rate of tumour incidence and in the number of active centres with augmentation of the dose until the optimal amount was reached (Table 1).

A large portion of 3-MC which is fed passes through the alimentary tract. After a large dose the fæces were highly fluorescent. Our colleagues, Dr. Flesher and Dr. Sydnor, fed a single dose of tritium-labelled 3-MC (10 mgm.) to rats and recovered about 90 per cent of the administered radioactivity in the fæces, where significant quantities were detected for 7–11 days following the single feeding[9].

Trace amounts of 3-MC are sufficient to induce mammary cancer. Compressed, cylindrical pellets of known weight were implanted in the spleen of 18 rats; neoplasms did not arise in the spleen but three of the animals developed mammary cancer at 105, 148 and 199 days respectively. At necropsy, the pellets were removed from the spleen, blotted, heated to 100° for 24 hr. and re-weighed. No decrease in weight of the 3-MC pellet occurred during the long sojourn in the spleen. In one of the experiments wherein a rat developed mammary cancer at 148 days after implantation of 3-MC in the spleen, both the original and final weight of the pellet was 26·8 mgm. An amount of 3-MC too small to be detected on our balance had induced mammary cancer. Shear[5] observed formation of sarcoma in muscle after implanting therein a pellet of cholesterol containing dibenz(a,h)anthracene (0·4 μgm.).

7,12-*Dimethylbenz*(*a*)*anthracene*. A single feeding of DMBA was highly effective in the induction of mammary cancer in female rats. DMBA (1 mgm.) induced mammary cancer, and there was a progressive rise in the incidence of cancers with increased dosage until the optimal dose was reached (Fig. 2). The optimal dose of DMBA (dissolved in sesame oil, 1 ml.) for induction of mammary cancer by a single feeding was 20 mgm. For: (1) every rat survived; (2) mammary cancer developed in 40 consecutive rats without exception; (3) the first cancer was detected by external examination at 28 days and all the rats had visible tumours of the breast before 60 days; (4) the number of active centres in individual rats varied from 3 to 21, the average being 6·8. DMBA (15 mgm.) induced mammary cancer in every rat after a single feeding, but there were fewer active centres than in rats which had received 20 mgm. (Table 1). All 10 rats which were fed DMBA (50 mgm.) died 2–28 days afterwards.

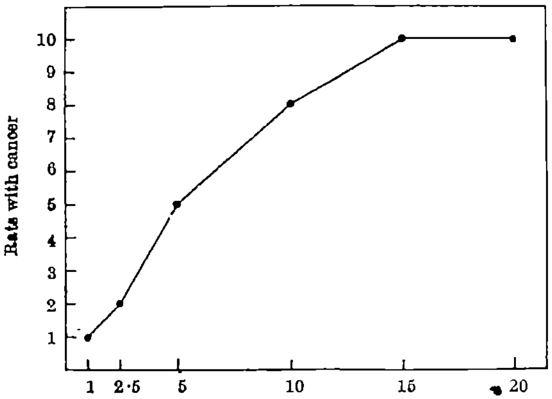

Fig. 2. Incidence of mammary cancer in groups of ten rats fed DMBA once only

It is known that the application of large amounts of 3-MC to the skin of mice causes leukopenia[10]. The leukocytes of the blood of rats were counted in quadruplicate before and at frequent intervals following a single feeding of DMBA (20 mgm.) to rats 50 days old. There was no change in their number for 24 hr., but leukopenia developed shortly thereafter and it was long-lasting (Fig. 3). The steady increase in body-weight of the young rats was interrupted for two days but growth recommenced thereafter (Fig. 3). But the sexual rhythm, demonstrated in the regular recurrence of œstrus cycles, was not delayed by feeding the carcinogen; œstrus appeared every 4·15 days both in DMBA-fed and in untreated control rats. It is clear that DMBA induced cancers and leukopenia and also caused a temporary cessation of body-growth, but brought about no significant decrease in the production of gonadotrophin by the hypophysis or in function of the ovary.

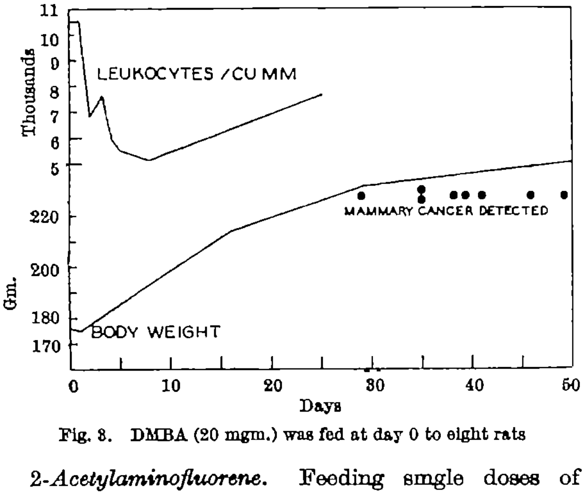

Fig. 3. DMBA (20 mgm.) was fed at day 0 to eight rats

2-*Acetylaminofluorene*. Feeding single doses of 2-AAF was a relatively inefficient method of inducing mammary cancer (Table 1). Twenty rats (50 days old) were fed an alcohol-containing solution of 2-AAF (50 or 100 mgm.) and six of them developed cancer of the breast within five months; no other tumours were observed. The chief interest of this compound was in its anæsthetic effects which were apparent after doses of 75–100 mgm. Due to its limited solubility in oil, 2-AAF was usually given in two divided doses separated by a 4-hr. interval. The rats became drowsy within 1 hr. after the first dose and were asleep within 2 hr. after the second feeding. They remained unconscious and did not move their position in the cage for 24 hr., but most of them woke within a few hours thereafter. Control rats fed sesame oil containing 10 per cent ethanol were not anæsthetized. Moreover, anæsthesia was induced in rats by feeding a dose of 75 mgm. of a solution of 2-AAF which contained no ethanol; for reasons of solubility the solution was administered at a temperature of 43°. Likewise, profound anæsthesia was induced by a single feeding of 2-aminofluorene (150 mgm.) dissolved in sesame oil, 3 ml., containing no ethanol.

Suppression of Mammary Cancer

At 50 days of age, normal female rats were fed a single dose of 3-MC (100 mgm.) and divided into groups. This feeding was the only experimental variable in the control rats which were maintained as virgins, and all developed mammary cancer (Table 2). Indeed, we have shown above that a single feeding of 3-MC (100 mgm.) induced mammary cancer without exception in normal female rats of this age, and that the tumours were demonstrated although not visible to the unaided eye after two weeks. Accordingly, at 65 days of age, the endocrine status of rats in many of the groups was modified drastically by breeding or by administration of steroid hormones.

The expected incidence of mammary cancer was lessened notably in rats bred 15 days after their solitary feeding (Table 2). Moreover, the daily injection of progesterone (4 mgm.) or of œstradiol-17β (10 μgm.) beginning at age 65 days, caused a similar decrease in the rate of incidence. The combined administration of progesterone (4 mgm.) with œstradiol-17β (1 or 10 μgm.) each day for 50 days induced the characteristic gestational type of hyperplasia of the mammary glands, which resembles that found in rats on day 15 of pregnancy, but few mammary cancers ever developed in these rats (Table 2); the neoplasms had been suppressed by the hormonal treatments.

In earlier work[11] the repeated feeding of 3-MC to rats at the onset of pregnancy, or to other animals

Table 2. SUPPRESSION OF MAMMARY CANCER IN PREGNANCY AND IN RATS INJECTED DAILY FOR 50 DAYS BEGINNING 15 DAYS AFTER A SINGLE INTRAGASTRIC INSTILLATION OF 3-MC (100 MGM.)

Steroids injected	No. with cancer	Appearance of palpable tumours (days)			Active centres
		range	median	mean	
None: normal female	10	46–84	56	58·3±11	1·6
None: pregnant	6	30–76	50	48·6±18	2·2
Progesterone (4 mgm.)	8	35–121	46	61·4±30	2·0
Œstradiol-17β (10 μgm.)	7	77–115	97	96·3±13	2·3
Progesterone (4 mgm.) and œstradiol-17β (10 μgm.)	2	42 and 121	—	—	1·0
Progesterone (4 mgm.) and œstradiol-17β (1 μgm.)	3	42–133	45	—	1·0
Progesterone (4 mgm.) and œstradiol-17β (0·01 μgm.)	8	36–120	43	51·9±28	3·2

There were 10 rats in each group and 3-MC (100 mgm.) was administered to every rat at age 50 days. All the animals were virgin females except one group which were bred between age 65 and 68 days; steroids were not administered to these groups. In the others, hormones dissolved in sesame oil (0·2 ml.), were injected intramuscularly 6 days each week for 50 days beginning at 65 days of age. The rats were observed for 150 days.

injected with large quantities of equine gonadotrophin[3], seldom induced mammary cancer. The present experiments demonstrate an effect of a different kind since they show that œstradiol with progesterone, while inciting brisk growth of normal mammary glands, often destroyed the young cancers induced within the previous two weeks by a large dose of 3-MC.

Discussion

Induction of cancer by a solitary feeding of polynuclear carcinogens emphasizes the high importance of the alimentary tract as a portal for their entry and, indeed, of a single meal for the development of mammary cancer in the rat. This method has advantages over multiple feeding in its extreme simplicity and in saving of labour and of rare or costly compounds associated with equal rapidity, and invariability of development of multiple mammary cancers. A stoichiometric relationship exists between the dose of effective carcinogens and the rate of incidence of the tumours, together with their number. The mammary cancers arise under highly restricted conditions, but these are easily fulfilled. All young adult female rats of the Sprague–Dawley strain fed an optimal amount of DMBA developed mammary cancer under the favourable hormonal conditions which prevail in them. Pregnancy, or the administration of progesterone with œstradiol, frequently destroyed many young cancers that were obtaining a foothold, and rats in this class never suffered a recrudescence of their mammary cancers.

Not all the cells of the body were injured by a single moderately large feeding of DMBA and lesions developed selectively. The hæmatopoietic and lymphatic systems were damaged and two types of cancer were induced, while the production of gonadotrophin by the hypophysis, and of phenolic œstrogens by the ovary, were undisturbed.

Not all the cells of the responding animals became malignant after feeding the effective polynuclear hydrocarbons; cancer developed only in the mamma and in special sebaceous glands, while sarcoma was never encountered. All the mammary cancers were adenocarcinomata and squamous carcinoma was not observed in the breast. Yet in companion rats the intramuscular injection of the effective carcinogens evoked sarcoma, locally, in most of them when these carcinogens were injected in muscle. The properties which endow special cells of the body with selective vulnerability to trace amounts of polynuclear hydrocarbons are unknown.

Not all the many millions of cells of the mammary glands became malignant after feeding effective amounts of the carcinogens. The maximal number of mammary cancers which has been observed in this laboratory after a single feeding is 21. A threshold response to the hyperconjugated hydrocarbons is involved in certain cells of the mammary gland in the induction of cancer of the breast by hydrocarbons, since a minimal effective dose gives rise to only one active centre.

Berenblum[12] has postulated that carcinogenesis develops in multiple independent stages. The present experiments demonstrate that mammary cancer, under the stated conditions, arises in a single step.

This work was aided by grants from the American Cancer Society and from the Jane Coffin Childs Memorial Fund for Medical Research.

TERMINOLOGY IN PLANT- AND SOIL-WATER RELATIONS

A RECENT article[1] under the above title seems unnecessarily complicated and in some respects misleading.

Consider the transfer of water, through a membrane permeable only to water, from a solution α at temperature T, at pressure P^{α}, and having concentration(s) m^{α} of solute(s), to a solution β at temperature T, at pressure P^{β}, and having concentration(s) m^{β} of solute(s). Water will pass spontaneously from solution α to solution β, *or* the two solutions are in equilibrium, *or* water will pass spontaneously from solution β to solution α, according as:

$$\mu_W(T,P^{\alpha},m^{\alpha}) - \mu_W(T,P^{\beta},m^{\beta}) \gtreqless 0 \qquad (1)$$

where $\mu_W(T,P,m)$ is the chemical potential of water in a solution at temperature T, at pressure P, and having concentration(s) m of solute(s). We now identify β with pure water at temperature T and at atmospheric pressure by putting $P^{\beta} = 1$ atm. and $m^{\beta} = 0$, and define a dimensionless number W called the 'water number' of the solution α (whether α is a solution in a beaker, a compressed solution in a turgid cell, soil-water surrounding the roots of a plant, or otherwise) by the relation:

$$W = \{\mu_W(T,P^{\alpha},m^{\alpha}) - \mu_W(T,1\text{ atm.},0)\}/RT \qquad (2)$$

where R is the gas constant. The water number W is then an exact thermodynamic discriminant determining according to its sign whether pure water will flow into (< 0), or out of (> 0), the solution α. Similarly water will flow from a solution with water number W_2 to a solution with water number W_1 if $W_2 > W_1$ and conversely. A solution with a negative water number 'wants' to gain water; a solution with a positive water number 'wants' to lose water.

In order to express the water number in terms of more familiar experimental quantities we begin by rewriting equation (2) in the form:

$$RTW = \{\mu_W(T,P^{\alpha},m^{\alpha}) - \mu_W(T,1\text{ atm.},m^{\alpha})\} + \{\mu_W(T,1\text{ atm.},m^{\alpha}) - \mu_W(T,1\text{ atm.},0)\} \qquad (3)$$

and then evaluate the two terms separately. With only trivial inaccuracy we then obtain the following set of thermodynamically equivalent relations ; which one is used, is entirely a matter of experimental convenience :

$$W = (P^{\alpha} - 1\ \text{atm.})V_{\text{W}}/RT + \ln (p_{\text{W}}/p^{\bullet}_{\text{W}}) \qquad (3a)$$

where V_{W} is the molar volume of water, p_{W} is the partial pressure of water over the solution, and $p^{\bullet}_{\text{W}}$ is the vapour pressure of pure water :

$$W = (P^{\alpha} - 1\ \text{atm.})V_{\text{W}}/RT - k_f \Delta T_f \qquad (3b)$$

where k_f is the cryoscopic constant of water and ΔT_f the lowering of the freezing point (equation 3*b* is, of course, restricted to 0° C.) :

$$W = (P^{\alpha} - 1\ \text{atm.})V_{\text{W}}/RT - k_{\text{b}} \Delta T_{\text{b}} \qquad (3c)$$

where k_{b} is the ebullioscopic constant of water and ΔT_{b} the elevation of the boiling point (equation 3*c* is, of course, restricted to 100° C.), and :

$$W = (P^{\alpha} - 1\ \text{atm.})V_{\text{W}}/RT - \Pi V_{\text{W}}/RT \qquad (3d)$$

where Π is the osmotic pressure of the solution.

Of the four methods of measuring the second term in equations (3) the third has in practice been used scarcely at all, while the first and second have been used much more often, and usually with much higher accuracy, than the fourth. Results obtained by any of these four methods are often expressed as osmotic coefficients φ in terms of which we have the alternative relation :

$$W = (P^{\alpha} - 1\ \text{atm.})V_{\text{W}}/RT - M_{\text{W}}\varphi m^{\alpha} \qquad (3e)$$

where M_{W} is the molar mass of water and m^{α} is the sum of the molalities of all the solutes in the solution. Tables of φ for solutions of common solutes (including sucrose) are available[2].

Equations (3*a*) to (3*e*) are thermodynamically equivalent. Equation (3*d*) can be rearranged in terms of quantities with the dimensions of pressure as follows :

$$-RTW/V_{\text{W}} = \Pi - (P^{\alpha} - 1\ \text{atm.})$$

or in terms of a few of the names commonly used by botanists: suction pressure (or diffusion pressure deficit) = osmotic pressure − wall pressure (or turgor pressure). In my opinion the apparent simplicity of this formulation, together with the traditional preoccupation of botanists with osmotic pressures to the neglect of more important ways of measuring essentially the same quantity, has led to a great deal of confusion, misunderstanding and pointless argument (as well as to the corruption of mechanical terms such as 'pressure', 'force', 'stress' and 'potential'). In particular, while the wall pressure is the actual excess pressure over 1 atm. in a more or less turgid cell, neither the suction pressure nor the osmotic pressure is an actual pressure in any part of a plant during its approach to equilibrium with its surroundings.

The definition of water number can easily be extended to systems where variables other than pressure and concentration are important. For example, if the difference of heights $h^{\alpha} - h^{\beta}$ is important (as in a tall tree) the gravitational term $M_{\text{W}}g(h^{\alpha} - h^{\beta})$ must be added to the left-hand side of equation (1).

Water numbers and indeed any thermodynamic treatment can, however, only be applied to a given system (for example, soil + plant + air) when the whole of that system is at one and the same temperature (cf. par. 6 of ref. 1, where the contrary is stated).

The application of water numbers to practical botany will be described more fully elsewhere.

DR. McGLASHAN's concept of 'water numbers' is an alternative step in the direction suggested by the delegates to the Unesco–Spain symposium on plant water relations in arid regions[1]. It, too, proposes a single term to replace the larger number at present in use and has simply and clearly partitioned this quantity into measurable components.

However, as a substitute for the proposals it does not encompass the identifiable components that may contribute to the 'water potential'. The symposium delegates felt that the additional factors which were recognizable should be given consistent names, whereas the use of 'water numbers' provides a name for the total potential only.

In general terms, the symposium delegates were keen to develop a terminology which would be more comprehensive than the existing plant water systems. To this extent, pressure, matrix and osmotic components were introduced, recognizing that, for example, the matrix term might not be necessary to evaluate the total water potential in plants or the osmotic component necessary to evaluate the total components in soils. It was also envisaged that other component potentials due to external force fields, such as gravity and electricity, could be included if necessary or desirable.

Dr. McGlashan's proposal of 'water numbers' is identical with our 'water potential' (that is, the difference in the Gibbs function for the single component, water, in a multiple component system and the same component in the reference state). He does not provide for naming the several factors that contribute to the overall water potential as we have done. His equations 3*a*–3*e* are equivalent relations expressed in terms of various methods that might be used to evaluate the chemical potential under standard laboratory conditions. These equations all represent standard methods for evaluating the chemical potential of water in pure systems.

Methods based on evaluation of the freezing or boiling point of water are subject to errors of unknown magnitude since they assume that the entropy and enthalpy of the water in system behave the same as those of pure free water. This is known to be incorrect at least for soil water[2], so that the values determined by these methods can be applied, without error, only at the freezing and boiling temperatures.

The application of the classical Gibbs function (and hence the water number) to systems that are not at constant temperature is not possible because flow of heat occurs whenever there are temperature differences. This upsets the equilibrium conditions, thus invalidating the equilibrium thermodynamics. This is also true in any system in which any kind of flow is taking place. It is still possible, however, to use thermodynamic concepts and terminology for non-equilibrium systems, if the change in entropy of the system is considered[3]. The terminology proposed by the delegates to the Unesco–Spain symposium is adaptable to applications of thermodynamics to irreversible processes, hence temperature differences may be included in the terminology. Likewise, the water potential (or water number) determined on a system in equilibrium at one temperature will be different from the water potential of the entire system in equilibrium at another temperature, therefore it is necessary to consider a temperature (and hence an entropy) contribution to the water potential.

It might be mentioned that at the request of the symposium delegates, we also circulated the proposals to a large number of scientists known to be interested in the subject of terminology in plant–soil–water systems. The range of response varied from complete rejection to complete acceptance, with most correspondents being in favour of general acceptance with some modifications. In general, most scientists concerned with either soil- or plant–water relations alone considered that either the existing terminologies were satisfactory, or that the new proposals compromised the existing ones to a degree that was not of benefit. The majority of scientists concerned with the interacting plant–soil–water system were, on the other hand, keen to have a more unified form of expression. These varied opinions have been summarized, and the original proposals modified to include as many of the comments as possible. The resultant document will be published shortly by Unesco, in the Proceedings of the Madrid symposium.

The original proposals were also discussed at the recent congress of the International Soil Science Society at Madison, Wisconsin. Here again a wide range of response was encountered, and Commission I (Soil Physics) of the International Society of Soil Science has appointed a committee to investigate the subject of soil water terminology.

RADIAL PARTICLE DISPLACEMENTS IN POISEUILLE FLOW OF SUSPENSIONS

By DR. G. SEGRÉ
Cartiera Vita Mayer and Co., Milan
AND
DR. A. SILBERBERG
Weizmann Institute of Science, Rehovot, Israel

WE have observed that macroscopic spherical particles collect into a thin, annular region when an initially uniform dilute suspension is passed in laminar flow through a straight tube. The development of the effect is proportional to the length l of the tube, to the mean velocity V of flow and to the fourth power of the ratio of particle radius a to tube radius R.

Our equipment consisted of the flow apparatus, an optical scanning device and an electronic counting circuit. Spheres of polymethyl methacrylate, in various uniform fractions of diameters between 0·8 and 1·6 mm., were suspended in a liquid of the same density $\rho = 1{\cdot}18$ gm./c.c. and of high viscosity $\eta = 400$ cp.). The flow apparatus consisted of a vertical tube of variable length, diameter 11·6 mm., terminating in two containers with the necessary stirrers and pressure-head regulators. At a selected cross-section of the tube, two narrow mutally perpendicular light rays could be made to traverse it without distortion and thus to determine a precisely selected small region at their crossing. Two photocells and a coincidence circuit permitted the computation of the actual number of particles which passed the point of intersection. From this number the average concentration of the suspension, as a function of the distance from the axis of the tube, could be calculated by dividing by the local velocity of flow.

The results are symmetrical about the axis, and are independent of the shape of the mouth of the tube. At very low velocities of flow, or at small distances from the input end, the particle count follows a parabolic distribution, showing that the concentration is constant over the entire cross-section (curve 1, Fig. 1).

At cross-sections farther down the tube, distributions of the type shown in curves 2 and 3, Fig. 1, are observed. In terms of particle concentrations (assuming the same parabolic velocity distribution as at the mouth) the results conform to the 'tubular pinch' effect illustrated in Fig. 2.

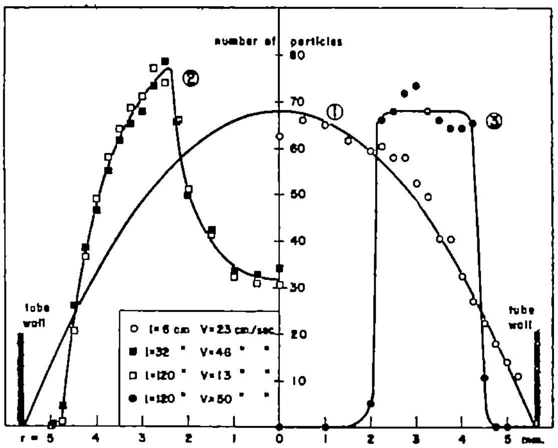

Fig. 1. Number of particle passages as a function of radial position in tube for a given total throughput (uncorrected for finite scanning cross-section). Particle radius 0·8 mm., initial concentration 1 part./cm.^{3}

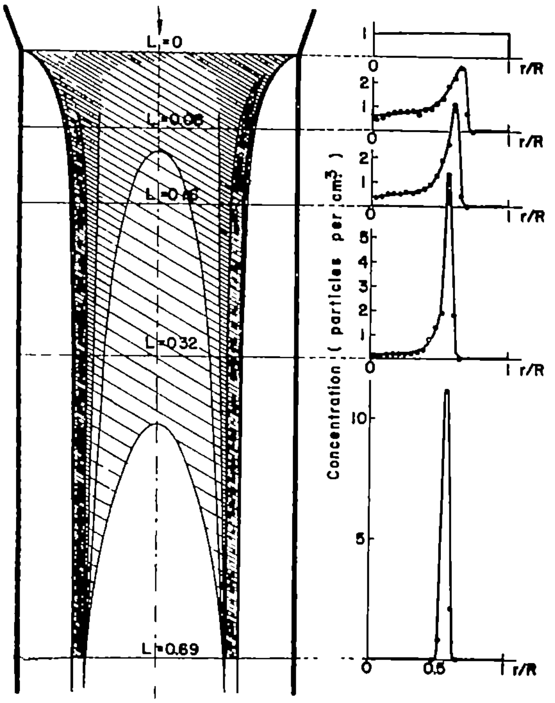

Fig. 2. The 'tubular pinch' effect: particle concentration as a function of radial and longitudinal position in tube. Initial concentration 1 part./cm.³. Concentrations are indicated by shading; closest shading (more than 2 part./cm.³); next (1–2 part./cm.³); next (0 5–1 part./cm.³); lightest shading (0–0 5 part./cm.³)

The results in Fig. 2 are plotted in terms of a reduced tube radius (r/R) and tube length:

$$L = (a/R)(av\rho/\eta)(l/R)$$

where $v = (a/R)^2V$, and $(av\rho/\eta)$ can be defined as a relative particle Reynolds number[1]. All our results can be superimposed when plotted in these coordinates, that is, the same particle distributions are reached at corresponding positions L in the tube. The dependence of L on the relative particle Reynolds number, or more explicitly on the product Vl, can be shown to imply a radial particle velocity proportional to V^2. The force responsible for the effect thus originates in the inertia of the fluid.

Particle re-arrangements in parabolic flow have been suspected in the past, and certain anomalous flow-behaviour of suspensions has been explained in this way. Causes other than inertia forces have, however, been made primarily responsible as no direct observations of particle movements were made. Deviations from the Einstein viscosity equation (sigma effect) were explained by wall effects[2] and the criterion of minimum energy dissipation[3].

Some direct observations of particles concentrating in the central region of the tube[4] have been reported, but the relevant experiments seem to be of low precision or may have been complicated by electrostatic and other phenomena, as, for example, in the case[5] often quoted of red cells moving into the axis of blood capillaries.

On the theoretical side, the effects of fluid inertia have almost always been neglected in view of the difficulty of solving the complete Navier-Stokes equations of motion. Cases such as ours are thus explicitly excluded from available analyses of tube flow. The only way in which quadratic terms have been allowed for in a few cases[6,7] is through the inclusion by postulation of a transverse force which, as in the 'Magnus effect', arises from the combination of a rotatory and a translatory motion relative to the undisturbed flow of the fluid. It can be shown[8] by solving the linearized equations of motion that a spherical particle carried along by an unbounded parabolic field of flow is subjected to a couple and to a longitudinal force which give rise to a rotation and a translation, each proportional to the mean velocity of flow. Adopting the formalism of the Magnus effect, one can substitute these velocities in the Kutta–Jukowsky formula and obtain a force:

$$f = -k(a^5V^2r\rho/R^4)$$

and a radial velocity $\dot{r}$ corresponding to this force:

$$\dot{r} = -(k/6\pi)(a/R)^4(V^2\rho r/\eta)$$

proportional to V^2, as observed, but directed inwards only. In our case the radial force acting on the spheres is centripetal at the wall but centrifugal at the centre. A stationary distribution is thus reached, and the value of (r/R) where the particles concentrate seems to be independent of all other variables.

It is worth noting that if we assume for the dimensionless coefficient k the value suggested by Tollert[7] or that calculated by Saffman[6], agreement in order of magnitude with the observed centripetal removal of a particle from the wall is obtained.

This approach does not explain the strange dependence of the force on the distance from the centre with its reversal of sign. The curvature of the field of flow is patently insufficient to account for this behaviour. It is in the presence of a rigid wall at $r = R$ that the explanation must be sought. It should be noted that symmetry requirements are satisfied, as a force proportional to r, and thus, vanishing at the centre, is consistent with the observed removal of particles in the vicinity of the tube axis. On the other hand, the criterion of minimum energy dissipation according to which one would expect the particles to congregate in the centre is contravened.

The results exemplified by Fig. 1 are independent of the overall particle concentration up to the largest volume fraction (0·4 per cent) used by us, and a linear superposition of the effect is observed when particles of two different sizes are examined simultaneously. The points represent averages involving at least 20 separate experiments and the scatter shown in the diagrams is representative of the precision obtained.

The effect may be important in explaining certain anomalous flow behaviour of suspensions and may find application in the fractionation of particles of different size.

To the best of our knowledge the centrifugal effect has not previously been observed nor are any theoretical predictions extant. The investigation is being pursued, and a full report will be published elsewhere.

Acknowledgements are due to Prof. A. Katchalsky for many valuable discussions and to Cartiera Vita Mayer and Co., Milan, for enabling one of us (G. Segré) to carry out this investigation at the Weizmann Institute.

Glass Formation in Solutions of Hydrogen Peroxide–Water and Deuterium Peroxide–Heavy Water

We have found that if a hydrogen peroxide–water solution, of suitable concentration, is put into a tube and frozen extremely quickly by plunging the tube into a Dewar flask containing liquid oxygen (90° K.), a transparent colourless solid is formed. This solid has the properties of a glass, in that it is both transparent and amorphous. A glass is also formed if the hydrogen peroxide solution is allowed to fall as drops on to liquid oxygen.

The hydrogen peroxide used was high-test unstabilized hydrogen peroxide from Laporte Chemicals, Ltd. The various concentrations were made, either by mixing the standard concentrations supplied by Laporte or by dilution of approximately 95 per cent w/w hydrogen peroxide with laboratory-distilled water. No attempt was made to de-gas the solutions. When necessary, the hydrogen peroxide concentrations were checked by potassium permanganate titrations, and these were accurate to 1 per cent.

The most convenient method of testing whether a given concentration forms a glass or not was found to be that described by Livingston and Zeldes[1]. The liquid solution at room temperature was allowed to fall as drops, of 2–5 mm. diameter, on to the surface of liquid oxygen. Initially, the drop floated on the surface of the liquid and froze to form a sphere. For concentrations 45·5–87 per cent w/w, perfectly transparent glass spheres were formed; for all other concentrations, opaque white spheres were formed, and these were presumably polycrystalline.

A glass is again obtained when hydrogen peroxide, of 45·5–87 per cent w/w, is put into a glass tube, on to an aluminium plate or between glass plates and then frozen in liquid oxygen. The glass now, however, has very marked cracks. The formation of cracks is presumably due to thermal contraction. No cracks were found in the case of the spheres, since there are no constraining walls on the sample. For all samples the glass is completely stable and no transformations were found on storing at 90° K. for two days.

The boundary at 45·5 per cent w/w between the concentrations which produce polycrystalline material and those which produce a glass is very sharp and corresponds to the eutectic point (Banfield, R. H., private communication) at 45·3 per cent w/w. The boundary at 87 per cent w/w is far less marked and can vary by ± 5 per cent w/w; this concentration is well above the second eutectic point (Banfield, R. H., private communication) of 60·5 per cent w/w, but it coincides, however, with a well-marked change in the slope of the melting point/concentration curve for hydrogen peroxide–water solutions as determined by Giguère and Maass[2] and by Kubaschewski and Weber[3] from measurements on quickly frozen (non-equilibrium) solutions.

Cooper and Watkinson[4] made measurements on the supercooling of hydrogen peroxide–water solutions, using slow cooling. They found supercooling for concentrations between 50 per cent w/w and 97 per cent w/w (the highest concentration used); at 86 per cent w/w they recorded the lowest freezing temperature for supercooled liquid. Cooper and Watkinson also reported the formation of a glass at 86 per cent w/w, when the sample at 194·5° K. was transferred to liquid nitrogen (77° K.). Bolz, Mauer and Peiser[5] performed X-ray diffraction studies on 90–95 per cent w/w hydrogen peroxide (Mauer, F. A., private communication) condensed from the vapour at 77° K. For temperatures below 92° K. they found an amorphous glass giving very broad (8°) diffraction lines.

We have also studied the effect of warming the glass samples. The solution to be tested was put into a small test-tube holding about 5 ml. of solution. A thermocouple was put into the centre of the solution and the whole assembly plunged into liquid oxygen; a glass was formed with some cracks. The leads of the thermocouple were connected to a potentiometric pen recorder of 1 sec. response-time. The accuracy of temperature measurement was ± 2° K. The tube was removed from the liquid oxygen and was placed in the air at room temperature. A typical warming curve is shown in Fig. 1 for 61·0 per cent w/w hydrogen peroxide. The quick rise of temperature *AB* is associated with the appearance of opacity in the sample which spreads along the tube, and this is presumably due to exothermic crystallization of the solution. Several measurements were made on 61·0 per cent w/w samples, and for these it was found that crystallization occurred at 165 ± 6° K. Similar behaviour was found by Bolz, Mauer and Peiser[5], the crystallization for 90–95 per cent w/w hydrogen peroxide, however, commencing at 92° K. The region over which the temperature remains constant, *CD* in Fig. 1, is due to melting of the crystals and was found to be at 217 ± 2° K. This is in agreement

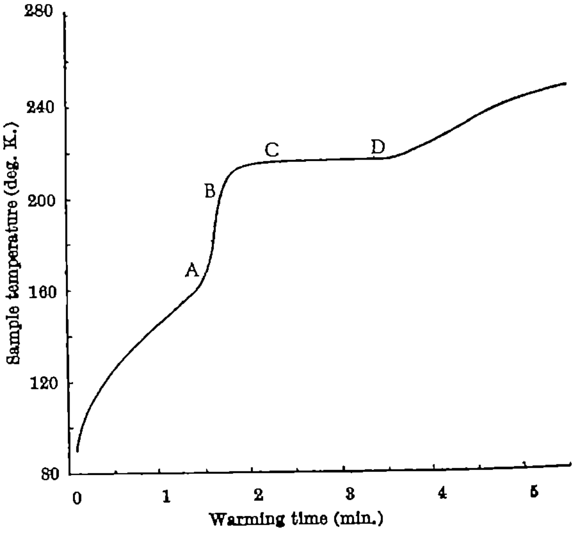

Fig. 1. Warming curve for 61·0 per cent w/w hydrogen peroxide

with measurements of the melting points by Giguère and Maass[2], and by Kubaschewski and Weber[3]. We have tested two other concentrations, 45·5 per cent w/w and 80 per cent w/w and these showed a similar behaviour, crystallization taking place at 141 ± 10° K. and 157 ± 10° K. respectively. The melting points of these two concentrations were found to be 222 ± 5° K. and 215 ± 5° K., in agreement with published measurements[2,3]. In all the glass samples the cracks annealed out between 130 and 155° K., that is, before the crystallization took place.

Tests of glass formation were also made using deuterium peroxide, obtained from Laval University. The concentration used was 80 per cent w/w, with 99 per cent deuterium. It was found that a stable glass was produced as above, both in spheres and in a glass tube. Giguère and Secco[6] have also reported the formation of glasses in deuterium peroxide, but on storing in liquid air for 10 min. they found a spontaneous conversion to crystallization. We have not found this effect and cannot explain the difference between the two results.

These observations were obtained during experiments involving ultra-violet irradiation of hydrogen peroxide–water solutions at 90° K. for electron spin resonance spectroscopy[7].

The potassium permanganate titrations were performed by Mr. J. M. Richards of this Department. We wish to acknowledge helpful discussions with Mr. R. H. Banfield of Laporte Chemicals, Ltd., and, in particular, for his suggestion of an examination of the eutectic mixtures. The hydrogen peroxide for these measurements was kindly supplied by Laporte Chemicals, Ltd. The deuterium peroxide was given to us by Prof. P. A. Giguère of Laval University, Quebec. This work was supported by the British Empire Cancer Campaign, for the assistance of which we express grateful thanks.

A Spectrometer for the Far Infra-red

A SPECTROMETER based on a Fresnel zone plate as the focusing and dispersing element has been constructed for use with infra-red radiation between 35μ and 80μ.

The instrument is intrinsically simple. A heated nichrome coil and a Fresnel zone plate are mounted on opposite ends of a 4-m. *I*-beam so that the zone plate produces a series of monochromatic images of the source disposed along the axis of the instrument. A bolometer detector mounted on a carriage moves along a straight track attached to the *I*-beam so as to scan the spectrum. A light chopper in front of the source uses alternating open holes and potassium bromide windows to eliminate virtually all but first-order spectra from the signal. The sample cell is located in the light path close to the source.

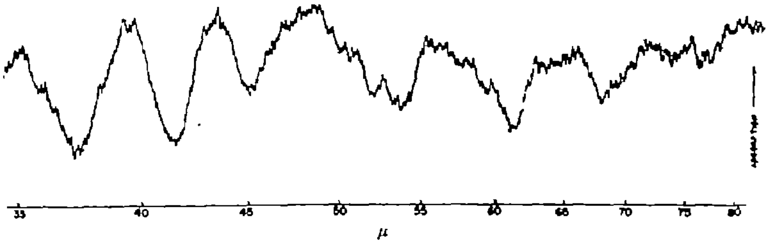

Fig. 1

The zone plate is of the reflecting type, containing 234 half-wave Fresnel zones. The surfaces of the even-numbered zones are raised 12·5μ above those of the odd-numbered zones to give a maximum optical efficiency at 50μ. The zone radii are calculated to make the system free from spherical aberration at 68μ and to give the zone plate a focal length of 73·5 cm. at that wave-length.

The zone plate focuses a monochromatic image of the source directly on the bolometer element with no intervening collimating mirrors, or movable slits, as in a grating spectrometer. The simplicity of this design leads to ease of construction and good light-gathering power. Fig. 1 shows the absorption spectrum of atmospheric water vapour.

Patents have been applied for.

Elimination of a Glow Discharge in an Induction-heated Vacuum Furnace

RECENTLY, J. P. Burden[1] discussed the elimination of a glow discharge in induction-heated vacuum furnaces. As Burden indicated, the glow discharge is troublesome because it robs energy. In addition, in vacuum analysis systems, the discharge is often intolerable because of the consequent evolution of gases from glass furnace parts.

For the past three years, an almost perfect method of eliminating the glow discharge has been employed in this Laboratory. It was found that a small horseshoe permanent magnet placed near the glass furnace wall prevents the initiation of a discharge, or immediately quenches a discharge once started. The exact position of the magnet varies slightly, and must be determined empirically, but is about one centimetre or less from the furnace wall. The system to which the magnet 'trick' has been applied is a conventional vacuum fusion analysis apparatus with an all-glass, air-cooled furnace[2] inductively heated by a 2·5-kW., 500-kc. oscillator. The idea of using a magnet in the manner indicated was suggested by the common application of a permanent magnet as an 'ion trap' on television picture tubes.

Strangely enough, the use of the magnet has twice been observed to have the opposite of the desired effect. That is, a glow discharge was initiated when the magnet was brought near the furnace, and extinguished on removal of the magnet.

No attempt will here be made to suggest how the magnet succeeds (or rarely, does not succeed) in eliminating a glow discharge. Suffice it to say that the success has been just short of perfection, and the more gratifying because it was attained at little expense and much convenience.

Visible Twist on Sodium Chloride Whiskers

IT is well known from Eshelby's[1] work that a whisker containing an axial screw dislocation will have the form of a twisted rod. Sodium chloride whiskers have been grown in which such a twist was quite visible to the naked eye.

The whiskers were prepared by a modification of Evans's method[2]. A small sodium chloride crystal grown from the melt was placed in a solution of sodium chloride, containing a small amount of polyvinyl alcohol. The whiskers grew on this seed-crystal. The mean length of the whiskers was 150 mm., their thickness 1–30μ and they were rectangular in cross-section. Some of the whiskers, mainly the thinner ones, were spiral. The twisted form was easily visible to the naked eye: with suitable light brighter and darker spots became visible along the lengths of whiskers, because due to their twisted form only some parts of them reflected the light. The distances between light spots on most of the crystals were 1–40 mm. and they were uniformly distributed along the length of the whiskers. It is suggested that this is probably a twist described by Eshelby. He gives the formula for the twist per unit length as follows:

$$\text{twist } \alpha = k \times \frac{\text{Burgers vector } b}{\text{area of whisker cross-section } A}$$

where k is a constant depending on the shape of the cross-section. The Burgers vector of the screw dislocation calculated with this formula results in values of 60–240 Å. These are the results of measurements carried out on twelve whiskers. Webb[3] obtained similar results among others by the X-ray diffraction method.

In our opinion, polyvinyl alcohol plays little part in the production of whiskers, because Gyulai[4] also found spiral whiskers in aqueous solution of potassium bromide containing no polyvinyl alcohol. The whiskers were tested by twisting. Fig. 1*a* shows a spiral whisker having eleven light-spots. The same whisker is shown in Fig. 1*b*, twisted outwards through 360°. It can be seen that the number of light-spots has diminished by four. Twisting further through 360°, the number of light-spots diminished to three (Fig. 1*c*). Twisting the whisker through 990°, it became quite smooth, and light-spots were no longer visible (Fig. 1*d*). If one end is cut the whisker twists back again. After this twisting-out the twisting-back phenomenon was observed in each test. In most cases the whisker was almost completely twisted back. It appears that this phenomenon disagrees with Eshelby's suggestion, according to which after a certain twisting the dislocation leaves the whisker. There may be several explanations.

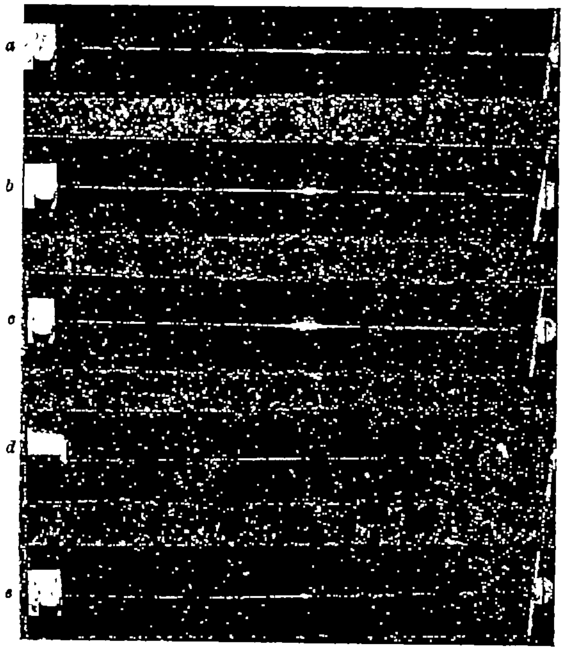

Fig. 1. *a*, Naturally twisted sodium chloride whisker (original length); *b*, the same whisker twisted through 360°; *c*, the same whisker twisted through 720°; *d*, the same whisker twisted through 990°; *e*, the same whisker, one of its ends cut off after twisting, and the whisker quite twisted back

Further investigations on whiskers are in progress. A detailed paper will be published in *Acta Physica Hungarica*.

We wish to thank Prof. Z. Gyulai for valuable discussion and interest.

Weissenberg Effect in the Thick White of the Hen's Egg

WHEN a vertical rod is rotated in certain liquids, the liquid climbs up the rod. This phenomenon was apparently first observed by Weissenberg and Russell[1], and in 1949 Reiner, Scott Blair and Hawley[2] suggested that it be described as the 'Weissenberg effect'.

Its theory is not clear and has been discussed by Garner and Nissan[3], Rivlin[4], Reiner *et al.*[3] and Roberts[5]. The effect occurs only rarely and has been observed in highly viscous solutions of rubber in benzene[3], certain soaps in hydrocarbon solvents[3], over-aged sweetened condensed milk[2] and certain types of dilatant honey[6].

During an investigation into the rheological behaviour of cake batters it was found that most of them exhibited the Weissenberg effect to a greater or lesser extent dependent on their egg content. When the separate constituents of egg were tested it was apparent that the more viscous component of the albumen, the so-called thick white[7], sometimes also referred to as the middle dense layer or albuminous sac[8], exhibited the Weissenberg effect most markedly. This material was readily isolated by a method virtually identical with that of Brooks and Hale[7]. The eggs were broken individually on a clean B.S. 14 mesh sieve which had been wetted with water and the outer thin white was allowed to drain off. After tilting the sieve gently to and fro for 1 min., the white around the yolk was cut and the yolk removed by hand. After draining off the inner thin white, the thick white remained on the sieve and could be used for the test.

The thick white of the hen's egg thus provides an easily accessible material by means of which the Weissenberg effect may be demonstrated.

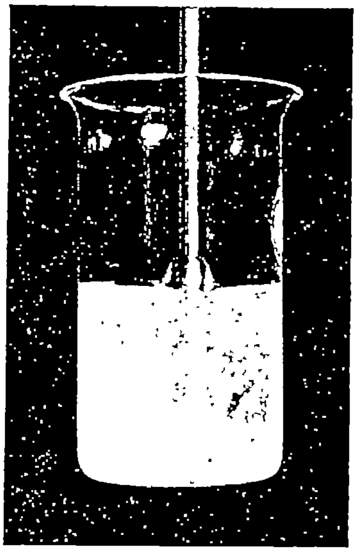

Fig. 1

I wish to thank Mr. A. W. Hartley for Fig. 1, which shows the Weissenberg effect in the thick white.

GEOPHYSICS

Lunar Tide in the F_2 Layer of the Ionosphere near the Geomagnetic Equator

It is well known that the maximum in the lunar tide variation of f_0F_2 occurs at about 10 lunar hours at moderate geomagnetic latitudes and at about 04 lunar hours near the geomagnetic equator[1,2]. Recent analyses of the lunar variations at Singapore, Ibadan and Bombay have indicated non-agreement in the phases of the variation at stations having the same geomagnetic latitudes.

In this communication the analysis of lunar variations of f_0F_2 at Leopoldville for the period of three years from November 1953 to October 1956 is presented. From the published hourly values of f_0F_2, daily averages of three-hourly values between 11 hr. to 13 hr. (15° E.M.T.) are computed and are referred to as midday values. The 27-day running averages of these values are computed and are subtracted from the individual day values for the central day of the respective 27-day period to obtain the deviation of f_0F_2 for that day. The deviations of f_0F_2 for days having the same phase (μ) of the Moon are then grouped together, and thus 24 such groups are obtained for the different phases of the Moon. The average deviations of f_0F_2 for each phase are computed separately for the months of southern solstice (November, December, January and February), for equinoxes (March, April, September and October), for the northern solstice (May, June, July and August) as well as for the whole year. To avoid the effects of

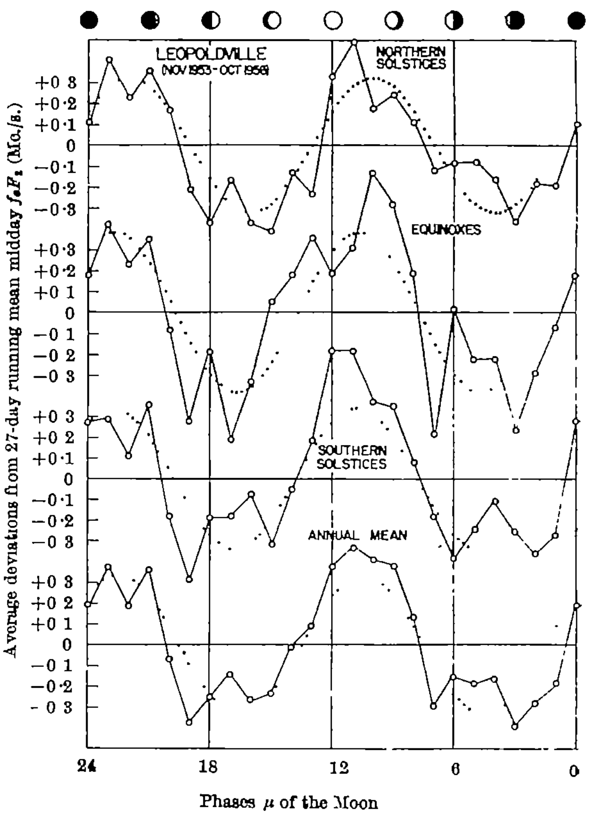

Fig. 1

Table 1. AMPLITUDE P_1 AND PHASE t_1 OF THE LUNAR VARIATION OF NOON f_0F_2 AT LOW LATITUDE STATIONS

Station	Geomagnetic latitude	Magnetic latitude	P_1 (Mc./s.)	t_1 lunar hour	Reference
Huancayo	0·6° S.	0°	0·45	4·0	1
Leyte	0·2° S.	3° N.	0·53	4·2	1
Tiruchy	1° N.	2·5° N.	0·18	2·8	1
Christmas Islands	2·1° N.	2·5° N.	0·33	4·7	1
Madras	3·1° N.	5·5° N.	0·14	3·8	2
Ibadan	10·4° N.	2·5° S.	0·38	3·3	4
Singapore	10·0° S.	8° S.	(0·30)	(4·0)	3
Leopoldville	3·1° S.	19° S.	0·33	10·5	this communication
Bombay	9·8° N.	12·5° N	0·24	10·0	2
Ahmedabad	13·6° N.	18·6° N.	0·35	10·2	2
Trinidad	22° N.	28·5° N.	0·31	9·2	1
Maui	20·9° N.	21·5° N.	0·36	9·1	1

the magnetic disturbances, the days with A_p value greater than 50 were excluded in averaging. Further, to reduce the scatter, the deviations exceeding more than 20 per cent of the corresponding 27-day mean value were also excluded. These eliminated only less than 9 per cent of the total number of available values. The result of the analysis is shown in Fig. 1. It may be mentioned that from one day to the next μ decreases by 0·81272, and the lunar time corresponding to a phase μ is given by $\mu \pm 12$ (lunar hours).

In Table 1 are compared the amplitudes and phases of the lunar variations of f_0F_2 at Leopoldville and at a number of low-latitude stations in the world. It is seen that the lunar variation at Leopoldville (geom. lat. $\Phi = 3{\cdot}1°$ S.) is completely out of phase with that at Madras ($\Phi = 3{\cdot}1°$ N.) or at any other equatorial station. The phase of the lunar variation at Leopoldville (magn. lat. = 19° S.) is very nearly the same as that at Ahmedabad (magn. lat. = 19° N.) having the same magnetic latitude. This suggests that the stations having the same magnetic latitude rather than the same geomagnetic latitude experience similar variation of f_0F_2. The equatorial type of lunar variation at Ibadan and the middle latitude type of variation at Bombay in spite of the geomagnetic latitudes of both stations being about 10° can be understood if one considers that the magnetic latitudes of the stations are about 3° S. and 13° N. respectively. The reversal of phase of the lunar tide in f_0F_2 takes place around magnetic latitude 10° or at magnetic dip 20°.

Spread-*F* and the Latitude Variation of Occurrence of Whistlers

RECENT work of whistling atmospherics has suggested that the incidence of the phenomenon is dependent on latitude. Crouchley[1], using data from Australian and Japanese stations, demonstrated that whistler activity reaches a maximum at about 45° geomagnetic latitude, while the Stanford group[2] report a maximum of occurrence at 50° geomagnetic latitude. In both these reports a marked decrease in activity at lower and higher latitudes is noted. The decreasing incidence at higher latitudes has been attributed[3] to decreasing thunderstorm activity, and rapidly increasing path-length and absorption with increasing latitude. However, the fall-off in activity at low latitudes cannot be so explained. Smith, Helliwell and Yabroff[3] have suggested an explanation of this low-latitude fall-off in terms of whistler propagation within field-aligned ducts. They showed that the necessary ionization enhancement within the ducts for *F*-layer heights falls off markedly with increasing latitude and argue, therefore, that this suggests that whistler occurrence should increase with latitude, since large enhancements would be expected to occur less frequently than small enhancements. It is the purpose of this communication to examine this point in more detail.

The frequency-spreading component of spread-*F* has been interpreted[4,5] as being due to the availability of a range of values of $N_{\max.}$ at the maximum of the F_2 layer; this range of values is thought to correspond to a system of irregularities each involving an enhancement (or a deficiency) of electron density relative to the background ionization. For any particular occurrence of frequency-spreading it is possible, in terms of this hypothesis and assuming critical reflexion conditions to apply, to calculate the ionization enhancement ($\Delta N/N$) required. It is now suggested that these postulated irregularities in the F_2-layer are, in fact, the lower extremities of the whistler ducts. If this is the case, then estimates of the electron density enhancements obtained from frequency-spreading information should support the contention of Smith *et al.* outlined above.

In work to be published elsewhere I have been able to fix limits to the range of values of ΔN observed at seven stations spread in geomagnetic latitude. Combining this information for a typical winter month with the monthly median critical frequency, it has been possible to produce, as shown in Fig. 1, a diagrammatic representation (shaded strip) of how the range of values of $\Delta N/N$ varies with geomagnetic latitude. (The position of that portion of the shaded strip bounded by dashed lines is less certain than

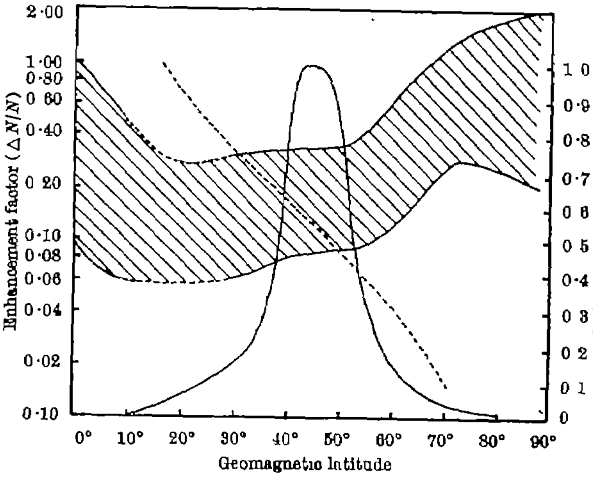

Fig. 1. Observed irregularity of electron density enhancement factors (shaded area) compared with the minimum required for whistler duct propagation (dashed curve) and with whistler occurrence data (full-line curve) for a range of geomagnetic latitudes

elsewhere because of the low incidence of frequency spreading at these latitudes.) Also shown in Fig. 1 is the graph of minimum $\Delta N/N$ against geomagnetic latitude (dashed curve) due to Smith *et al.* and Crouchley's latitude distribution of whistler occurrence. (Since whistler activity is most pronounced in the winter months the latitude distribution of whistler activity is largely dependent upon winter conditions.) It will be noted that for latitudes less than about 30° the observed range of $\Delta N/N$ involves values considerably less than the values required by Smith *et al.* and that this corresponds to the region of low whistler occurrence. At 32° the largest observed value of $\Delta N/N$ corresponds to the minimum required for whistler propagation, while above 50° all the observed values of $\Delta N/N$ are of sufficient magnitude to support whistler propagation. The 30–50° latitude region corresponds to that in which the whistler activity increases. It seems, therefore, that the explanation of the latitude variation of whistler activity based on propagation within field-aligned ducts is consistent with ideas at present being used to interpret the frequency-spreading component of spread-*F*.

I am indebted to Mr. J. Crouchley and Dr. J. A. Thomas for their interest and helpful discussion.

METALLURGY

Micropitting of Titanium during Anodic Oxidation in Formic Acid

The anodic oxidation of titanium in the majority of electrolytes (sulphuric, phosphoric, boric acid, etc.) results in the formation of a thin homogeneous dielectric oxide film of titanium dioxide (amorphous or crystalline). At constant current the potential increases with increasing film thickness, and, if the potential is then maintained constant, the ionic current decreases rapidly and the current becomes almost entirely electronic. In these circumstances, providing film breakdown does not occur, film growth practically ceases and oxygen evolution becomes the predominant electrode process.

In chloride electrolytes, however, film growth proceeds up to a potential of ~ 12–14 V., and if the potential is increased above this value film breakdown occurs, and titanium ions pass into the electrolyte, and are then precipitated as titanium dioxide. Corrosion of the titanium is confined to a relatively few, widely dispersed, small areas of the metal surface with the consequent formation of gross pits while the rest of the surface, which is coated with the initially formed anodic oxide, remains passive.

During a study of the anodic oxidation of titanium in various electrolytes it has been found that formic acid (and formates) gives rise to a phenomenon which does not appear to have been reported previously. Within a certain range of temperature and concentration of formic acid (Fig. 1, zone *C*) film formation, at constant current, proceeds up to a voltage of ~ 60 V., but as the potential increases above this value, very fine pits are formed uniformly over the metal surface (micropitting) and simultaneously titanium oxide is precipitated from the electrolyte. The potential slowly increases to ~ 120 V., indicating film growth, and then remains practically constant, and if anodizing is continued the pits are propagated into the metal to a considerable depth (Fig. 2). A microscopical examination of the metal surface during the initial stages of micropitting has revealed that different areas on the metal surface have different interference colours showing that the thickness of the surface oxide is not uniform.

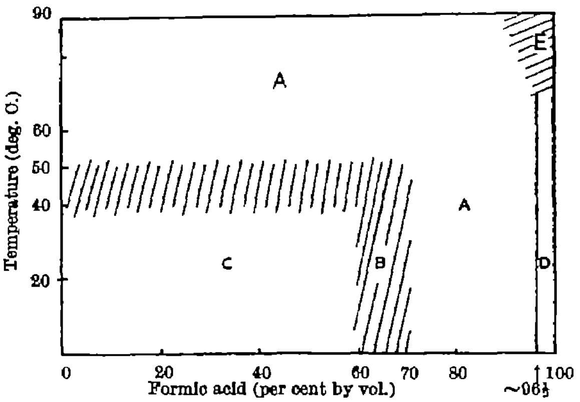

Fig. 1. Effect of concentration and temperature on the anodic behaviour of titanium in formic acid. *A*, Homogeneous dielectric oxide films; *B*, transition zone where homogeneous films show evidence of micropitting; *C*, micropitting; *D*, thick yellow non-adherent oxide films; *E*, transition zone between *A* and *D*

If, however, the temperature of the electrolyte is greater than ~ 50° C. or if the concentration is in the range of ~ 70–96 per cent by vol. formic acid (Fig. 1, zone *A*) micropitting does not occur and a homogeneous dielectric oxide film is formed. It should be observed that at 25° C., at a concentration of ~ 96 per cent formic acid, film formation can proceed to 400 V. without film breakdown, whereas in boric acid the maximum formation voltage is only ~ 250 V.

In region *D*, at very high concentrations of formic acid (~ 96·5 per cent to concentrated), a thick

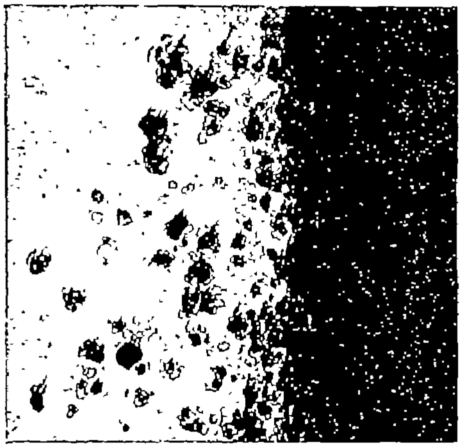

Fig. 2. Section of a micropitted specimen produced using 1 per cent by vol. formic acid, 25° C., 5 m.amp./cm.^{2} for 4 hr. (× *c*. 66). The section has been cut at 5° to the surface to exaggerate depth of penetration of pits. Depth of penetration, $4 \cdot 5 \times 10^{-3}$ cm.

dark-yellow, non-adherent oxide forms on the metal surface.

A consideration of data[1] on the rate of corrosion in different concentrations of formic acid at 35° C. reveals that zone *C* corresponds to the range of concentration where the corrosion-rate is high and region *A* where the corrosion-rate is at a minimum.

It is apparent that the mechanism of micropitting is highly complex, as the electrode processes which occur involve the anodic oxidation of titanium, localized corrosion of titanium, oxidation of formic acid to carbon monoxide and dioxide and oxidation of hydroxyl to oxygen. The heterogeneity of the metal and adsorption of formic acid on active centres[2,3] and the formation of complexes between titanium and formic acid may also contribute to the overall process.

The reason for the formation of barrier films at more elevated temperatures and at higher acid concentrations (Fig. 1, zone *A*) may involve a consideration of the kinetics of oxidation of formic acid and the properties of the anodic oxide film under the conditions specified.

The phenomenon of micropitting appears to be confined to the titanium–formic acid system as similar results could not be achieved with niobium or zirconium.

It is considered that further work on this phenomenon may contribute to an understanding of the general mechanism of the pitting corrosion of metals.

The anodizing of titanium in formic acid to produce a micropitted surface as an aid to anti-galling, lubrication and adhesion of surface coatings is covered by a patent application[4] made by the National Research Development Corporation.

Some New Intermetallic Compounds of Thorium of the Type Th_7X_3

As part of an investigation of the constitution of alloys of thorium with the metals ruthenium, rhodium, palladium, osmium, iridium and platinum, a series of 1-gm. samples of alloys containing up to 33 atomic per cent of each precious metal was prepared by arc-melting the component materials in a zirconium-gettered argon atmosphere, weight losses on melting being negligible. Metallographic and X-ray results on as-cast and on annealed material suggest that the intermetallic compounds richest in thorium are: Th_7Ru_3, Th_7Rh_3, Th_2Pd, Th_7Os_3, Th_7Ir_3 and Th_7Pt_3. Each compound forms a eutectic with thorium and the composition and temperature of these eutectics are given in Table 1. The solid solubility of each metal in thorium and the age-hardening behaviour of thorium-rich alloys have also been investigated.

Alloys corresponding to the five compounds, Th_7X_3, were brittle and powders for X-ray studies were prepared by crushing in air; powder patterns were obtained with a Guinier-type focusing camera using monochromatized copper radiation. These X-ray films were indexed on the basis of a hexagonal lattice, systematic extinctions of the $h\,h\,\overline{2h}\,l$ reflexions were noted when l was odd and the observed intensities show good agreement with those for the Th_7Fe_3 structure, space group $C^4_{6v} - P\,6_3mc$. Lattice parameters, axial ratios and X-ray densities for the new compounds are given in Table 2.

Table 1

System	Phases in the eutectic	Composition of the eutectic (percentage of precious metal)	Melting point of the eutectic (deg. C.)
Th – Ru	Th + Th_7Ru_3	16 ± 1	1,262 ± 12
Th – Rh	Th + Th_7Rh_3	20 ± 1	1,237 ± 12
Th – Pd	Th + Th_2Pd	22 ± 1	1,112 ± 12
Th – Os	Th + Th_7Os_3	14 ± 1	1,287 ± 12
Th – Ir	Th + Th_7Ir_3	15 ± 1	> 1,300
Th – Pt	Th + Th_7Pt_3	17·5 ± 0·5	1,242 ± 12

Table 2

Compound	'*a*' (Å.)	'*c*' (Å.)	*c/a*	X-ray density (gm./c.c.)
Th_7Ru_3	9 969	6·302	0·632	11·82
Th_7Rh_3	10 031	6 287	0·627	11·71
Th_7Os_3	10 031	6 296	0·628	13·27
Th_7Ir_3	10 076	6 296	0·625	13·40

CRYSTALLOGRAPHY

X-Ray Correlation of the *A-B* Layer Order of Cadmium Selenide with the Sign of the Polar Axis

Cadmium selenide (CdSe) is typical of the hexagonal semiconducting compounds formed from elements of Group II and Group VI of the Periodic Table. It possesses the wurtzite structure and contains a unique polar axis (the *c*-axis). Compression along this axis produces opposite electric charges on the basal faces, which also differ in their response to etching and in other properties. An examination of the crystal structure as shown in Fig. 1 shows the polarity clearly. Viewed normal to the *c*-axis, pairs of closely spaced cadmium–selenium layers are seen. The 'cadmium side' and the 'selenium side' are defined in Fig. 1.

For an understanding of the polar physical and chemical effects it is important to know which is the cadmium and which is the selenium side of the *c*-axis. It is possible to make such an identification by observing the effects of anomalous X-ray dispersion on the intensity of the X-rays reflected from the positive and negative sides of the basal planes $(00.l)$ and $(00.\bar{l})$. Previous workers have investigated cubic zinc sulphide, gallium arsenide and indium arsenide in such a manner[1-3]. To our knowledge, this communication reports the first application of this

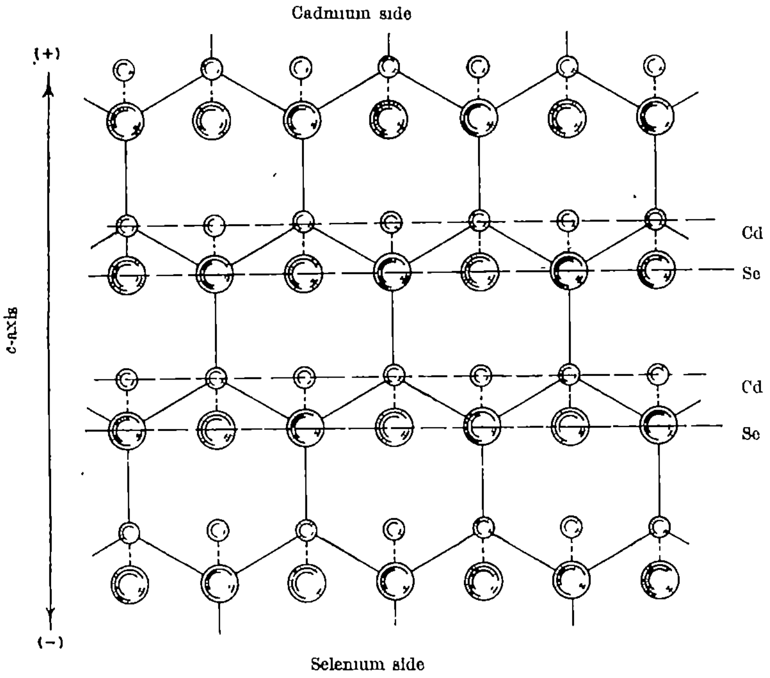

Fig. 1. Alternate layers of cadmium and selenium parallel to the (00.1) surfaces

technique to a wurtzite structure. By making dispersion corrections to the atomic scattering factor, the structure factor ratio $\frac{|F(00.l)|^2}{|F(00.\bar{l})|^2}$ (which is proportional to the ratio of the integrated intensities) can be calculated[4]. These theoretical ratios calculated for copper $K\alpha$ radiation are shown in Table 1.

Table 1. ROTATED INTEGRATED INTENSITY RATIOS

Plane	Theoretical intensity ratio $\frac{\lvert F(00.l)\rvert^2}{\lvert F(00.\bar{l})\rvert^2}$	Observed intensity ratio
00.2	0·860	0 862
00.4	1 000	0 973
00.6	1·225	1 241
00.8	1·000	1 045

The experimental procedure is quite exacting. A circular plate of cadmium selenide, the surface of which was orientated to within 3 min. of arc with the (00.1) plane, was etched and given an optical polish with 0·3μ alumina. Measurements with an optical flat indicate that both surfaces were slightly rounded but were flat to 10 fringes. Next, the disk was placed on a bed of wax in a cylinder which was inserted into the rotating flat specimen spinner of a standard 'Norelco' diffractometer. The polished crystal was pushed up against an optical flat which was held against the top surface of the specimen holder. When the interference rings were centred, the crystal was locked into position. To test the parallelism of the crystal surface with the plane of the specimen holder, the latter was rotated by motor while a distant light source was reflected off the rotating crystal surface. The steadiness of this optical image proved to be an extremely sensitive test of the line-up. The experimental values for the integrated intensities were obtained by counting while simultaneously rotating the crystal at 77 r.p.m. and slowly scanning the entire peak at 1/8° (2θ) per min. After the rotated integrated intensities were measured on one side, the crystal was turned over, aligned, and the same process was repeated (care being taken that all conditions were identical for any two $(00.l)$ $(00.\bar{l})$ reflexions). For different peaks various aluminium filters were used so that the counting-rate fell within the linear response range of the scintillation counter. Table 1 compares a typical set of results with the corresponding theoretical values.

The side of the crystal proved to be the cadmium side by the X-ray data of Table 1 was found to become positively charged on extension. By the sign convention of the I.R.E. 1949 Standard on Piezoelectricity the + end is therefore the outward directed normal from the cadmium side.

Having established this correlation, other differentiating properties of opposite (00.1) surfaces which have been correlated to the piezoelectric sign can also be related to the *A*–*B* layer order. Table 2 is a tabulation of some of these correlations for cadmium selenide.

Considering the similar character of all wurtzite and sphalerite compounds, it would appear reasonable for these compounds to show the same type of correlation as cadmium selenide, namely, the more metallic layer will be in the +c direction, as defined by the piezoelectric sign. This is in keeping with the findings for zinc sulphide and (by inference from the etching behaviour) for gallium arsenide and indium arsenide[1–3]. Any theory which attempts to explain the differentiating properties of the opposite (00.1) surfaces of wurtzite and the opposite (111) surfaces

Table 2. CORRELATION OF *A*–*B* LAYER ORDER WITH OTHER PROPERTIES WHICH DISTINGUISH THE OPPOSITE (00.1) SURFACES OF CADMIUM SELENIDE

Property	(00.1) surface. Outward normal to surface points in + *c* direction	(00.1) surface. Outward normal to surface points in − *c* direction
Sign of piezoelectricity on extension	(+) As defined by 1949 I.R.E. convention	(−)
A–*B* layer order	See Fig. 1	
Etching characteristics in aqua regia (excess selenium removed)	Shiny, symmetric pits bevelled edges Equal or slower etch rate	Dull or cratered, no symmetry pits, no edge bevelling. Equal or faster etch rate
Relative sign of electrolytic solution potential 1 : 1 aqua regia	(+) More 'noble' by 50–70 mV	(−)
Crystal habit at positive and negative ends	More complex pyramid development	Prominent face is the pedion. Pyramids small or absent

for sphalerite compounds must be compatible with these findings.

OCEANOGRAPHY

Organic Acids in Pacific Ocean Waters

Organic acids dissolved in waters of the Pacific Ocean were isolated by : (1) solvent extractions with carbon disulphide and chloroform, and (2) by co-precipitation with ferric hydroxide sols.

The solvent extractions were carried out on 15·3–20·0 l. of sea-water samples freed of particulate matter by filtration through '*HA* Millipore' filters (pore size : 0·45μ). The residues from chloroform and carbon disulphide extracts were methylated with methanol and a trace of concentrated sulphuric acid, and these products were then submitted to gas chromatographic analysis using an 'Aerograph' model 110-*C* gas chromatograph (Wilkens Instrument Co., Walnut Creek, California) incorporating 5- and 10-ft. Craig polyester succinate columns. The fatty acid esters isolated were identified by their retention times on the column with respect to known fatty acid esters and in the case of the methyl esters of palmitic and stearic acids by collection from the column and subsequent infra-red spectra. Table 1 lists the fatty acids isolated in μgm./l., and includes pertinent data on sample location and depth, extraction *p*H, and indicates the amounts of the unknown fatty acids C_x, C_y and C_z. From their infra-red spectra, C_x, C_y and C_z are indicated to be fatty acid esters. Their relative positions on the gas chromatographic traces gave retention times identical with the C_{15}, C_{17} and C_{19} normal, saturated fatty acid esters. Fig. 1 illustrates two representative traces for samples 47-*A* and 10-*A*.

To determine the percentage recovery of the fatty acids from sea-water a tracer experiment was run using palmitic acid-1-^{14}C (Nuclear-Chicago, Cat. No. *CFA*-23), added as 2,345 c.p.m. to each 2·40–2·48 l. sample of filtered sea-water prior to extraction with chloroform. The samples were acidified with hydrochloric acid to a *p*H of 2·0, and the solvent

(2) Reagent control using distilled water and working up the ferric hydroxide precipitate as above.

extracts, freed of solvent, were plated on 1-in. copper planchets and counted with a Nuclear-Chicago model-*D*47 gas-flow counter. The free acids were then esterified and the methyl esters submitted to gas chromatographic analysis. The effluent methyl palmitate was collected from the column and counted to obtain the overall recovery. The yields and amounts of the saturated, mono-unsaturated and di-unsaturated acids based on the methyl palmitate recovery are shown in Table 2. There was no indication of the presence of the C_{15}, C_{17} and C_{19} esters in the tracer experiment.

The co-precipitation of organic acids with ferric hydroxide was effected by the initial addition of 10 mgm./l. of iron(III) as ferric chloride to each sample of filtered sea-water, previously acidified to a *p*H of 2–3 with hydrochloric acid. The ferric hydroxides sols were precipitated with 2 *N* potassium hydroxide to a final *p*H of 6·1–6·5, and the precipitate collected by centrifugation. This material was worked free of chloride ion, redissolved in hydrochloric acid to a *p*H of 2·0 and passed through 'Dowex-50' cation exchange resin (*H*-form, 200–400 mesh, 4 × cross-linked). The acids were eluted with 0·1 *N* hydrochloric acid, and the eluate adjusted to a *p*H of 3·5 with 2 *N* potassium hydroxide. The solution was taken to dryness *in vacuo* and the residual salts extracted repeatedly with *iso*propyl alcohol. The alcoholic extracts, dried and freed of potassium chloride, were worked up to give light yellow solids, showing blue-green fluorescence, and giving negative tests for halogens, phosphorus, nitrogen, boron, sulphur and iron. The yields and carbon–hydrogen analyses of this material from two stations are shown in Table 3. The ash-free material gave an average molecular weight of 395 and an equivalent weight of 208. Hydroxyl and carboxyl groups were indicated by the infra-red spectra (Fig. 2) and spot tests. Tests for unsaturation and aromaticity were negative. Ultra-violet absorption curves showed only increasing absorption from 700 to 220 mμ. Attempts to separate this mixture by paper chromatography and paper electrophoresis were unsuccessful.

BIOPHYSICS

Use of Potassium Tartrate for Equilibrium Density-gradient Centrifugation of Animal Viruses

Density-gradient centrifugation of both the velocity and equilibrium types has been applied for separating and purifying plant viruses such as tobacco mosaic and potato yellows[1], and also very recently to animal viruses such as Rous sarcoma[2], Shope fibroma[3] and polyoma[4]. Equilibrium banding with satisfactory recovery of biological activity has usually been achieved in rubidium or cæsium chlorides after centrifugation for approximately 24 hr. Some viruses are, however, inactivated by these salts, and others, as, for example, Rous sarcoma, require stabilization by albumin and citrate[2]. Non-equilibrium sedimentation in glycerol gradients has been used to purify Shope papilloma[3]; and reasonably sharp peaks of influenza and Newcastle disease viruses, and also of vaccinia hæmagglutinin, may be obtained after brief centrifugation in sucrose gradients of the velocity-sedimentation type[5].

In this communication we describe a simple method for equilibrium banding of some animal viruses, using preformed density gradients of neutral potassium tartrate. Equilibrium is obtained very rapidly in this salt, which possesses other advantages also in that concentrated solutions do not inactivate the infectivity or hæmagglutinins of the various viruses so far examined. Furthermore, the salt is inexpensive and no additional purification of the analytical reagent is necessary.

Gradients were prepared at 4° using two small mixing chambers, one of which was filled with concentrated potassium tartrate (varying from 35 to 60 per cent in different experiments), and the other with 2 per cent tartrate. The *p*H of the solutions was adjusted to 7·5. Virus samples (0·25–0·5 ml.) were then graded on to the tartrate gradient in an equal volume of the 2 per cent salt. Centrifugation was carried out in the Spinco *SW*39 head at 39,000 r.p.m. Most viruses banded satisfactorily in equilibrium after 1–2 hr.; but vaccinia hæmagglutinin, for example, may require 6 hr. centrifugation for close banding. After centrifugation, fractions were usually obtained by piercing the bottom of the centrifuge tube with a needle and running denser salt (70 per cent tartrate) up from below ('top unloader').

In some experiments the samples were collected by a novel method developed by one of us (R. S. E.), in which the centrifuge tube was lowered into a mixture of alcohol and dry ice and held there until the contents were frozen. The centrifuge tube was removed and cut rapidly into ten or more segments with a small saw. Each segment was then transferred to a tube and allowed to thaw. Contrary to expectation, control experiments showed that carefully controlled freezing did not distort or displace boundaries significantly, provided that the band was at least one-third of the way down the centrifugation tube. In several experiments, samples from equal volumes of virus centrifuged at the same time in the three buckets of the *SW*39 head were collected by three different methods, namely, dripping from the bottom of the tube, dripping from the top of the tube in the top-unloader, and by 'freezing-and-sawing'. In every instance the latter technique yielded as sharp, and frequently sharper, bands than those obtained by dripping. The freezing-and-sawing technique also offers the advantage that each fraction is collected independently, and there is thus less danger of contamination from one fraction to another than when all the samples are passed through the same orifice.

A typical sedimentation diagram from a sample of influenza *A* virus centrifuged in a tartrate gradient is shown in Fig. 1. It will be seen that after centrifugation for only 40 min. the majority of hæmagglutinin is recovered in equilibrium in a single fraction, and that only traces of activity are recovered in adjacent tubes of higher or lower densities. Equally sharp equilibrium peaks were obtained with influenza *B* and Newcastle disease viruses. In all cases the recovery of hæmagglutinin and infectivity was quantitative; and with Newcastle disease virus the titre of the most active hæmagglutinin fraction was actually from two- to four-fold higher than that of the original virus. The latter effect is presumably due to the removal of an inhibitor elsewhere on the gradient. The specificity of each hæmagglutinin was checked by neutralization with the appropriate antiserum. The most concentrated tartrate solution used (60 per cent) agglutinates a 1 per cent suspension of chicken erythrocytes to a dilution of 1 : 2–1 : 4 only.

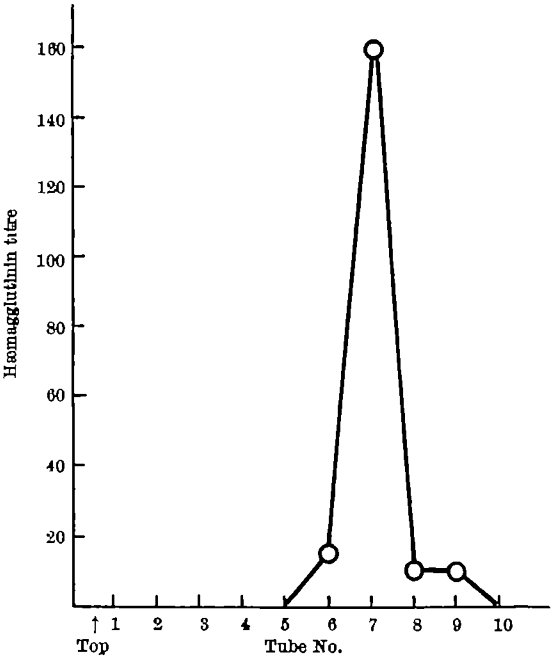

Fig. 1. Sedimentation diagram of influenza *A*, strain *MEL*, after centrifugation in a potassium tartrate gradient for 40 min. at 39,000 r.p.m. in the Spinco *SW*39 head. Maximum potassium tartrate concentration, 48 per cent. Virus diluted 1 : 2 in buffered normal saline, and 0·25 ml. placed on gradient

Potassium tartrate gradients are thus more convenient in many ways than gradients prepared with heavy salts such as cæsium and rubidium chlorides for equilibrium banding of several animal viruses. It seems likely that tartrate gradients could readily be applied for the concentration and purification of many other viruses and macromolecules, for the separation of virus mixtures, and for the separation of components from one virus. For example, as will be described in detail elsewhere, the vaccinia hæmagglutinin may be banded relatively sharply in 45 per cent potassium tartrate, whereas most of the infectious particles are found at the bottom of the gradient at this concentration[6]. Experiments are in progress in an attempt to sharpen the resolution of these and other viral components.

We are indebted to Dr. Carl Woese for valuable advice on gradient techniques. This work was supported by a research grant (*E* 2213-*C*2) of the U.S. Public Health Service, and by a grant from the Committee on Atypical Growth, Yale University.

CHEMISTRY

Rapid Identification of High Polymers using a Simple Pyrolysis Unit with a Gas–Liquid Chromatograph

For some years it was standard practice in these laboratories to pyrolyse polymers in an intimate mix with ignited silver sand under carefully controlled conditions in an inert partial atmosphere. The degradation products were fractionated and examined by gas–liquid partition chromatography. The performance of the entire process in one stage was considered as a natural development of the technique, and the piece of apparatus to be described is now in regular use.

The considerations of design and operation of the pyrolyser were governed by the following factors: (*a*) The polymer degradation must be complete and should occur in the shortest possible time. A very thin film of polymer is therefore required and this will have the great advantage of minimizing secondary reactions between degradation products[1]. (*b*) 'Flash' depolymerization requires rapid heating of the very thin polymer film to the degradation temperature. This may be achieved by a large heating area relative to the mass of polymer. (*c*) Gaseous diffusion of the degradation products must be a minimum, therefore the pyrolysis coil must be in the chromatographic column itself and sited as near the surface of the packing material as is practicable. (*d*) To reduce the risk of condensation of any part of the gaseous sample the pyrolysis coil must be located within the column heater zone.

The pyrolyser (Fig. 1) consists of a rubber bung through which pass two pieces of 6 *BA* brass studding about 4·25 in. long; they project 1·5 in. above the bung and 2 in. below it. The upper ends are sleeved with polyvinyl chloride and terminate in a 5-amp. connector block, the lower ends are glass sleeved and terminate in screwed connector bushes. The pyrolysis coil itself is a 6-in. length of 28 standard wire gauge nichrome wire coiled to 4-mm. diameter over its middle 4 in., the two ends being fixed in the two screwed connector bushes. The associated electrical circuit is shown in Fig. 2.

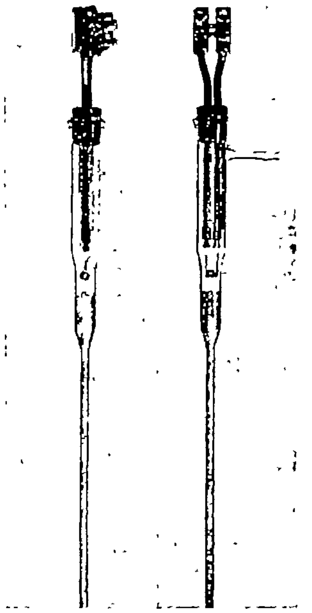

Fig. 1. Two views of the pyrolyser in position in a modified chromatographic column (quarter actual size)

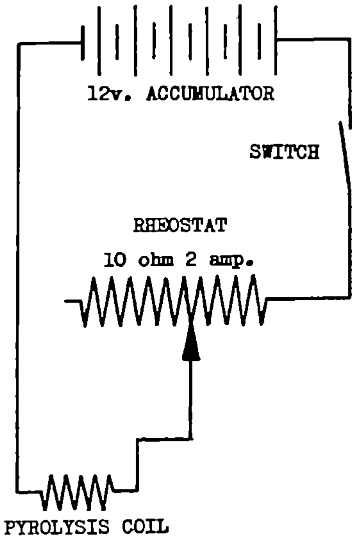

Fig. 2. Pyrolyser circuit diagram

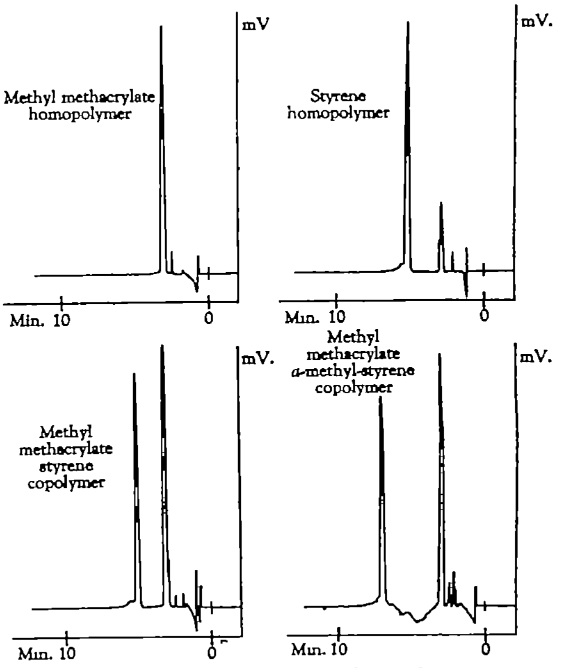

Fig. 3. Pyrolysis chromatograms of two homopolymers and two copolymers obtained on a 12·5 per cent polyethylene glycol succinate column operating at 80° C.

A very thin film of polymer, from a dilute emulsion or solution, or a dispersed gel, is cast on the filament, dried, and the assembly inserted in the top of a modified chromatographic column. The carrier gas flow is then started, and, after allowing a short time for the flow equilibrium to be set up, the coil is 'fired' at about 500° C. for 2–5 sec. The pyrolysis products are immediately swept on to the column by the carrier stream and chromatographed. Completeness of degradation can be checked by re-firing the coil at 1,000° C. when there should be no further signal from the detector due to degradation products.

Characteristic fingerprint chromatograms for homopolymers of methyl methacrylate and styrene, and copolymers of methyl methacrylate with styrene and methyl methacrylate with α-methyl-styrene, are shown in Fig. 3. When examining copolymers such as these, reliable quantitative assays of the monomers can be obtained, but with more complex monomers and co-monomers the method is only semi-quantitative.

Future modifications will include a precise method of filament temperature measurement, a filament of lower heat capacity—possibly in the form of a strip—and the development of a miniature version of the apparatus.

An Enrichment Trap for Use with Capillary Columns

In the course of an investigation into the volatile substances produced during the cooking of potatoes, difficulties were experienced when using gas chromatographic techniques[1] in the injection of small quantities of vapour. A nylon capillary column, length 50 ft., internal diameter 0·01 in., coated with 15 per cent tritolyl phosphate, and a Lovelock small detector[2] were used. It was found that the conventional injection by syringe into a 100 : 1 by-pass system did not allow sufficient vapour to pass into the column. The by-pass of argon carrier gas could be reduced to 30 : 1 without seriously impairing the resolution of the components being studied, but this still did not provide sufficient sample for detection. This method of injection was abandoned in favour of an enrichment trap. The enrichment trap technique for use with packed columns has been described[3].

The volatile substances given off from 1 kgm. of potatoes boiling in a 3-litre round-bottom flask were removed by a stream of nitrogen and freed from water vapour by passing successively through a glass U-shaped trap, cooled with solid carbon dioxide – acetone, and a similar trap cooled with liquid oxygen. The escaping volatile substances were then retained in a U-shaped trap consisting of 10 in. of 0·01 in. diameter nylon capillary coated with the same phase as the column. After collection for 20 min., the trap was disconnected and re-connected to the nylon capillary column (Fig. 1), while still immersed in liquid oxygen. With the carrier gas flowing, the trap was kept at – 183° C. until the air peak signal was obtained on the recorder, and then immersed in hot water at approximately 60° C. for 20 sec., removed, and left at room temperature. The chromatogram obtained showed a good separation of components, along with a small air peak which was a useful guide for obtaining relative retention times.

Confirmatory infra-red analysis cannot be obtained when using the nylon capillary column. The enrichment trap can, however, be used satisfactorily for mixed chromatography. The capillary trap is filled with unknown volatile substances as described above, then connected to the column as before and a small sample of authentic vapour, suspected to be present in the unknown, injected by syringe into the port situated in front of the 30 : 1 by-pass system. Thus 1/30th of the sample passes into the trap and is retained. The capillary trap is then disconnected from the column system and connected to a similar empty trap held in liquid oxygen. The original trap containing the unknown volatile substance and authentic sample is immersed in hot water causing the contents to mix intimately. A hyperdermic syringe needle is fitted to the first trap and an open syringe is used to propel the volatile substances from the first trap to the second trap. The second trap is then connected to the column as before and the contents chromatographed. The two-trap system is necessary since it was found that intimate mixing did not occur in the first capillary trap.

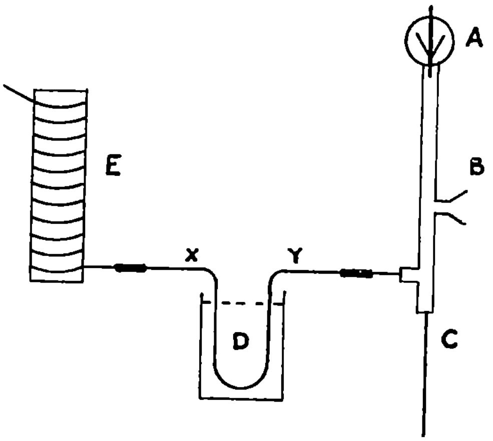

Fig. 1. *A*, Argon flow regulator; *B*, syringe injection port; *C*, nylon capillary by-pass; *D*, enrichment trap immersed in liquid oxygen; *E*, 50-ft. nylon capillary column. Volatile substances are collected in the trap with the gas flowing in an *XY* direction, but released as shown (ref. 3)

I wish to acknowledge the encouragement given by Mr. A. E. Joyce.

Thermal Stability of Titanium Dioxide

Vorres and Dutton[1] and Vorres and Donohue[2] have recently described the preparation and crystal structure of titanium dioxide. Its decomposition in dry and moist air and dry nitrogen has been determined as part of our investigations of the thermal decomposition of some inorganic fluorides.

The results presented in Table 1 were obtained by the use of an atmosphere-controlled thermogravimetric balance the construction and operation of which have been described elsewhere[3]. The reported isothermal weight-loss data for runs 3 and 4, made in dry air and nitrogen, are maximum losses, and the X-ray examinations of their residues showed only titanium dioxide (anatase). Several additional experiments were carried out in a horizontal 'Vycor'

Table 1. Isothermal Weight-loss Data for Titanium Dioxide

Run No.	Temperature (deg. C.)	Atmosphere	Duration of the run (min.)	Total weight-loss (per cent)
1	340	dry air	4,285	47·0
2	400	dry air	1,350	54·9
3	460	dry air	112	60·0
4	440	dry nitrogen	393	59·9
5	340	moist air	330	22·3
6	400	moist air	186	24·2
7	455	moist air	88	28·5

tube at 460° C. with a stream of dry air flowing through the tube. In these experiments a white material condensed on a water-cooled cold finger placed 2 in. from the heated sample contained in a platinum boat. This condensate was very hygroscopic and reacted vigorously with water to form a clear, colourless, highly acidic solution which gave positive qualitative tests for both titanium and fluoride ions. These results agree well with the reported characteristics[4,5] of titanium fluoride. It was concluded that the fluoride formed during the decomposition of titanium dioxide and was swept away by the air stream (b.p. of titanium fluoride is 284° C.[5]).

From this information it was concluded that titanium dioxide in a dry atmosphere of air or nitrogen decomposed as follows:

$$2TiOF_2 = TiO_2 + TiF_4 \qquad (1)$$

The calculated loss of weight on the basis of this equation, if all the fluoride is lost, is 60·8 per cent, which is in good agreement with runs 3 and 4. Fig. 1 indicates that this decomposition begins at 150–200° C. and is complete by 500° C. when the heating-rate is 4° C. per min.

The weight-loss values for runs 5, 6 and 7 made in a moist atmosphere are maximum values. X-ray patterns of the residues show only titanium dioxide (anatase). From this evidence the simplest reaction is written as:

$$TiOF_2 + H_2O = TiO_2 + 2HF \qquad (2)$$

If only hydrogen fluoride is lost, the calculated loss of weight is 21·6 per cent. This value agrees well with run 5. However, the observed losses of runs 6 and 7 are noticeably greater.

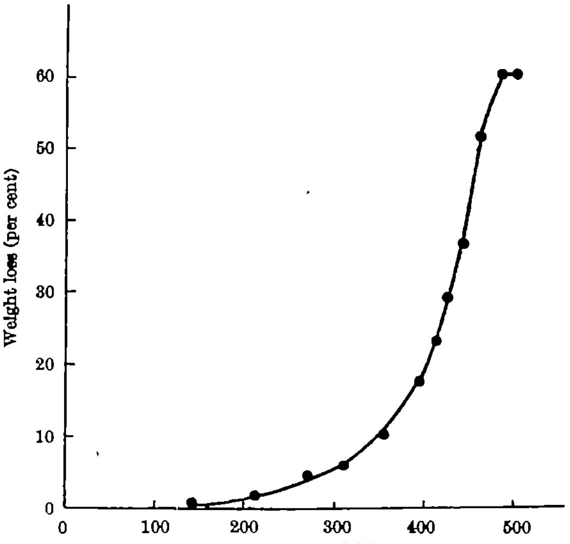

Fig. 1. Weight-loss of titanium dioxide heated at the rate of 4 deg. C. per min. in dry air

The following explanation for the observed deviations of runs 6 and 7 is suggested. Reaction (2) can be considered as the summation of the two reactions:

$$2TiOF_2 = TiO_2 + TiF_4 \qquad (3)$$

$$TiF_4 + 2H_2O = TiO_2 + 4HF \qquad (4)$$

If reaction (3) is the first step, then the loss of any titanium fluoride from the crucible before it is hydrolysed to titanium dioxide will cause a loss of weight in excess of that calculated for reaction (2).

It will be noted that the deviation from the expected loss on the basis of the simple one-step case (reaction (2)) increases for higher-temperature runs. At higher temperatures it was observed that the velocity of the decomposition was greater, so the probability of escape of titanium fluoride before it can react with water vapour in the atmosphere is also greater. This effect also depends, among other things, on the partial pressure of the water in the atmosphere, which was not considered.

A similar deviation with respect to increasing temperature was observed in the decomposition of Na_2SiF_6 in moist air[3].

Ethyl Branching in the Fischer–Tropsch Synthesis

Current schemes for explaining chain-growth in the Fischer–Tropsch synthesis[1–4] do not permit the formation of an ethyl-branched hydrocarbon. We wish to report the identification of 3-ethylpentane in a hydrogenated Fischer–Tropsch synthesis product. A compound with this carbon skeleton has not hitherto been found in the product. Quantitative analyses by gas chromatography give a mole ratio of 2,3-dimethylpentane to 3-ethylpentane of 1·5. Weitkamp[1] found that 2,3-dimethylpentane constituted 0·9 volume per cent of the hydrogenated C_7-hydrocarbons from the synthesis product.

The Fischer–Tropsch product was made by passing 1 hydrogen : 1 carbon monoxide gas over a reduced-iron catalyst at 260° C., 21·4 atmospheres, and an hourly space-velocity of 300. The product was distilled to give four fractions, boiling from 60° to 170° C. These fractions were hydrogenated over platinum oxide catalyst. (It has been shown[4] that the distribution of skeletal isomers in the Fischer–Tropsch synthesis is identical for paraffins and olefins.) These hydrogenated fractions were chromatographed on Davison No. 950 silica gel, at column temperatures from − 10° to + 5° C., to isolate the hydrocarbon portions. Olefin-containing portions were re-hydrogenated and re-chromatographed. The combined saturated-hydrocarbon fractions were then distilled into narrow-boiling fractions.

Gas-chromatographic examination of these hydrocarbon fractions was made on a 26·5 ft. by 4·5 mm. internal diameter stainless steel column, coiled as a helix, containing 79 gm. of packing made in the weight ratio 12 parts tri-cresylphosphate to 88 parts 35–45 mesh 'Chromosorb'. By measuring the retention time relative to 2-methylhexane, a compound known to be present, 3-ethylpentane, was identified in these fractions.

Confirmation of 3-ethylpentane in these fractions was obtained by trapping-out the gas-chromatography peak at liquid nitrogen temperatures and analysing the 'freeze-outs' on a mass spectrometer. The 3-ethylpentane peak and part of the immediately preceding 3-methylhexane peak were in the freeze-outs. The hydrocarbon portions of duplicate freeze-outs analysed as 87 per cent 3-ethylpentane, 13 per cent 3-methylhexane, and 88 per cent 3-ethyl pentane, 12 per cent 3-methylhexane.

In the Fischer–Tropsch synthesis, 3-ethylpentane might be formed in any one of several ways: (1) The carbon chain might grow by adding a one-carbon unit to a methyl branch already present such as in the 3-methylpentane chain. (2) A one-carbon unit is added to 2-ethyl-1-butene (Weitkamp[1] shows that this is present in the product) by an oxo-type reaction. (3) Reaction occurs between a C_5-chain and a two-carbon unit, that is, 'multiple build-in' as suggested by Hall *et al.*[5]. (4) Isomerization of the carbon skeleton occurs to form 3-ethylpentane, but this seems unlikely.

This work is part of a larger project on the analysis of Fischer–Tropsch synthesis products through the C_7-compounds. The work in its entirety will be reported later. We wish to acknowledge the following who have contributed to this particular phase of the work: C. Zahn, G. Pantazoplos and A. G. Sharkey, jun.

BIOCHEMISTRY

Hæmoglobins, Myoglobins and Erythrocruorins: a Proposal for modifying the Present Terminology

THE present terminology for those protohæm respiratory pigments which combine reversibly with oxygen, in which the terms hæmoglobin, myoglobin and erythrocruorin are used in varying senses by different authors, is far from satisfactory. Keilin and Hartree[1] showed that a convention introduced earlier by Svedberg[2], whereby all invertebrate pigments of this type were to be designated as erythrocruorins, was no longer justified on the basis of current knowledge. They suggested instead that 'hæmoglobin' should be used as a general term for both vertebrate and invertebrate pigments, and that the term erythrocruorin should be abandoned. According to their suggestion any given pigment should be identified by its origin, as in *Planorbis* hæmoglobin, muscle hæmoglobin, etc. It is with regard to the latter designation that this terminology immediately ran into difficulties.

I may recall that at the time when Keilin and Hartree made their proposal it was generally held that myoglobin (muscle hæmoglobin) and hæmoglobin in vertebrates were fundamentally different, and differences between them were always emphasized. Thus, Roughton, quite recently, commented[3] that: "It is an old creed that these two compounds are physicochemically similar, but this creed must now go, for the more intimately one studies them, the more frequent are the differences that one finds". Hence, Keilin and Hartree's proposal to equate myoglobins with hæmoglobins did not meet with general acceptance. However, following the work of Kendrew *et al.*[4,5], and of Perutz *et al.*[6], it might appear that such a proposal could now be defended. Yet the net result of the X-ray work, which proves that the tertiary structure of mammalian myoglobin and hæmoglobin is very closely similar, has been to demonstrate that there are at present no physicochemical criteria by which one can distinguish between these compounds in all cases. It might seem, therefore, that we should abandon the term myoglobin, and use instead the older names, muscle hæmoglobin or tissue hæmoglobin. Yet this is not so since there is a very real distinction to be made between the two, which is implicit in the term "tissue hæmoglobin". Hæmoglobins function in the transport of oxygen to the tissues and therefore occur in conjunction with some kind of circulatory system. They may or may not be found in corpuscles. Myoglobins are usually saturated with oxygen, remain within the tissues where they are located, and function to provide a reserve of oxygen against short-term deficits.

Keilin and Hartree summed up their intentions thus: "To avoid confusion and unnecessary complications of the nomenclature, the classification of all biologically active protein compounds, such as oxygen carriers or enzymes, should be based not upon their physico-chemical properties as proteins but upon their specific biological activities and the nature of their active, or prosthetic, groups". The distinction between myoglobins and hæmoglobins, made above, is in line with this aim. However, it is obviously unsatisfactory to use 'hæmoglobin' as a generic name for both groups of pigment. Furthermore, it would have the very real disadvantage that for many investigators 'hæmoglobin' means a compound with four hæm groups per molecule, with molecular weight 68,000, and all the other properties of mammalian hæmoglobins. Finally, one requires a term which carries no connotations of any sort other than that the pigment contains protohæm and combines reversibly with oxygen, for use in those cases where the given pigment cannot be classed as either myoglobin or hæmoglobin through lack of data; and possibly also if it should be found impossible to do so. For example, the recent work of Scholander[7] has raised the possibility, which seems especially attractive when considering certain invertebrate animals, that tissue pigments may act to promote the passage of oxygen to the tissues, rather than, or in addition to, carrying a reserve of oxygen. (The storage hypothesis has not found favour with investigators in certain specific cases, compare Eliassen[8].)

It is now possible to conceive a classification which takes account of these considerations, which has historical and logical justification, and which causes the least change to the existing terminology. The term 'erythrocruorin' (red pigment) was introduced by Lankester[9] as a general term for all protohæm oxygen-combining respiratory pigments, without any implication as to the structure or function of the pigment, and in contrast to the analogous pigments of certain marine worms which he called 'chlorocruorins' (green pigment)—a term which is still used in this sense[10]. It is therefore proposed that the term erythrocruorin be used for all known or presumed protohæm respiratory pigments which are known or presumed to be capable of undergoing reversible oxygenation. All erythrocruorins which are known or presumed to function in oxygen storage can be classed as myoglobins. It will be noted that this scheme maintains the present usage for vertebrate erythrocruorins, but also incorporates it into a general scheme for both vertebrate and invertebrate pigments.

It may be noted also that the prefix 'myo-' could possibly be used for pigments other than erythrocruorins which are analogous to myoglobins. Manwell[11] has already used the term myohæmerythrin in this sense.

Consistent use of the terminology suggested here will be found to lead not only to greater flexibility in discussion but greater precision also. It is hoped that these advantages, together with those enumerated above, will commend themselves to other workers in the field.

Rehardening of Softened Enamel Surfaces of Human Teeth by Solutions of Calcium Phosphates

Rehardening of softened human enamel has been attempted in the past[1-3], but has not been clearly demonstrated since the earlier workers were not able to show that the softened material was not lost. Knoop hardness measurements provide a quantitative and sensitive measure of surface changes, and any loss of surface can be shown by alterations of the size and shape of the previously placed indentations. This communication describes conditions which have been developed for rehardening tooth surfaces, softened by a prior treatment with a buffer.

A Kentron microhardness tester was used with Knoop diamond indenter, as described previously[4,5], for following changes in surface hardness. Human teeth were tested for hardness initially, after softening by acetate buffer, and after treatment in calcium phosphate solutions. For each determination, ten indentations were made, and the hardness was expressed as an average Knoop hardness number. The initial indentations were often remeasured at the end of the experiments, and no change of length was noted. Softening of the teeth was produced in groups of ten by treatment with 1 litre of acetate buffer 0·001 *M*, *p*H 5·50, for 2–12 hr. at 37°.

For the preparation of rehardening solutions, two calcium salts were used, secondary calcium phosphate dihydrate (calcium/phosphorus molar ratio, 1·0) and synthetic hydroxyapatite (Ca/P ratio, 1·67). A weighed amount of salt (50 m.moles of calcium) was dissolved in twice this molar concentration of hydrochloric acid, and the volume was made up to 1 litre. From this stock solution, aliquots corresponding to 0·75 or 1·25 m.moles of calcium were pipetted into bottles containing distilled water at 37°. Aliquots of potassium fluoride stock solution (0·02 *M*) corresponding to 1–7 p.p.m. were added, if desired. The volume was made up to about 480 ml. with distilled water and sufficient potassium hydroxide (0·05 *M*) was added to bring the *p*H to predetermined values. The final volume was adjusted to 500 ml. The solutions were metastable, the *p*H dropped during the period of treatment, and some precipitation occurred.

Softened teeth were kept in pairs in 500 ml. of the rehardening solutions at 37° C. without stirring, and their hardness was determined at various time-

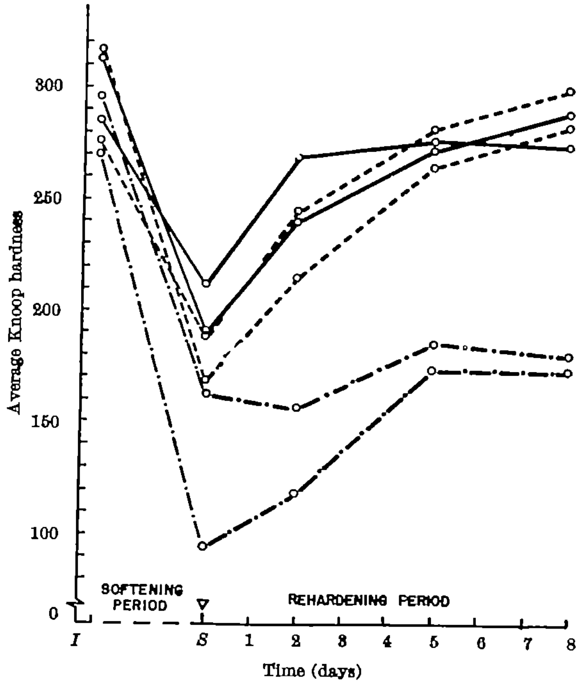

Fig. 1. Rate of rehardening of softened enamel surfaces as related to the extent of softening. *I*, Initial hardness; *S*, hardness after treatment with acetate buffer for 2 hr.: ——; 4 hr., – – –; 8 hr., — — —. Rehardening solution: Ca, 2·5 m.moles/l.; Ca/P, 1·0; *p*H 7·0; changed every 24 hr.

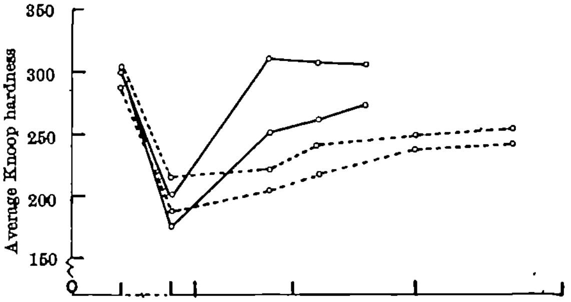

Fig. 2. Effect of fluoride on the rate of rehardening of softened enamel surfaces. *I*, Initial hardness; *S*, hardness after softening in acetate buffer for 4 hr. 1 p.p.m. fluoride, ——; no fluoride, – – –. Basic rehardening solution: Ca, 1·5 m.moles/l.; Ca/P, 1·67; *p*H 7·3; changed every 2 hr.

intervals as indicated in Figs. 1 and 2. The results in this communication are representative of rehardening experiments involving a total of more than 300 teeth.

Fig. 1 gives the results for individual teeth obtained with solutions prepared from the secondary calcium salt (Ca/P ratio, 1·0) and changed daily. Preliminary results of this type were reported earlier[6]. Four of six teeth showed a return to the initial hardness after treatment for 8 days. The two teeth that did not show considerable rehardening were those softened for 8 hr. to a low hardness. This and other similar results showed that complete rehardening did not occur if the softening process had proceeded too far, below about 150 Knoop hardness number. This limit may be of considerable interest in that it may be the boundary between sound and carious enamel and represent the limit of possible natural reparative recalcification of enamel. Sobel and his associates[7] have shown that calcification takes place in two discrete stages, nuclei formation and subsequent crystal growth. The remineralization of these experiments may refer only to the stage of crystal growth.

The rate of rehardening was found to be more rapid for solutions with Ca/P ratios of 1·67, especially in the presence of small amounts of fluoride. The results are shown in Fig. 2. The teeth kept in 500 ml. of solution containing 1 p.p.m. of fluoride regained the initial hardness in 4 hr., whereas in the absence of fluoride the recovery was much slower.

The accelerating effect of fluoride ions on the rehardening of enamel adds a second explanation for the mechanism of fluoride protection from dental caries. In addition to producing more insoluble enamel, fluoride ions appear to affect the dynamic equilibrium between tooth surfaces and the oral fluid by accelerating the enamel remineralization.

Table 1. INHIBITION OF *in vitro* CARIES IN THE ARTIFICIAL MOUTH IN THE PRESENCE OF REHARDENING SOLUTIONS
(Calcium/phosphate, 1·67; calcium, 1 5 m.moles/l. fluoride, 0·3 m.moles/l., *p*H 7 1. Freshly prepared medium was used twice daily)

Hardness (Knoop hardness number)* Experimental (Culture medium + rehardening solution)		Control (Culture medium alone)	
Initial	After 5 days	Initial	After 5 days
188	176	235	86
226	205	282	81
262	269	261	96
278	262	249	82
295	283	273	29
298	285	291	20

* Average *S.D.* ± 14

The rehardened enamel was tested for resistance to abrasion by tooth brushing and for resistance to softening by a second exposure to the acetate buffer (*p*H 5·50) for 2–4 hr. Brushing caused no appreciable loss of surface material. For 34 teeth, the average rate of softening by the buffer was 19 ± 3 Knoop hardness number/hr. for the rehardened teeth as compared with 26 ± 6 Knoop hardness number/hr. for the original surfaces.

In the artificial mouth[8], teeth exposed to oral bacteria and a culture medium supersaturated with calcium phosphate and containing 6 p.p.m. fluoride were essentially unaltered after 5 days exposure (Table 1). The controls were softened to the limit of the sensitivity of the measurements.

This evidence for enamel rehardening emphasizes the dynamic nature of the enamel surface and the importance of the oral fluid in the carious process. Prevention and healing of initial carious lesions seem possible by modification of the composition of the oral fluid either systemically or locally.

Biliverdin in the Eyes of *Polyphemus pediculus* (L.) (Crustacea, Cladocera)

THE large median compound eye of the Cladocera begins its development as two separate rudiments which enlarge gradually and fuse in the mid-line. In the majority of Cladocera these rudiments are red in colour and gradually darken so that they are black just before fusion. In embryos of *Polyphemus pediculus* the eye rudiments are green in colour, and when treated with yellow nitric acid they give a positive Gmelin reaction, indicating the presence of a bile pigment.

A large sample of female *Polyphemus*, containing numerous embryos, was first extracted with acetone to remove carotenoids and then extracted with acid methanol (5 per cent hydrochloric acid), giving a deep olive-green solution. When this was diluted with water and shaken with chloroform the chloroform phase became blue in colour while the acid methanol phase became orange-brown. The chloroform phase was washed with dilute sodium bicarbonate, then with water and evaporated to dryness. When the pigment was redissolved in acid methanol the absorption spectrum showed a sharp peak at 374 mμ and a lower, more rounded, peak at 685 mμ. These are close to the absorption maxima of biliverdin hydrochloride; the small differences can be attributed to the presence of other substances in the extract.

The identity of the green pigment as biliverdin was confirmed by the addition of zinc acetate and a little iodine to a methanol solution in the presence of a trace of ammonia. The result was a green solution with a brilliant pink fluorescence in ultra-violet light, and a sharp absorption band at 635 mμ showing that the pigment had proto not meso side-chains.

The presence of biliverdin in the eyes of adults was demonstrated by selecting females without embryos and extracting with methanol. The addition of zinc acetate and iodine produced the same results as with the larger sample.

It has not been possible to demonstrate a Gmelin reaction in the eyes of adult *Polyphemus* because of the presence of large amounts of a dark masking pigment. This pigment is also extracted with acid methanol, but remains in the methanol phase when it is diluted and shaken with chloroform. Further studies are being made of this and similar pigments in other Cladocera; meanwhile, it is possible to say that they are similar in many respects to ommochromes, being insoluble in most organic solvents, but easily soluble in acids, and showing reversible changes in colour according to whether they are oxidized or reduced.

Biliverdin is rare in the Crustacea; it has been found only in the digestive gland of the crayfish *Cambarus*[1], and in the roots of certain parasitic cirripedes[2]. The present record of biliverdin in *Polyphemus* adds another crustacean order to the few known to include bile pigments in their metabolism[3]. It is interesting in this connexion to note that, although searched for, no bile pigments have been found in the cladoceran *Daphnia*[4].

PHYSIOLOGY

Magnesium Absorption in Sheep

Low levels of dietary magnesium precipitate hypomagnesæmia experimentally in lambs[1]. It is not known whether these findings are related to the hypomagnesæmia which occurs spontaneously in adult ruminants near parturition in autumn and spring on some pastures. The present communication reports an attempt to produce hypomagnesæmia in sheep, but with a different type of roughage-containing diet.

Lambs born the previous year were fed the experimental rations beginning in June. Sheep 1 (Border × Clun cross) had previously been on a high plane of nutrition, that is, good pasture; sheep 2 (Border × Suffolk cross) had been on a low plane of nutrition, that is, stubble. A diet relatively low in magnesium was fed (Table 1) and distilled water supplied for consumption *ad libitum*. The calcium intake was kept at a high level, since an inter-relationship between calcium and magnesium availability is well substantiated. The magnesium content of the diet was higher than had been hoped probably due to the inclusion of mineral salts from tap-water used to wash the fodder cellulose prior to the drying process.

Table 1
Chemical analysis (dry-weight basis)

Feeding stuff	Magnesium (per cent)	Calcium (per cent)	Phosphorus (per cent)
Fodder cellulose	0·16	0·825	0·063
Molasses	0·28	0·94	trace
Flaked maize	0·109	—	0·195
Lucerne hay	0 233	1 97	0·288
$Ca_3(PO_4)_2$	—	38·7	20·2
NaCl	—	—	—

Mineral composition of daily ration during test period
(dry weight basis)
Sheep 1. (Final live weight = 96 lb.)

Feeding stuff	Amount fed (gm.)	Total magnesium (gm.)	Total calcium (gm.)	Total phosphorus (gm.)
Fodder cellulose	460	0·736	3·80	0·29
Molasses	23	0·065	2·15	—
Flaked maize	174	0 190	—	0·84
Lucerne hay	428	0·997	8 44	1·23
$Ca_3(PO_4)_2$	9	—	3·48	1·82
NaCl	9	—	—	—
Total per day		1·988	17 87	3·68

Sheep 2. (Final live weight = 66 lb.)

Feeding stuff	Amount fed (gm.)	Total magnesium (gm.)	Total calcium (gm.)	Total phosphorus (gm.)
Fodder cellulose	276	0·442	2·28	0·174
Molasses	23	0·065	2·19	—
Flaked maize	87	0·095	—	0·170
Lucerne hay	342	0·798	6 75	0·987
$Ca_3(PO_4)_2$	9	—	3·48	1·820
NaCl	9	—	—	—
Total per day		1·400	14 70	3 151
During urea feeding (+ 184 gm. cellulose)		(1·72)	(16·22)	(3·097)

The overall percentage of magnesium in the ration was about 0·18 per cent (dry weight basis) compared with 0·02 per cent (air-dry basis) used by other workers[1] and hypomagnesæmia was not observed in the sheep (Table 2). Feeding stuffs were analysed, after ashing, for calcium[2] and magnesium[3]; total phosphorus determinations on feeding stuffs followed wet oxidation with sulphuric acid/hydrogen peroxide[3]. The same methods were applied directly to blood serum.

Table 2. BLOOD SERUM MAGNESIUM, CALCIUM AND INORGANIC PHOSPHORUS (MGM./100 ML. SERUM)

	Magnesium				Calcium				Inorganic phosphorus			
	A	*B*	*C*	*D*	*A*	*B*	*C*	*D*	*A*	*B*	*C*	*D*
Sheep 1	1·9	2·5	2 1	2·2	11·6	11·0	10·8	10·7	5·6	5·3	4·9	6·1
Sheep 2	2·0	2·3	1·9	2·0	9·9	9·2	9·5	8·9	7·4	7·1	6·2	8 2

A, Basal sample; *B*, low-magnesium ration for 19 days; *C*, low-magnesium ration for 36 days; *D*. low-starch low-magnesium ration with urea for a further 29 days.

A comparison of the diets used in different experiments is of interest. Recently it has been suggested that dietary phytate may inhibit magnesium absorption from the intestine of the rat[4]. The use of corn cobs by McAleese and Forbes in the diet of the lambs and in the bedding[1] would imply a high intake of phytate compared with the small amounts of phytate provided by flaked maize and lucerne hay in the diet listed in Table 1. The competition of phytate for magnesium may exacerbate the already low-magnesium intake, as in the experiments of McAleese and Forbes[1], and so account for the very rapid onset of hypomagnesæmia. Hence the possibility that dietary phytate is a factor in spontaneous hypomagnesæmia needs to be examined, as this competitive effect may occur in the ruminant as well as in the monogastric animal.

A further known factor concerned with magnesium absorption in cows is the level of rumen ammonia[5]. Introduction of large amounts of ammonium acetate and carbonate into the rumen via a fistula reduced both the urinary magnesium excretion and the serum magnesium-levels. Feeding 10 gm. of urea daily, which presumably forms ammonia *in vivo*, did not lead to hypomagnesæmia in sheep on a reduced magnesium intake (Table 2). The rise in serum inorganic phosphorus-level after urea feeding is unexplained; release of phosphate previously bound to phytate would certainly increase the effective phosphorus intake. Flaked maize was omitted from the diet during urea feeding since low-starch rations favour urea toxicity and presumably ammonia production[6].

Only an approximate comparison of the relative amounts of ammonia supplied can be made. Ammonium acetate or carbonate was administered to cows via rumen fistulæ at a rate of about 20–30 gm. ammonia per 100 lb. body-weight[6] compared with about 6–9 gm. ammonia per 100 lb. body-weight given as urea to the sheep.

This evidence reinforces current theories that spontaneous hypomagnesæmia is more complex than a simple nutritional deficiency. Environmental, genetic and endocrine factors may also be concerned in the aetiology of this aberration.

I wish to thank Dr. R. E. Evans for his encouragement and advice.

Bioassay of Ciguatera Toxin

The tropical fish poisoning known as 'ciguatera', which is clearly different from the well-documented tetraodon poisoning, has long been known in the Pacific. Its narrow regional appearance and its variability within a given species of marine fish have been puzzling phenomena. The symptoms associated with ciguatera have been well described, but fundamental knowledge of the toxin is virtually non-existent. The present state of this problem has recently been reviewed by Randall[1].

As the first stage of an investigation aimed at the isolation and identification of the toxic principle, it was necessary to develop a reliable bioassay. The bioassay which had been devised for *Gonyaulax* toxin from shellfish[2] was used and standardized for ciguatera toxin[2] by Halstead and Bunker[3]. A re-investigation of this method in this Laboratory proved that this assay could not be employed with confidence and emphasized the necessity of finding an unambiguous bioassay. As is shown by the results in Table 1 aqueous extraction of toxic fish as described by Halstead and Bunker[3] failed to extract the toxin. It was found that fish or fish extract could be screened for toxicity by feeding raw fish or extract residue mixed with egg to the mongoose (*Herpestes mungo*). This animal exhibits symptoms not unlike those which have been described for humans following ciguatera poisoning. With this qualitative assay it could be shown that ethanol will extract efficiently the toxin from *Lutjanus bohar* (Forskål) collected in the Line Islands and known to be toxic as a result of mongoose feeding. The extraction residue after removal of the ethanol *in vacuo* was injected intraperitoneally into mice. While such an extract would kill mice, so would a similar extract of a non-toxic control fish *Pristipomoides microlepis* (Bleeker), although at a higher dose-level. Satisfactory differentiation of toxic and non-toxic fish could be achieved with a more highly purified extract. The initial ethanolic extract of dried fish flesh was concentrated *in vacuo* and diluted with thrice its own volume of water. The resulting solution was first extracted with light petroleum, then with ether. The bulk of the toxin was found in the ethereal extract. This extract after removal of the solvent when injected intraperitoneally into mice (closed colony Carworth Farms Webster strain, weighing between 19 and 21 gm.) would produce kills at a level of 0·2 mgm./gm. while the ethereal extract of the control fish caused no symptoms at a level of 1·5 mgm./gm. The results of these experiments are included in Table 1.

While sufficient amounts of toxic extract for injection of larger numbers of animals have not been available for a quantitative bioassay, the assay method described above allows reliable recognition of ciguatera toxin. Further research aimed at the isolation and identification of the pure toxin is in progress.

Properties of Vessel Muscle Proteins extracted with Water or Salt Solutions of Low Ionic Strength

EARLIER investigations on the relations of the electrolyte content of organs to hypertension in the rat have shown that only the increase of the potassium content of the vessel wall is characteristic of hypertension[1]. In the carotic strip of cow *in vitro*, potassium produces a rise in tension which lasts so long as the potassium concentration of the bath solution is not altered. Simultaneously with the penetration of potassium into the muscle fibre a rise in tension[2], viscosity and dynamic elasticity modulus[3] occurs. It may be concluded from this that the potassium which entered the muscle fibre discharges certain proteins and so increases the mechanical tension.

Starting from this hypothesis, I have made extracts of relaxed vessel muscles using water or salt solutions of ionic strength either lower than that in the intracellular fluid or equal to it. The muscle of the relaxed cow carotis was separated from other tissues. Then it was minced in a small meat grinder, mixed in a mortar for 10 min. at room temperature with 1·5 c.c./gm. of the chosen solution and finally centrifuged for 15 min. at $22{,}000g$. Extracts so obtained have a high viscosity (η rel. $= 6\cdot02$ at a protein concentration of 1·55 per cent; extract of striated muscle of the same animal η rel. $= 1\cdot61$ at a protein concentration of 1·67 per cent) and show double refraction of flow. After addition of 0·6 *M* potassium chloride (*p*H 7·0) at 15–18° C., they turn into a more or less thixotropic gel after a few seconds. The gelling also takes place, but more slowly, at lower potassium concentrations so long as these exceed that in the intracellular space. Extracts prepared by the same procedure from striated muscle of the cow, rabbit or rat and from smooth muscle of the non-pregnant uterus, bladder and small intestine of the rabbit or the small intestine of the rat do not show the above-mentioned properties. (Extracts of smooth muscle of the bladder and small intestine of the cow show double refraction of flow.) This can be taken as a hint that the vessel muscle contains, besides actomyosin, other structure proteins which are responsible for the permanent tension. We have, therefore, in collaboration with Hamoir, investigated extensively vessel muscle extracts by electrophoresis and ultracentrifugation. The results of these investigations will be reported in another communication.

Our findings clearly demonstrate the presence of two structure proteins. The study of their solubility has enabled us to isolate these proteins and to investigate them separately, as well as the actomyosin which was isolated from the vessel muscle.

Conjugation of *p*-Aminohippurate by the Kidney and Effective Renal Plasma-flow

THE clearance of *p*-aminohippurate has become the standard method for the determination of effective renal plasma-flow, with the assumption that there is no conjugation of *p*-aminohippurate during its passage through the kidney from the blood to the urine. The metabolism of this substance in the body is considered to be similar to that of sulphanilamide which it resembles, namely, acetylation of the *para* amino group. *p*-Acetylaminohippurate and *p*-aminohippurate have similar clearances in the dog and man, so the former may be expected to depress maximal tubular excretion of the latter, but as neither *p*-acetylaminohippurate nor any metabolite in which the *para* amino group is substituted is estimated by the technique used for *p*-aminohippurate, conjugation at sites other than in the kidney should not affect the clearance of the latter. With sulphanilamide, conjugation occurred only in the liver of rabbits and rats, in the liver and spleen in cats, and not at all in the dog (cf. ref. 1). *p*-Aminohippurate itself was not conjugated by rabbit[2] or dog[3] kidney slices *in vitro*, although some conjugation was found with rat[4] and guinea pig[3] kidney slices. From the evidence available, Smith[1] came to the conclusion that conjugation in the kidney did not occur to any significant extent in the species studied (rat, rabbit, cat, dog and man), although it has been suggested by others that conjugation could explain low clearances of *p*-aminohippurate with falling plasma concentrations in man[5].

It will be seen from Table 1 that the conjugation of *p*-aminohippurate does occur to an appreciable extent in the kidney of a number of species; 95 ± 1·3 per cent (22 observations) was recovered after mild acid hydrolysis (100° C. for 30 min., final acid concentration 0·56 *N*). The findings in the rabbit agree with earlier reports, but in the cat only low rates were found in the liver and none demonstrable in the spleen. That this conjugation did interfere significantly with the determination of effective renal plasma-flow was shown in the guinea pig, in which the clearance of free + conjugated *p*-aminohippurate was 1·19 ± 0·05 ($P < 0\cdot01$) (9 determinations) times that of free *p*-aminohippurate on the same samples, with a mean plasma concentration of 0·10 ± 0·015 μmole free *p*-aminohippurate/ml. At this concentration, the calculated values for conjugation and excretion give a value of 1·17 for the above ratio, if the clearance of *p*-aminohippurate is taken to be 13 ml./min. (the mean value of the 9 determinations) and the kidneys weigh 4 gm. each.

The rate of conjugation *in vitro* was maximal at 0·1 μmole/ml., so less error would probably be introduced at higher plasma concentrations, although

Table 1. CONJUGATION OF p-AMINOHIPPURATE *in vitro* BY TISSUE SLICES

Approximately 100 mgm. tissue was incubated for 3 hr. in 2·3 ml. medium containing 30 μmoles sodium acetate in place of an equivalent amount of sodium chloride and 0 4 μmole sodium p-aminohippurate. Values given are means with standard errors with numbers of slices and animals used in brackets

Medium and species	*In vitro* conjugation in μmole/gm. fresh weight/hr.		Estimated *in vivo* excretion of p-aminohippurate by kidney in μmole/gm./hr. at a plasma concentration of 0·1 μmole p-aminohippurate/gm./hr.	Values used for calculation of estimated *in vivo* excretion

Pig	0·18 ± 0·01 (2,1)	0·35 ± 0·02 (2,1)	20	19·5 ml./kgm. body-weight (ref. 8)	1/175 of body-weight
Sheep	0·42 ± 0 05 (3,2)	0·76 ± 0 04 (3,2)	13	500 ml./min. (ref. 9)	225 gm.

No significant conjugation was seen with slices of spleen, lung or heart muscle of any of the species.

the concentration at which maximal tubular excretion is of importance must be kept in mind. At concentrations less than 0·1 μmole/ml., the rate of *in vitro* conjugation fell with the concentration, so the error introduced would probably be similar to that of about 20 per cent found at 0·1 μmole/ml.

For the species which do conjugate p-aminohippurate in the kidney, a truer value for effective renal plasma-flow would probably be obtained by determining the clearance of free + conjugated p-aminohippurate or of p-acetylaminohippurate alone.

Enzymatic Reduction of the Yellow Pigment of *Drosophila*

IT has been demonstrated that the enzymatic conversion of dihydrofolic acid to tetrahydrofolic acid plays an important part in various biochemical reactions[1-3]. It has also been suggested that 7,8-dihydropteridine is reduced to the tetrahydro-level by the enzyme extracted from sheep liver in the presence of reduced triphosphopyridine nucleotide[4]. Recently, the yellow pigment (sepiapterin[5]) of *Drosophila* has been confirmed to be 2-amino-4-hydroxy-6-lactyl-7,8-dihydropteridine[6]. It was therefore thought that the yellow pigment of *Drosophila* might be also converted to tetrahydropteridine by the enzyme extracted from liver.

The dihydrofolic acid reductase from chicken liver was prepared by Futterman's method[7]. It was found that the reductase attacked 2-amino-4-hydroxy-6-lactyl-7,8-dihydropteridine and extinguished both the yellow colour and yellow fluorescence of its solution in the presence of reduced triphosphopyridine nucleotide, but not of reduced diphosphopyridine nucleotide as shown in Fig. 1. The reaction gave a product with a spectrum characteristic of tetrahydropteridine. Thus, this enzyme is capable of reducing the dihydropteridine as well as dihydrofolic acid to 5,6,7,8-tetrahydropteridine with reduced triphosphopyridine nucleotide.

By auto-oxidation, a great portion of the enzymatic reaction product (5,6,7,8-tetrahydropteridine) was converted to a completely dehydrated form having a blue fluorescence, and a small portion was reversed to a partially dehydrated form, namely, the original dihydropteridine, having a yellow fluorescence. The former compound was easily converted to 2-amino-4-hydroxypteridine-6-carboxylic acid by photo-decomposition or oxidation with potassium permanganate. Furthermore, it was decomposed to the same carboxylic acid and aceto-aldehyde by periodate. From these results, it was assumed that the blue fluorescent substance carried the same substituent in the 6-position as that of the original dihydropteridine. Thus, the substance is presumed to be 2-amino-4-hydroxy-6-lactyl-pteridine.

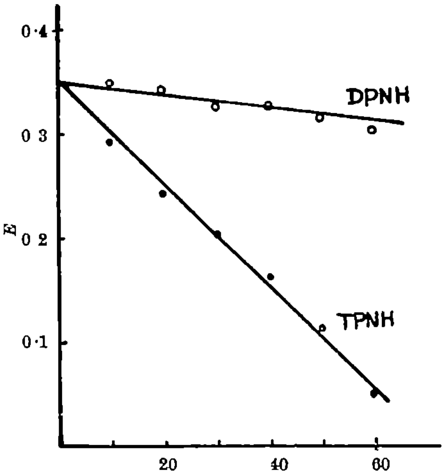

Fig. 1. Effects of reduced tri- and di-phosphopyridine nucleotides on dihydropteridine reductase. Reaction mixture: 10 μgm. 2-amino-4-hydroxy-6-lactyl-7,8-dihydropteridine; 40 μgm. reduced tri- or di-phosphopyridine nucleotide; 45 mM phosphate buffer pH 6·0; 0 3 ml. chicken liver enzyme fraction. Total volume 3 ml. Temperature of incubation 37° C. A spectrum characteristic of the dihydropteridine at 410 mμ

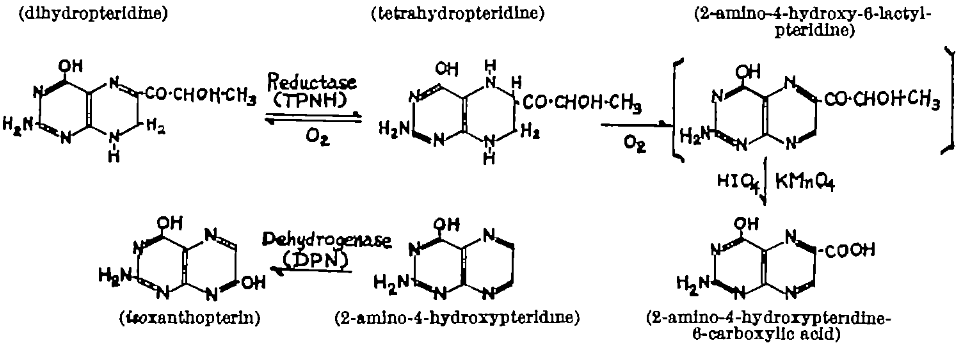

Fig. 2. A possible metabolic pathway of pteridines in *Drosophila*

The product in the enzymatic reaction mixture contained a considerable amount of *iso*xanthopterin that was not present in the original reaction mixture. I confirmed that the chicken liver extract was capable of converting 2-amino-4-hydroxypteridine to *iso*-xanthopterin. Therefore, it is suggested that 2-amino-4-hydroxypteridine was derived from the decomposition of tetrahydropteridine and converted enzymatically to *iso*xanthopterin.

In the presence of reduced triphosphopyridine nucleotide, the partially purified enzyme of *Drosophila* was capable of reducing the dihydropteridine to the tetrahydropteridine from which 2-amino-4-hydroxy-tryptamine can be derived by auto-oxidation. It has been shown that the latter can be converted to *iso*xanthopterin by pteridine oxidase[8] or dehydrogenase[9] extracted from *Drosophila*. These observations suggest a metabolic pathway of pteridines in *Drosophila* such as is shown in Fig. 2.

Cardiac Effects of Streptolysin O in Rabbits

Although several of the known streptococcal enzymes or toxins have been suspected of playing a part in the pathogenesis of the heart lesions in rheumatic fever, a number of reports have suggested that streptolysin *O* may be of some importance in the causation of focal cardiac damage in experimental animals. Kellner *et al.*[1] have demonstrated that the rabbit heart *in vitro* is extremely sensitive to this substance. Schwab *et al.*[2], among others, showed that rabbits pre-treated with certain streptococcal factors developed a high incidence of focal cardiac lesions on subsequent injection of streptolysin *O* containing filtrates. These investigations were carried out with impure preparations of unknown complexity.

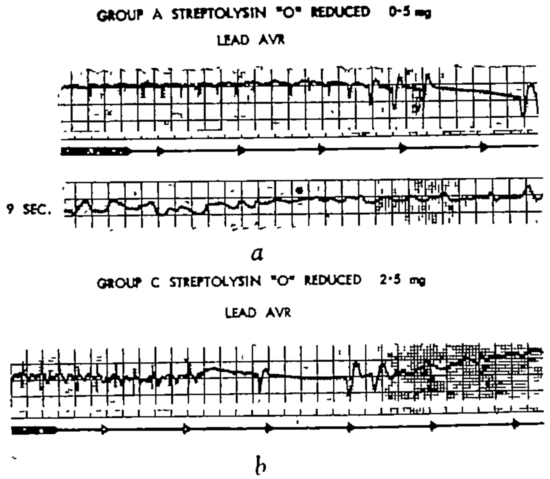
Previous reports from this laboratory have described the value of agar precipitin analysis in the study of human streptococcal infections[3-4]. In the course of this work, very highly purified streptolysin *O* preparations were obtained, using a combination of continuous-flow electrophoresis and column chromatography on calcium phosphate (hydroxylapatite) gels. Sufficient amounts of similar preparations from a group *A* and group *C* streptococcal strain have been separated in order to study their effects on intravenous injection in rabbits. Such observations were made in an attempt to translate the above-cited findings to the *in vivo* environment. Although the final fractions were not as free of contamination immunologically as those obtained previously[5], they were both extremely potent. The group *A* fraction revealed about 160,000 hæmolytic units/mgm. protein, and the group *C* about 60,000 units/mgm. Both contained small amounts of diphosphopyridine nucleotidase, and the group *A* showed traces of a third component immunologically. The group *C* material, only, contained appreciable amounts of apparently non-protein substances in the lyophilized powder (about 40 per cent).

The cardiotoxic effects of intravenously injected streptolysin *O* in rabbits were studied electrocardiographically in all instances. In a number of cases, femoral artery blood pressures and electroencephalograms were also recorded. Albino rabbits from a single dealer (2·6–3·2 kgm.) of either sex were used. The streptolysin solutions, and all others, were made in 0·1 *M* sodium phosphate at *p*H 7·2. Activation of the streptolysin was carried out by adding a neutralized 1-cysteine hydrochloride solution to a final concentration of 10 mgm./ml., and incubating at 30° C. for 10 min., following which it was kept in an ice-bath.

The *LD*50 of the group *A* activated (reduced) streptolysin was approximately 0·15 mgm. dry weight of the lyophilized powder, while that of the group *C* material was 0·75 mgm. dry weight (about 0·45 mgm. protein). A total of 50 rabbits was used for these assays.

Following injection, with few exceptions, death ensued within 5 min., or less, associated with convulsions and respiratory standstill. It was observed that considerable electrocardiographic changes always preceded the convulsions, and could be produced within as short a time as 3 sec. with 3–4 *LD*50. The injection itself took approximately 2–3 sec. Examples of the very rapid electrocardiographic changes are shown in Figs. 1*a* and *b*. There was immediate transition from normal sinus rhythm to ventricular arrhythmia, followed by electrocardiographic silence.

With smaller but still lethal doses (1–2 *LD*50) the reaction often took somewhat longer to develop. An



GROUP A STREPTOLYSIN "O" REDUCED 0·5 mg

Fig. 1. Electrocardiographic tracings of rabbits receiving intravenous injections of reduced activated streptolysin *O* in several multiples of the *LD*50 dose. The injection period is marked on the 1-sec. time interval record. *a*, Group *A* streptolysin *O*, 0·5 mgm. dry weight/0 5 ml. (Lower strip tracing starts 9 sec after the injection was completed.) *b*, Group *C* streptolysin *O*, 2·5 mgm. dry weight/1 0 ml.

example of the electrocardiographic changes occurring in a rabbit receiving such a dose of the group *A* preparation is shown in Fig. 2. Within 25 sec., unifocal ventricular rhythm with ST segment depression occurred. Within 125 sec., typical ventricular arrhythmia was seen, and within 224 sec., ventricular tachycardia was soon followed by ventricular fibrillation. In all instances, the motor convulsions occurred without electroencephalographic convulsive discharges.

In nine of thirteen cases, non-lethal doses of the fractions produced temporary electrocardiographic changes, such as ST—T depression, supraventricular or ventricular extrasystoles, or bigeminal rhythm, but these were erratic in occurrence. Sometimes they lasted intermittently at least as long as 18 hr.

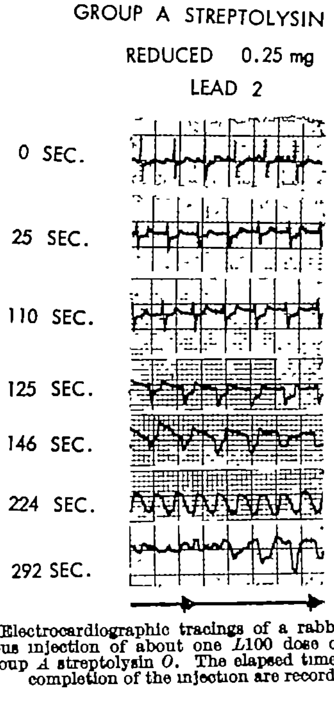

Fig. 2. Electrocardiographic tracings of a rabbit receiving an intravenous injection of about one *L*100 dose of reduced activated group *A* streptolysin *O*. The elapsed times following the completion of the injection are recorded

When lethal doses were given, the blood pressure dropped rapidly to less than 25 mm. mercury. This fall occurred either following or prior to the electrocardiographic changes, and was later followed by electroencephalographic silence.

Evidence that the lethal effects were due to streptolysin *O* was obtained in several ways, in addition to the high degree of apparent purification immunologically. Much larger doses of the reversibly oxidized inactive form were required to bring about lethal effects, 1 mgm. dry weight of the group *A*, and 6·5 mgm. of the group *C* preparations being required. The time required for death was substantially longer with the oxidized form as compared to equivalent amounts of the reduced. It is likely that the streptolysin may be gradually reduced to activity *in vivo* in view of the known oxidation-reduction potential of tissues[6].

Cholesterol, a potent inhibitor of the hæmolytic activity of streptolysin *O* (ref. 7), protected rabbits against the lethal and electrocardiographic effects, when an aqueous suspension was mixed with the challenge dose. Diphosphopyridine nucleotidase has been shown to be unaffected by cholesterol, and by reduction with cysteine[8].

Numerous control experiments with cysteine, and different streptococcal fractions previously isolated[5], including deoxyribonuclease *B*, streptococcal proteinase, C-carbohydrate protein complex[9], and an antigen possibly related to scarlet fever toxin, failed to produce similar electrocardiographic effects. *Shigella paradysenteriae* Flexner type III endotoxin also did not show any such reactions.

These observations showed that streptolysin *O* from a group *A* and a group *C* streptococcal strain may kill rabbits extremely rapidly when given intravenously. Extensive electrocardiographic and blood pressure changes were observed preceding death. With several multiples of the lethal dose, cessation of cardiac activity was noted within 3–5 sec. following the injection. The findings presented here support the speculation that streptolysin *O* may be the factor causing cardiac lesions *in vivo*, as a result of repeated streptococcal infections in experimental animals (for example, ref. 10). Their relation to the pathogenesis of human rheumatic fever remains to be determined.

These investigations were supported by research grants from the Office of Naval Research, the Life Insurance Medical Research Fund, and the New York Heart Association.

Levels of Serotonin during Convulsion and the Effect of Reserpine

IN view of the contradictory reports[1-3] with respect to changes in the 5-hydroxytryptamine (5-HT) levels of the mammalian central nervous system during convulsion, this problem was re-examined in rats in which convulsion was induced by intraperitoneal injection of fluoroacetate or 'Metrazol'. The former convulsant was particularly preferred because, unlike the convulsive agents generally employed, its action can be related to specific biochemical events, that is, blocking of the citric acid cycle[4] with concomitant changes in certain amino-acid[5]- and ammonia[6]-levels of the central nervous system.

The serotonin content of brain, small intestine and spleen of rats treated with convulsants, with or without simultaneous administration of reserpine, was compared with control animals. The solution of reserpine for intraperitoneal injection was prepared by dissolving reserpine crystals (100 mgm.) in 0·1 ml. of concentrated formic acid, 2·5 ml. propylene glycol, 2·5 ml. absolute alcohol and water to make the volume 20 ml. (Formate was used instead of glacial acetic acid to avoid the competition of acetate with fluoroacetate.) The animals which did not receive reserpine received only intraperitoneal injection of reserpine solvent. The animals were killed at 60 min., with the onset of convulsion at 30 min. The amount of fluoroacetate injected was greater than the *LD*50, 5 mgm./kgm. for rats, in order to ensure the severity and the recurrence of seizures between onset and time of killing.

Statistical analysis of the values in Table 1 indicates that fluoroacetate-produced convulsion does not cause an increase of serotonin-level in the brain or in the other organs analysed. Administration of reserpine did not produce any delay in the onset of convulsions or in the incidence of seizures. However, it depleted serotonin within 1 hr. by 78 per cent from the brain of convulsing animals, but not from the spleen or the intestine, a pattern similar to that produced by reserpine in non-convulsing rats[8]. Administration of reserpine did not alter the fluoroacetate-produced citrate accumulation in the brain to any degree of statistical significance. In another series of experiments 'Metrazol' (60 mgm./kgm.) was administered intraperitoneally alone and with reserpine. 'Metrazol', like fluoroacetate, had no effect on the 5-HT values of the brain of convulsing rats killed 1 hr. after administration of the drug. Again, convulsions produced by 'Metrazol' had no effect on the release of 5-HT by reserpine from the brain.

Table 1. EFFECT OF CONVULSION ON 5-HYDROXYTRYPTAMINE CONTENT OF SOME RAT TISSUES AND THE INFLUENCE OF RESERPINE. Sprague–Dawley male rats (350–400 gm.) received intraperitoneally sodium fluoroacetate (8 mgm./kgm.) and reserpine (6 mgm./kgm.) as indicated. 5-Hydroxytryptamine was determined by the spectrophotofluorometric method (ref. 7) and the citrate, as described elsewhere (ref. 4). Numbers of animals indicated in brackets

Group	5-Hydroxytryptamine (μgm./gm. wet tissue) Brain	Spleen	Small intestine	Citrate (μgm./gm. wet tissue) Brain
Control (10)	0·41 ± 0·03*	2·02 ± 0·22	2·08 ± 0·30	19 ± 1·3
Fluoroacetate (10)	0·48 ± 0·03	1·78 ± 0·27	2·11 ± 0·36	151 ± 10
Fluoroacetate + reserpine (10)	0·11 ± 0·05	1·90 ± 0·28	2·30 ± 0·30	119 ± 13
Reserpine (5)	0·12 ± 0·05	2·34 ± 0·67	3·00 ± 0·39	
'Metrazol' (6)	0·40 ± 0·02	2·17 ± 0·18	3·43 ± 0·31	
'Metrazol' + reserpine (6)	0·25 ± 0·05	2·40 ± 0·25	3·16 ± 0·26	

* *S.E.*

It can safely be stated that there is no statistically proved evidence to demonstrate that fluoroacetate, and, under the conditions of our experiments, 'Metrazol', have any effect on the 5-HT levels of rat brain.

Enzymic Release of Sialic Acid and Inactivation of Human Menopausal Gonadotropin

IT has been shown that the biological activity of chorionic and pituitary gonadotropins is lost when the hormone materials are treated with influenza virus or with receptor-destroying enzyme[1-3]. This enzyme has been recognized as neuraminidase[4], and the loss of biological activity of gonadotropins on treatment with the above catalytic agents was accompanied by the release of sialic acid. It seemed desirable to investigate the effect of neuraminidase on the chemical composition and biological activity of a purified preparation of human menopausal gonadotropin[5,6].

The relative potency of the preparation used, in terms of human menopausal gonadotropin-24, was 100 when tested by the augmentation of uterus weight in 3-week-old female mice. It contained 7·8 per cent of sialic acid, determined by the diphenylamine reaction[7] and expressed as N-acetylneuraminic acid. Heating at 100° C., *p*H 2, for 1 hr. destroys the activity and quantitatively removes sialic acid, but it is possible that other bonds (sugar, amino-acid) were broken.

10 mgm. of human menopausal gonadotropin preparation, dissolved in 10 ml. *M*/15 phosphate buffer, *p*H 6·3, was incubated with about 30,000 units of neuraminidase (receptor-destroying enzyme, Behringwerke) at 35° C. After 24 hr. the solution showed a loss of gonadotropic activity of 80 per cent, as compared with a control kept under the same conditions but without the receptor-destroying enzyme. Reaction mixture was then dialysed twice against 10 vol. of water at 0° for 48 hr. About 60 per cent of initial sialic acid was found in the dialysate. After concentration, the dialysate was applied to a column of 'Dowex 2' 200–400 mesh (20 × 0·8 cm.), equilibrated in 0·1 *M* formic acid[8]. The effluent was collected in 3-ml. fractions which were analysed for their sialic acid content. Elution with 0·3 *M* formic acid yields two peaks (fractions 13–19 and 24–29).

Paper chromatography (*n*-butanol / pyridine / 0·1*N* hydrochloric acid, 5 : 3 : 2) showed that the two peaks contained the same component which was identified as N-glycolylneuraminic acid. Release of glycolic acid, after hydrolysis by *N* sulphuric acid, confirmed this result[9].

Although the human menopausal gonadotropin preparation was not pure, the following conclusions may be drawn from the experimental results: (*a*) human menopausal gonadotropin contains sialic residues which are accessible to neuraminidase; (*b*) enzymic release of the sialic acid residues reduces the biological activity of human menopausal gonadotropin by 80 per cent or more. Bound sialic acid is an essential part of the molecule.

Seasonal Variation in Blood Pressure in Man

SEVERAL of man's bodily functions, such as thyroid activity, are known to show a characteristic seasonal pattern; but in general such seasonal variations have received less attention in man than in many other animals. In particular, seasonal trends in blood pressure do not seem to have been measured hitherto.

The data presented here were derived from measurements on 56 middle-aged men who had been observed for 1–3 years at a clinic for ischæmic heart disease. Most had suffered cardiac infarction, but for all of them at least two months had elapsed since the acute illness and during the period of observation they were in a clinically stable state. There were three observers, but as a rule each subject's blood-pressure measurements had all been taken by the same observer. All measurements were made in a comfortably warm room after a period of rest and using standard instruments.

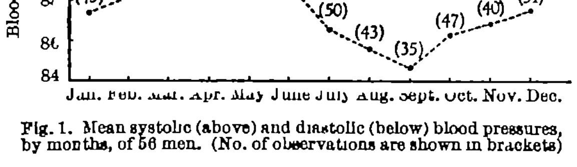

Fig. 1. Mean systolic (above) and diastolic (below) blood pressures, by months, of 56 men. (No. of observations are shown in brackets)

The results are shown in Fig. 1, where mean systolic and diastolic pressures have been plotted by months; the technique of grouped means has been followed; the value at each month represents the mean of the values for that and the two adjacent months. There is a clear seasonal trend, with a peak covering the spring and a trough in the late summer.

This pattern is quite different from that of ischæmic heart disease morbidity and mortality, which follow the reciprocal of air temperature, namely, a peak in January and February and a lower level throughout the late spring and summer.

Relationship between Urinary Hyaluronidase and Diuresis

In a recent communication, Berlyne[1] states that he was unable to corroborate my results[2] on the relationship between the hyaluronidase activity of the urine and diuresis.

(1) Berlyne believes that my method is unsuitable for quantitative assay of urinary hyaluronidase, as I did not take into account the drop of substrate viscosity before the first reading. But the determination of enzyme activity by the method of Swyer and Emmes[3], used by me, does not depend on the initial substrate viscosity. The modified method of McLean and Hale[4], used by Berlyne, has no advantage over mine.

He thinks that my results are not precise enough because I did not take into account the electrolyte effect. But in practice I did take it into consideration, and some of my experiments were performed on samples of urine previously dialysed. On the removal of electrolytes, hyaluronidase activity somewhat increases. But the correction introduced by dialysis does not alter the main relationship and curves of dialysed urine, as well as of electrolyte-containing urine run in parallel[5].

(2) Berlyne believes that I was wrong when giving the results as the fermentation activity of the urine in arbitrary units. In his opinion, the results should be expressed by the amount of the enzyme excreted per minute. I cannot agree with this.

The urinary hyaluronidase is produced by renal cell secretion under the action of antidiuretic hormone. The enzyme performs a specific function in the kidney. It depolymerizes hyaluronic structures of the tubules, and this provides the conditions for antidiuretic reaction. The appearance of hyaluronidase activity in urine should not be regarded as a process of excretion. This phenomenon is merely a side-effect of the antidiuretic hormone enabling one to verify the mechanism of the hormone action.

From the above point of view, there is no reason to express the results as the product of the enzyme concentration (irrespectively of any units) by the volume of urine, as it is done for estimating the excretion of substances removed by the kidney. As this operation has no physiological meaning in this case, it becomes purely arithmetical and completely distorts the essence of the phenomenon under study.

(3) The probability of my physiological interpretation of the phenomenon in question was investigated in two series of experiments. In one (jointly

with V. Vasiljeva and J. Natochin), dogs were decerebrated, the cut running behind the tuber cinereum. The hypophysis was removed and the kidney denervated. To maintain a steady diuresis-level, mannitol solution was administered intravenously. A few urine samples were collected for 1 hr. Then a large dose of 'Pitressin' was injected, and urine was collected for another hour.

On the removal of antidiuretic hormone-producing structures, urine, unlike normal dog urine, does not exhibit hyaluronidase activity during osmotic diuresis. Under the hormone action, the enzyme appeared in urine in spite of the fact that urine flow increased.

In another series of experiments (jointly with L. Ivanova) on dogs with a permanent fistula of the ureter, the animals were deprived of water for 24 hr. Urine collected during hydropeny revealed high hyaluronidase activity. The second urine sample was collected after the dog was allowed to drink water and then diuresis exceeded 1 ml. per min. In this sample no enzyme was found. Then urine was concentrated in vacuum. Thus it was artificially reduced to the volume corresponding to the rate of natural urine flow during dehydration. Yet even then the urine did not acquire hyaluronidase activity. Thus the loss of enzyme at water diuresis cannot be accounted for by the dilution alone, though this factor certainly exercises its usual effect.

(4) The difference between osmotic and water diuresis is particularly distinct if the corresponding correction eliminates the dilution effect. I did this in the following way. Urine samples collected at different levels of diuresis were dialysed and then concentrated in vacuum to the volumes corresponding to a urine flow of 0·2 ml./min. In this way I obtained the results shown in Fig. 2 of my communication in *Nature* to which Berlyne refers. All the points on the curve, both for water and osmotic diuresis, represent urine activity under reduced conditions. Hence the results are not complicated either by dilution or by electrolyte effect. Considering the process under such constant conditions, I arrived at the conclusion that secretion of hyaluronidase by renal cells decreases during water diuresis, but it remains at a constant level during osmotic diuresis.

By direct estimation of hyaluronidase activity of urine collected during osmotic diuresis without any correction for dilution, I certainly found that activity drops as the flow of urine increases.

[5] Ivanova, L. N., *Bull. Exp. Biol. Med.*, **45**, 22 (1958) (in Russian)

I AM grateful for the opportunity afforded by Prof. Ginetzinsky's letter to clarify certain points in my previous communication[1] which I had omitted as they are dealt with at length elsewhere[2]. I hope to resolve some of the problems mentioned by Prof. Ginetzinsky point by point.

(1) It has been shown by McLean and Hale[3] and confirmed by me[1,2] that the ionic strength of the hyaluronic acid – buffer – hyaluronidase system must be kept constant if quantitative measurement of hyaluronidase is to be achieved. In a system containing constant amounts of hyaluronidase and hyaluronic acid, as the ionic strength of the medium is increased from 0 to 0·3 *M* the apparent hyaluronidase activity changes from 0 to 90 units (Fig. 3 of ref. 3). Thus it is essential to control electrolyte concentration carefully if quantitative results are to be obtained with urine. I chose to keep ionic strength constant by electrometric estimation and addition of salt in appropriate amounts rather than use dialysis, where adsorption of hyaluronidase might take place on to the dialysing membrane. The method used is published in detail elsewhere[2].

(2) It seems reasonable to express urinary hyaluronidase findings in terms of excretion per unit time, as is the practice with other urinary solutes. If one accepts the statement that hyaluronidase appears in the urine "merely as a side-effect of the antidiuretic hormone" and "not as a process of excretion" in order to justify the use of hyaluronidase concentration as opposed to excretion per minute, then there is little point in measuring hyaluronidase excretion (either per ml. or per min.) as evidence for or against Ginetzinsky's hypothesis of the role of hyaluronidase in the urine-concentrating mechanism. If one plots urinary hyaluronidase concentration against urine flow, one obtains a similar graph to that which would be obtained by plotting creatinine concentration against urine flow; that is, the lower the flow, the higher is the concentration of both hyaluronidase and creatinine. Nobody would suggest that creatinine is implicated in the antidiuretic hormone mechanism of urine concentration, yet Ginetzinsky used evidence of this type to suggest that hyaluronidase is instrumental in the antidiuretic hormone mechanism for urine concentration.

(3) I am not familiar with the decerebrate hypophysectomized dog preparation and am unable to comment on this experiment without knowing details of urine electrolyte concentration, urine flow-rate, etc. In Ginetzinsky's article (ref. 4, Fig. 2) he shows that the dog in osmotic diuresis in four out of five results has urine flows of 1·5 ml./m.^{2}/min. or less. These are very small for adequate mannitol osmotic diuresis, and are not strictly comparable with my results in humans, where urine flows up to 9·5 ml./min. were reached.

The fact that Prof. Ginetzinsky in only some experiments dialysed and then reduced to constant volume indicates that he realized the need for measuring hyaluronidase excretion per min. Unfortunately, he did not do this in all experiments; hence his results are not uniformly expressed and therefore direct comparisons cannot be made.

Since my initial communication I have extended the number of observations on humans in water

Table 1

Urine (ml./min.)	Osmolality of urine (mOsmols/kgm.)	Hyaluronidase (units/ml.)	Hyaluronidase excretion per min.
3·42	240	0 6	2·04
4·2	133	0 25	1 1
4 75	154	0·45	2 1
5 6	162	0·38	2·1
6 23	91	0·75	4·7
6·7	104	0·45	3 0
7·8	94	0·125	0·98
8·06	103	0·26	2·1
9·55	84	0 12	1·2
10·7	55	0 12	1·3

diuresis in the range 3·42–10·7 ml./min., as shown in Table 1.

It will be seen that I found detectable amounts of hyaluronidase even at high urine flows in water diuresis whereas Ginetzinsky does not. The most obvious explanation for this discrepancy is that I was using a more sensitive method, and one which does not involve loss from dialysis.

HISTOCHEMISTRY

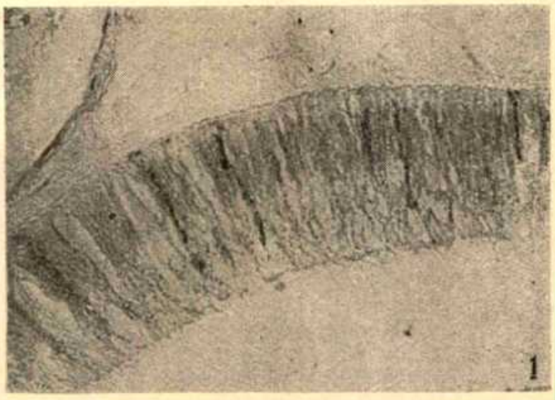
Presence of Enterochromaffin Cells in the Gut of Amphioxus

Histochemical evidence has been found for the presence in the gut of amphioxus of argentaffin cells, which do not appear to have been described formerly; because of their localization and their histochemical characteristics, they can be considered to be of enterochromaffin type, shown to be present in other groups of Chordata (by Vialli and Erspamer[1] for all vertebrates, except Cyclostomata and Teleostea, and by Lison[2] for Ascidians).

The histochemical characteristics of typical enterochromaffin cells are well established[1], namely, positive reaction in the chromaffin, argentaffin and diazonium in alkaline solution tests. Other staining methods (non-histochemical) are also suitable for detection of enterochromaffin cells, based on their acidophilia and argyrophila. Moreover, Jacobson[3] observed later that the specific substance fixed in the granules of enterochromaffin cells is removed by a hot pyridine–methanol mixture. Finally, quite recently, Pearse in his book[4] presents as characteristic of the enterochromaffin cells five major histochemical tests (chromaffin, argentaffin, diazonium, indophenol and Gibbs's reactions) and other subsidiary ones, including the autofluorescence, the Schmorl ferric–ferricyanide reaction and the Pearse thioindoxyl reaction.

For the present work, four specimens of *Branchiostoma lanceolatum* Pallas, 30–50 mm. long, after having been fixed in 10 per cent formol-saline and embedded in paraffin, were cut transversely to provide a series of sections of 6μ thickness.

In the gut, some cells were found to be strongly positive by the Masson–Hamperl argentaffin reaction. The argyrophil methods (particularly the Bodian reaction) gave also positive results, corresponding to those of the former reaction as regards number and localization of the cells. Positive results were obtained, however, with very faint contrast compared to the background, after the chromaffin reaction, the Gibbs indophenol reaction, the Lillie diazo–safranine reaction at *p*H 9·4 and the Schmorl ferric–ferricyanide reaction. No positive reaction was found with other diazo-coupling methods (with sulphanilic acid and stabilized diazonium salts), the Pearse thioindoxyl reaction or autofluorescence; after treatment with a pyridine–methanol mixture at 60° C. for five days, the sections did not stain with any of the methods mentioned above.



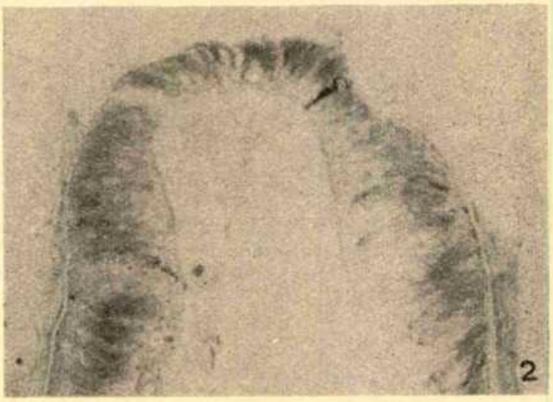


Fig. 1. Left wall of mid-gut; Masson argentaffin reaction. Epithelial ciliated cells are closely packed; some narrow enterochromaffin cells are seen. (× 500)

Fig. 2. Dorsal groove of hind-gut; Masson argentaffin reaction. Epithelial ciliated cells are less packed and narrow: one enterochromaffin cell is clear, but others are seen only with few granules in focus

The cells under examination are very slender in shape, occupying the whole height of the intestinal epithelium, and are slightly larger at the base, where the specific granules may be more evident. These cells are usually isolated, and not more than 5–8 occur in each section.

The enterochromaffin cells do not occur in the anterior tract of the digestive tube; they occur in the posterior part of the mid-gut on the left wall and the dorsal zone, to continue only dorsally in the ilio-colon ring and in the hind-gut. They are localized in the strongly ciliated tracts, that is, in the lateral ciliated tract of the posterior part of the mid-gut and the dorsal ciliated tract in the ilio-colon ring and in the hind-gut (the terminology corresponds with that of Barrington[5]). This peculiar distribution requires further study in connexion with the morphogenetic and functional interpretation.

I have not been able to find evidence for all the ordinary histochemical characteristics already mentioned for enterochromaffin cells of vertebrates, in which the presence of 5-hydroxytryptamine (enteramine) has been proved[6,7]; nevertheless, the failure of some tests may depend on decreased sensibility of the reactions, as has been confirmed in other cases, or on decreased contrast of the stain compared with the background. This problem was recently discussed by Vialli[8] in connexion with staining methods for enterochromaffin cells.

A more extensive investigation of this kind on which I am engaged should contribute to a unified interpretation regarding the biological meaning of the enterochromaffin system and the metabolism of 5-hydroxytryptamine, at least within the Chordata.

HÆMATOLOGY

Fibrinolytic Activities present in Human Blood Platelets

BLOOD platelets have been shown to contain antiplasmin activity[1-3]. The experiments to be described in this communication demonstrate that blood platelets interfere in still another way in fibrinolysis. The fibrinolytic activity brought about by streptokinase comprises two steps[4]: (1) activation of a proactivator which could be identical in man with plasminogen; (2) transformation of plasminogen to plasmin by the activator, resulting from reaction (1).

When human blood platelets are added in increasing concentrations to a test system composed of streptokinase and bovine fibrinogen, clotted by addition of thrombin–calcium solution, a progressive increase of fibrinolytic activity is observed. This was demonstrated by each of the following three methods: estimation of clot lysis-times, thrombelastographic recordings and the fibrin plate method according to Astrup and Müllertz[5]. Table 1 represents the results obtained with clot lysis-time determination.

Table 1. INFLUENCE OF HUMAN BLOOD PLATELETS ON STREPTOKINASE-INDUCED LYSIS OF BOVINE FIBRIN

Concentration of blood platelets in the added suspension	Clot lysis time
5,000,000/mm.^{3}	15 min.
2,500,000/mm.^{3}	21 min.
1,000,000/mm.^{3}	40 min.
500,000/mm.^{3}	85 min.
100,000/mm.^{3}	18 hr.
Isotonic sodium chloride (control)	more than 48 hr.

0·1 ml. blood platelets suspension is mixed with 0·1 ml. streptokinase solution (1,000 U./ml.) and added to 0·5 ml. bovine fibrinogen (1 gm. per cent). The mixture is clotted by addition of 0·2 ml. Thrombin 20 U./ml., dissolved in *M*/20 calcium chloride. Determination of clot lysis-time at 37° C.

The bovine fibrinogen ('Rinderfibrinogen' from Behring-Werke, Marburg/Lahn, Germany) used as substrate contained large quantities of plasminogen but was nearly free of proactivator activity. In control experiments where blood platelets were substituted by isotonic sodium chloride solution, lysis did not occur within a 24-hr. period. The thrombin ('Test Thrombin' from Behring-Werke) used was found to be void of any appreciable contamination with plasminogen or proactivator. The streptokinase was a highly purified preparation, kindly supplied by Behring-Werke. Veronal buffer (*p*H: 7·35, μ: 0·154) according to Owren, was used for dissolving fibrinogen, streptokinase, urokinase and plasmin. Blood platelets were suspended in isotonic sodium chloride solution.

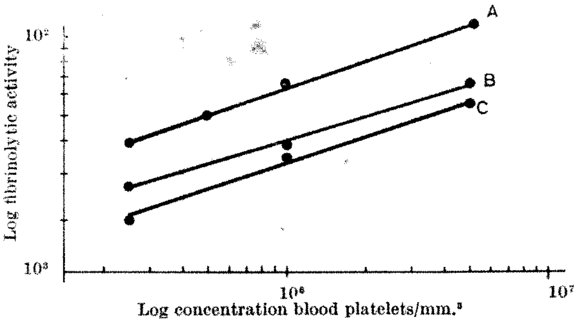

Fig. 1. Influence of washing platelets on their promoting effect on streptokinase-induced lysis of bovine standard fibrin. Results of determinations of fibrinolytic activity by the fibrin plate method. Double logarithmic graph. Abscissa: concentration of blood platelet suspension tested; ordinate: fibrinolytic activity as measured by the product of the two diameters of the lysed zones. The tested platelet suspension is mixed with an equal volume of streptokinase solution (5,000 U./ml.); 0·03 ml. of this mixture is placed on the surface of the plate. Curve *A*, blood platelets washed once with isotonic sodium chloride solution; curve *B*, platelets washed 5 times; curve *C*, platelets washed 10 times

The blood platelets tested in our experiments had been prepared by several techniques. Successively, lyophilized human blood platelets[6] and human blood platelets isolated from sequestrene, citrated or A.C.D. plasma were used. They all had a similar enhancing effect on streptokinase-activated lysis of bovine fibrin.

In contrast to the influence on streptokinase-induced lysis of bovine fibrin, human blood platelets had a clearly inhibiting effect on urokinase (kindly supplied by Dr. J. Ploug, Leo Pharmaceuticals, Ballerup, Denmark) or plasmin (the chloroform-activated bovine fibrinolysin, kindly supplied by Dr. E. Loomis, Parke Davis and Co., Detroit) activated lysis.

Further work showed that washing platelets resulted in a gradual weakening of the promoting effect on streptokinase-activated fibrinolysis. After ten washings, however, there was still an appreciable residual activity (Fig. 1). The antiplasmin effect, on the other hand, was only slightly diminished by the washing procedures.

Heating of platelets at 80° C. for 15 min. completely destroyed the above-described lysis-promoting activity. Instead of an enhancing an inhibiting effect on streptokinase-induced lysis was observed (Table 2). The antiplasmin activity was not diminished by this heating procedure.

Our results, which will be published in detail elsewhere, demonstrate that blood platelets, on addition of streptokinase, form an activator of plasminogen. This can be explained by the assumption that blood platelets contain so-called proactivator activity. The presence of plasminogen in blood platelets seemed to be ruled out as a possible explanation for the observed facts. Indeed, no fibrinolytic activity could be produced when mixtures of blood platelets and streptokinase were tested on heated fibrin plates, in which the plasminogen had been destroyed.

Table 2. INFLUENCE OF HEATING PLATELETS ON STREPTOKINASE-INDUCED LYSIS OF BOVINE FIBRIN

Concentration of lyophilized platelets in the added suspension	Clot lysis-time	
	Unheated platelets	Heated platelets (15 min. at 80° C.)
10 mgm./ml.	8 min.	120 hr.
2·5 mgm./ml.	18 ,,	72 ,,
0·625 mgm./ml.	42 ,,	46 ,,
Isotonic sodium chloride (control)	39 hr.	39 ,,

0·1 ml. lyophilized human blood platelets are mixed with 0·1 ml. streptokinase solution (5,000 U./ml.) and added to 0·3 ml. bovine fibrinogen (2 gm. per cent). This mixture is clotted by addition of 0·1 ml. thrombin (20 U./ml.) dissolved in *M*/10 calcium chloride. Determination of clot lysis-time at 37° C.

The investigation of the influence of washing and heating showed that the platelet proactivator is to be distinguished from the blood platelet antifibrinolysin. These two activities cannot be caused by an identical platelet substance. The lysis-promoting property of blood platelets completely masks their antifibrinolytic effect in the case of streptokinase-activated lysis. Whether the proactivator activity of blood platelets is to be attributed to an intrinsic or adsorbed platelet component cannot be stated with certainty at present. In any event, ten-fold washing of blood platelets does not extinguish its effect.

These observations were confirmed in relation to fibrinogenolysis by determination of the so-called antithrombin VI activity[7], arising in a system composed of bovine fibrinogen, streptokinase and blood platelets. It was established that the apparent amount of antithrombin VI was directly proportional to the concentration of blood platelets present in the test system.

It seems highly probable that the proactivator activity of human blood platelets plays an important part in the spontaneous fibrinolytic activity of human blood. Indeed, the latter is known to be chiefly caused by an activator of plasminogen, probably formed by activation of proactivator[8].

Precipitating Factor for Aggregated γ-Globulins in Normal Human Sera

SERA of patients with rheumatoid arthritis often form a precipitate when mixed with aggregated γ-globulins[1]. The precipitate consists of a 19 *S* γ-globulin ('rheumatoid factor'), variable amounts of 7 *S* γ-globulin and more rapidly sedimenting aggregates of γ-globulin[2]. The latter are known to be anti-complementary[3]. While studying a test for rheumatoid arthritis[4], it was found that normal human sera also form a precipitate with aggregated γ-globulins, although more slowly and less abundantly.

Aggregated γ-globulins were prepared by treating 1 per cent solutions of Cohn's human fraction II in 1/15 molar phosphate buffer, *p*H 7, containing 1 : 10,000 merthiolate, with 0·25 per cent formalin for two weeks at room temperature, followed by dialysis in the cold against the same buffer without formalin. This resulted in marked opalescence of the solutions. Ultracentrifugal analysis showed the presence of large aggregates. When mixed in capillary tubes with an approximately equal amount of human serum, these preparations yielded a precipitate after incubation for 2 hr. at 37° C. and for 18 hr. at 4° C. Sera of 200 patients, aged 5–80, with various diseases, and of 80 adolescent and adult healthy subjects, were found to react. Exceptions were found only in the sera of the 10 new-born babies tested, which showed no, or minimal, precipitate, although their mothers' sera formed a heavy precipitate.

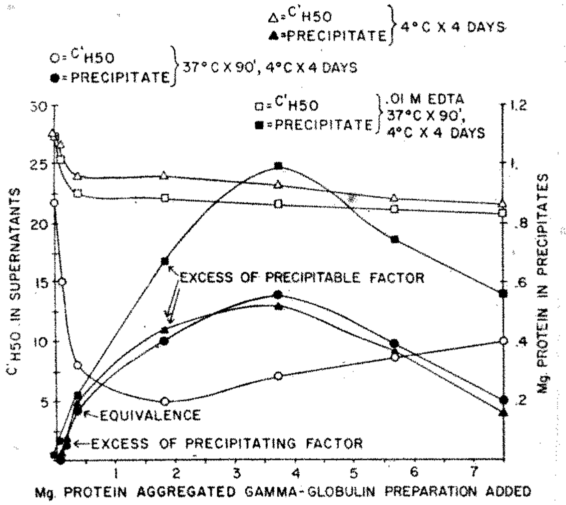

Fig. 1. Precipitating reaction between equal aliquots of normal human serum (1 ml.) and increasing amounts of aggregated γ-globulins: determination of precipitate protein, and of hæmolytic complement titre in the supernatants

Quantitative tests showed that the precipitation reaction could be inhibited by an excess of aggregated γ-globulins (Fig. 1). The supernatants were tested for presence of the precipitating serum factor (by mixing them with aggregated γ-globulins) and for the precipitable factor of aggregated γ-globulins (by mixing them with normal human serum). Three zones were thus found, one with excess precipitating factor, another with neither precipitating nor precipitable factor (equivalence), and a third with only precipitable factor in the supernatants. The amount of precipitate continued to increase beyond the equivalence zone, as is also observed in the precipitation reaction between rheumatoid serum and aggregated γ-globulins[5], as well as in classical antigen–antibody reactions, when the antigen is aggregated[6]. The amount of precipitate recovered from each tube usually failed to exceed the amount of aggregated γ-globulins added to the serum, which suggests that only a fraction of the preparation added takes part in the formation of the precipitate.

Decomplementation of the serum by absorption with 1·2 mgm. of heterologous antigen–antibody precipitates (bovine serum albumin–rabbit anti-bovine serum albumin, or egg albumin–rabbit anti-egg albumin) per ml. of serum prevented subsequent precipitation with aggregated γ-globulins.

Conversely (Fig. 1), the supernatants obtained after incubation for 90 min. at 37° C. and for 4 days at 4° C. showed a decrease in the titre of complement as measured in 50 per cent hæmolytic units. This 'anti-complementary' effect increased with increasing amounts of aggregated γ-globulins up to the area of maximal precipitation. It then, paradoxically, decreased, despite the addition of more 'anti-complementary' material, thus mirroring the decrease of precipitate. When the precipitating reaction was carried out completely at 4° C., the anti-complementary effect was much decreased (Fig. 1) and failed to mirror the amount of precipitate, which remained unchanged. This suggested a marked

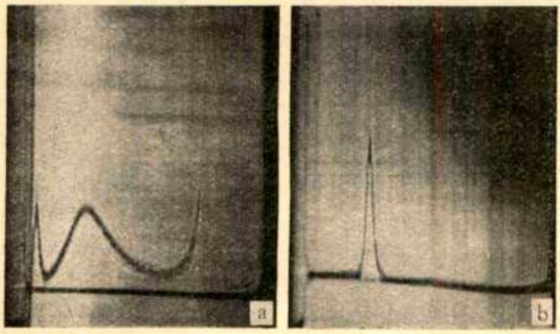

Fig. 2. Ultracentrifugal patterns of: (*a*) redissolved precipitate showing rapidly sedimenting aggregates and a small 10·5 *S* peak. Photograph taken during acceleration to 52,640 r.p.m. (*b*) purified 10·5-*S* precipitating component after removal of aggregates. Photograph taken after 32 min. at 52,640 r.p.m.

dependence on temperature for at least one step in the 'anti-complementary' effect of aggregated γ-globulins.

Fractional inactivation of components of complement[7] revealed that heat-inactivated serum (56° C. for 20 min.) deficient in the first and second components of complement, and the supernatant of serum dialysed against 0·02 molar phosphate buffer, *p*H 5·4 ('end-piece'), deficient in the first component of complement, failed to form a precipitate with aggregated γ-globulins. The redissolved precipitate ('mid-piece'), deficient in the second component of complement, formed a precipitate with aggregated γ-globulins, although 20–40 per cent less than untreated serum, and zymosan-inactivated serum, deficient in the third component of complement, and hydrazine-inactivated serum, deficient in the fourth component of complement, formed a precipitate with aggregated γ-globulins, with little or no loss of activity. These results suggested the possible identity of the precipitating factor for aggregated γ-globulins and the first component of complement. Since fixation of the latter is known to require calcium ions and to be inhibited by the chelating agent ethylenediamine tetraacetic acid[8], quantitative precipitation reactions were carried out with serum containing 0·01 *M* ethylenediamine tetraacetic acid (Fig. 1). The amount of precipitate was thereby increased, while the anti-complementary effect, measured in 50 per cent units after addition of a slight excess of calcium and magnesium ions to the supernatants, was much decreased, but not completely inhibited. These findings indicate that the precipitating factor, although suggestively similar to the first component of complement, is distinct from it as well as from the other hitherto known components of complement.

The precipitates were soluble in excess aggregated γ-globulins and in glycine buffer, *p*H 3. Ultracentrifugal examination of the acid solutions (Fig. 2) revealed a major component with an *s* rate of 9·5–10·5 *S*, large amounts of rapidly sedimenting aggregates, and frequently small 7 *S* and 19 *S* peaks. Following the removal of the aggregates by centrifugation, the major component had an $S^0_{20,\ 0\cdot15\ M\ \text{sodium chloride}}$ of 10·5 *S* and could again form a precipitate with aggregated γ-globulins. Similar findings have been reported independently recently by Müller-Eberhard and Kunkel[9].

This work was aided by a grant from the New York Chapter of the Arthritis and Rheumatism Foundation, by an advanced research fellowship of the American Heart Association (to A. T.), a rheumatic fever fellowship of New York State (to H. S. W.), and a senior research fellowship of the Arthritis and Rheumatism Foundation (to E. C. F.). BIOLOGY

Five Less-Common *Salmonella* Serotypes from Congo Reptiles

DURING work on dried specimens of cloacal contents collected in the Parc National de la Garamba, north-eastern Congo, from various reptiles, the following serotypes of *Salmonella* were isolated: *champaign* (39 : k : 1,5) from a snake; *Crotaphopeltis hotamboeia*; *plymouth* (46 : d : 1,6) from the same specimen of snake and from a lizard, *Mabuya* sp.; *ramat-gan* (30 : k : 1,5) from the same snake specimen; *tel-aviv* (28 : y : enz_{15}) from a different specimen of the same species of snake; and *gatow* (6,7 : y : 1,7) from a snake *Psammophis subtaeniatus sudanensis*. The identifications were made by the Enteric Laboratory, State of Illinois, Department of Health, and confirmed by the Enteric Laboratory, Communicable Disease Center, Chamblee, Georgia.

This is the second known report of the occurrence of serotype *ramat-gan*, the first isolations having been from snakes in Israel[1]. Likewise this is the second known occurrence of serotype *gatow*, which was first isolated from the sewage of Berlin-Gatow by Hofmann and is not yet formally published although confirmed by Kauffmann[2]. The *champaign* serotype, first described from chicks by Edwards in 1945, has been reported no more than ten times, from fowl, man, diarrhœa of infants, and a bird in a zoo, and from such widely separated places as the United States, Australia and Ceylon. Serotype *plymouth* has so far been published only in a list of new serotypes issued by Kauffmann[3]. There are only a half-dozen references to serotype *tel-aviv*, three of these being from Israel, where it was twice found in chicks and later once in man. It has been reported from West Germany, France and the United States. In addition to cultures from man and chick, this type has been isolated from dog fæces, bone meal and diarrhœa of children.

The specimens of cloacal contents were collected by soaking sterile disks of filter paper (Schleicher and Schüll No. 740-*E*) and enclosing each disk in a 'Cellophane' coin envelope. On arrival by air mail in Chicago, the disks were transferred to 10-ml. brain heart infusion, incubated at 30° C., and plated at intervals on deoxycholate agar in plates of 150 mm. diameter. From each plate about 30 well-isolated colonies were picked at random for identification. Of 587 strains classified biochemically, 267 were *Salmonella*.

In general, the biochemical reactions obtained were those typical of *Salmonella*. The few exceptions are noteworthy. All 15 cultures of serotype *champaign* were indole-positive although the other reactions were typical. All but a few of 83 cultures of *gatow* gave a weak but unmistakably positive indole test in 1 per cent tryptone broth cultures 48 hr. old, using the Kovacs test. A few *gatow* cultures were negative to lysis by *Salmonella* O-phage I[4]. A few of the many *plymouth* colonies tested gave positive tests for action on gelatin, and a few others were negative with O-phage I. Some *tel-aviv* cultures were also not lysed by that phage, but all the *champaign* cultures were sensitive, as were the cultures of *ramat-gan*. Several cultures of *tel-aviv* were salicin-positive and one was positive in both salicin and sucrose. During serotyping, it was observed that a number of strains of *plymouth*, *gatow* and *tel-aviv* were monophasic and required growth in homologous phase serum broth before the alternate phase could be demonstrated.

Most of the *Salmonella* types were represented by considerable collections. Picking 30 colonies from each plate produced duplicate isolations that would not occur by the usual method of picking single representative colonies of every kind seen. Further replication occurred because the same broth culture was plated several times after different incubation periods. With the single exception of the indole reaction of *champaign*, the majority of the strains of any serotype showed typical *Salmonella* characteristics. If only a single colony had been picked, then only the atypical reactions might have been observed and a conclusion drawn that reptilian *Salmonella* exhibited atypical characteristics. In describing new serotypes on the basis of single colonies, errors may thus creep into the description. It would seem advisable to follow the zoologists, particularly the entomologists, who emphasize the need to describe new species on the basis of suitable collections rather than single specimens, so that variations can be assessed.

The extent of distribution of *Salmonella* among reptiles is remarkable. In the present work *Salmonella* were recovered from two of three snakes of one species of *Crotaphopeltis*, one of *Psammophis*, and from a lizard, *Mabuya*. They were not recovered from single specimens of *Natriciteres* and *Philothamnus*. *Salmonella* have been isolated from snakes of the latter genus by LeMinor, Ravisse and Drean[5], who also found *Salmonella* in *Crotaphopeltis*. In their series of 575 snakes from Ethiopia, Eritrea and Lybia, Serie and LeMinor[6] found no *Salmonella* in snakes of the genus *Nahia*, but did find them in various snakes of the families Colubridae and Viperidae.

The investigation of which the present observations are a part is being made to explore the question: What is the bacterial flora of reptiles, and what is the significance of the presence of *Salmonella*? The extensive literature already shows that reptiles harbour *Salmonella*. Are these part of the natural intestinal flora of reptiles, or are they acquired through association with rodents, man or other sources? The herpetologist who collected the specimens and identified the reptiles felt certain that the chance of infection from man was negligible in the area of the Parc National de la Garamba, and that the specimens came from animals which would be extremely unlikely to feed on rodents. The present work is therefore believed to suggest that *Salmonella* are naturally present in the reptilian intestine, possibly as essentially harmless commensals.

For the opportunity to examine this material, grateful acknowledgment is made to the authorities of the Parc National de la Garamba (director, Dr. V. Van Straelen), Brussels, Belgium. The specimens were collected by Dr. R. F. Inger, curator of amphibians and reptiles, Chicago Natural History Museum, who also identified the reptiles. The work was supported in part by a grant (*E*-2437) from the National Institutes of Health, U.S.A.

Use of Polyethylene Glycol in Biology

IN a recent paper, I. Mackenzie Lamb[1] directed attention to the use of polyethylene glycol ('Carbowax') for the permanent preservation of algal material for microscopic study. He shows that it is practicable to preserve algae in the dry state embedded in polyethylene glycol and mounted on cards. When a portion is required for study, part of the card is snipped off and soaked in water. The alga then resumes its original state sufficiently well for detailed microscopic examination.

It seemed that such a technique could be expanded with advantage into a much wider field, and accordingly some simple experiments were carried out on plankton preserved in formalin in Aberdeen. Mixed phytoplankton, and individual copepods, decapod larvæ, chætognaths, medusæ and ctenophores were used. Phytoplankton from a preserved sample was added to a drop of 30 per cent polyethylene glycol on a slide and put aside to dry. The individual zooplankton organisms were similarly treated on slides, in a watch glass or evaporating dish according to size. Some were flooded with water the next day, others left for periods varying from a week to three months. Recovery takes only seconds on the slides, and a few minutes for the larger forms.

The phytoplankton samples were all in excellent condition and there was no difficulty at all in identifying the various species, including the delicate invertebrate larvæ, etc. The texture as seen with an oil immersion lens was surprisingly good. The chætognaths also recovered extremely well; the fin-rays, cellular structure of the corona and other features could be determined just as easily as in the originals, and there was no difficulty at all in dissecting out the teeth. Copepods and decapod larvæ also recovered well, perhaps somewhat shrivelled but not seriously so, and certainly well enough for easy dissection of the appendages. Medusæ and ctenophores did not recover their original size and shape and remained very shrivelled, but the texture of the tentacles of the medusæ and the combs of the ctenophores remained good and identification would be possible.

Such experiments are extremely crude and should be repeated in greater detail and with a wider range of species, but the method has such attractive possibilities that it is worth bringing it now to the notice of as many workers as possible.

A 30 per cent solution of polyethylene glycol is an excellent medium in which to examine and dissect specimens under a microscope. It penetrates quickly and clears the organism to what, in my opinion, is the ideal state for handling, leaving the fine setæ still visible. It is easy to lift the dissected parts through the surface film with a needle for further examination.

In addition to Lamb's technique for the dry storage of algae on cards, the following uses of polyethylene glycol are envisaged.

(1) Specimens of those types that recover well can be sent dry by post without special packing, and with a much-reduced risk of loss due to breakage of the jar or other container, and no risk of damage by leaking formalin to other goods in the post. Delicate or intricate specimens can be sent in a block of polyethylene glycol with no risk of displacement of parts.

(2) Micro-specimens can be sent dry, on a slide, to be recovered at the destination in such a form that they can be handled or examined by any desired technique.

(3) Parts of specimens dissected in a 30 per cent solution cannot come to harm by drying in transfer to the slide from a needle point, nor will they, or the specimen, be harmed if the observer has to leave his work to attend to something unexpected and of immediate priority. If this should result in his being unable to return to the work until after it has dried up, there is then no difficulty in resuming.

(4) Even carefully sealed museum tubes are liable to dry if not examined at regular intervals, and a minute crack, unseen at the time, can result in the complete loss of the specimen for most purposes. If preserved with polyethylene glycol added, there is a good chance that the loss would not be so serious, and a little more polyethylene glycol than the equivalent volume of the specimen simply added to the preservative should be a worth-while insurance.

It is also known as 'Carbowax' and is available in various melting points; Lamb suggests that that known as 'Carbowax 4000', melting point 55° C., is the most suitable. It is a white, rather waxy substance which dissolves readily in water, formalin and 70 per cent alcohol (but not in absolute alcohol). Specimens can be transferred to a solution at room temperature and allowed to dry if desired. For embedding in blocks, they can be transferred direct to the melted polyethylene glycol in a bath at 55° C. In Britain the cost is about 16*s.* per kgm., so that it is not expensive for so versatile and useful a commodity.

β-Glycosidase Activity and Cyanogenesis in the Susceptibility of Alfalfa to Winter Crown Rot

Hydrogen cyanide was demonstrated by Lebeau and Dickson[1,2] in alfalfa crown buds infected with an unidentified basidiomycete. They showed that a close association existed between the presence of hydrogen cyanide and mycelium in the infected buds, but did not determine whether the cyanide was produced by the fungus or host or was due to an interaction between the two. The experiments reported here were designed to clarify this problem.

Preliminary experiments were carried out to determine β-glycosidase activity of a crude enzyme preparation of the fungus cultured on a synthetic medium. Glycosidase activity of a crude enzyme preparation, obtained as the supernatant from centrifuged (13,000*g*) seven-day-old shake cultures, was determined by a modification of the Conway diffusion method[3]. 2 ml. of the crude enzyme and 1 ml. of a 0·02 *M* amygdalin solution were placed in the outer chamber and 1 ml. of alkaline sodium picrate[4] in the centre well of a Conway unit. Release of cyanide was indicated by a red coloration of the sodium picrate, which reached a maximum in 30 min. Activity of the crude enzyme preparation was not affected by dialysing but was destroyed by boiling.

Hydrogen cyanide has been reported from species of *Medicago*[5], and therefore a series of experiments was carried out to determine the effect of the crude enzyme on filtrates of *Medicago sativa* and *M. falcata*. Alfalfa crown buds obtained from plants under snow cover were homogenized for 30 min. in a Waring blender with sufficient distilled water added to facilitate homogenation. The homogenate was filtered through a double layer of cheese-cloth and the filtrate divided into two equal aliquots. Each aliquot was made up to 200 ml. with distilled water and transferred to a 500-ml. suction flask. Approximately 100 ml. of crude enzyme was added to the filtrate in one flask and an equal volume of distilled water to the other. Air was drawn through the reaction mixtures, passed through absorbent cotton and bubbled through 20 ml. of alkaline sodium picrate to indicate hydrogen cyanide production. Aeration was carried out at 15° C. for 48 hr. Control flasks containing distilled water or the crude enzyme were similarly treated. The optical densities of the picrate solutions were determined at 480 mμ using a Bausch and Lomb colorimeter. The results are shown in Fig. 1.

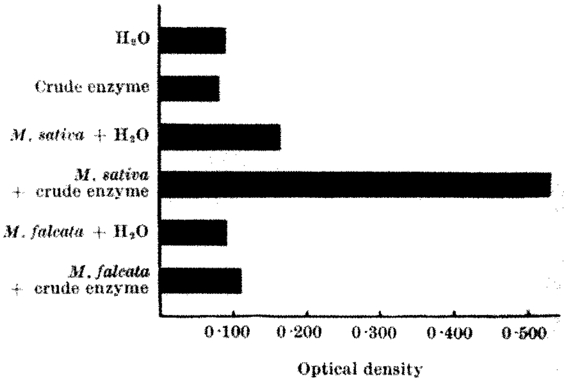

Fig. 1. Hydrogen cyanide production from filtrates of tissue homogenates of *Medicago sativa* and *M. falcata*

Hydrogen cyanide was released in an appreciable amount only from the *M. sativa* filtrate. Lack of activity with the *M. falcata* filtrate suggests that this material may have a lower glycoside content or, alternatively, contains a β-glycosidase inhibitor or a detoxification mechanism for cyanide. It appears likely therefore that production of hydrogen cyanide in infected alfalfa plants in the field is due to β-glycosidase activity on the part of the fungus and the provision of cyanogenic substrates by the host. The difference in response of the two filtrates is of particular interest since *M. falcata* is comparatively resistant to winter crown rot in the field.

Further work is being carried out, and detailed results will be reported in due course.

Ethylene Production by Cytoplasmic Particles from Apple and Tomato Fruits in the Presence of Thiomalic and Thioglycolic Acid

Despite several tracer studies[1,2] and the use of very sensitive techniques for the detection of ethylene[3,4], there has been no clear indication of a biosynthetic pathway that can evolve ethylene in fruits. Spencer[5] reported ethylene production by cytoplasmic particles from tomato fruit in the presence of malate and co-factors. This suggested that the biosynthesis of ethylene could be related to the metabolism of organic acids in the cells. Tracer experiments by Burg[2], however, showed no evidence linking ethylene evolution to Krebs cycle metabolism. Meigh *et al.*[4] could not detect ethylene in incubation mixtures containing apple mitochondria, malate and co-factors. The latter experiments are especially significant since they used apple mitochondria known to metabolize Krebs-cycle substrates, and the system for detecting ethylene was considerably more sensitive than that used in any of the other investigations. It therefore appears that ethylene synthesis in fruits must be associated with some other aspect of organic acid metabolism.

Recently we have isolated cytoplasmic particles, from apples and tomato fruits, that evolve ethylene in the presence of thiomalic and thioglycolic acid. Cysteine, glutathione, methionine, and other related compounds (thiodiglycolic acid, α-monothioglycerol, β-mercaptopropionic acid, carboxymethylmercaptosuccinic acid) did not replace the requirement for thiomalic or thioglycolic acid. Results of a number of experiments with particles from apples are summarized in Table 1. Similar results were obtained with particles from tomato fruit.

Table 1. Ethylene Production by Cytoplasmic Particles from Apples in the Presence of Thiomalic and Thioglycolic Acid

Flask content*			Ethylene† (µl./mgm. N/hr.)
Thiomalic	+ co-factors	+ no particles	0·0
Thioglycolic	+ ,,	+ no particles	0·0
Thiomalic	+ ,,	+ particles	0·019
Thioglycolic	+ ,,	+ particles	0·016
Thiomalic	+ ,,	+ denatured particles	0·0004
Thiomalic	+ ,,	− PO_4 + particles	0·004
Thiomalic	+ ,,	+ DIECA + particles	0·003
Thiomalic	+ ,,	+ DIECA + 10^{-5} *M* copper sulphate + particles	0·006

* The flask contents consisted of the following: 50 µm. thiomalic or thioglycolic acid, 3 µm. adenosine triphosphate, 60 µm. phosphate, 0·08 µm. coenzyme-*A*, and 400 µm. sucrose. 1 ml. of particulate suspension containing approximately 1·5 mgm. nitrogen was added to each flask. The flasks were incubated 2 hr. at 30° C. in an automatic shaker. The *p*H of the reaction mixture was 6·2.

† Ethylene was determined by gas chromatography with a system previously described (ref. 4). The method was sensitive to 3 × 10^{-6} µl. of ethylene in a 1-ml. sample.

These ethylene-producing systems have many characteristics of an enzymatic process. The rate of ethylene production is proportional to the concentration of the particles. The rate, during a 45-min. period, is approximately proportional to the length of the incubation, and the reaction is essentially inhibited by heat denaturation. The reaction appears to be stimulated considerably by phosphate. Furthermore, some chelating agents that inhibit enzymatic reactions, such as diethyldithiocarbamate (DIECA) and ethylenediamine tetraacetic acid (EDTA), markedly inhibited this reaction and the inhibition is partially reversed by the addition of copper to the system.

It is noteworthy that these preparations did not oxidize Krebs cycle substrates. Another important difference between mitochondria and these particles is in the *p*H of the isolating media. Whereas active mitochondrial particles are isolated from homogenates of neutral or slightly alkaline media, it was found necessary to isolate these particles from homogenates of acid media. Particles that cause the evolution of ethylene were obtained from fractions precipitated at 500*g*, 16,000*g* and 40,000*g*.

These findings offer a completely new approach to the study of ethylene biosynthesis. Work is now in progress on the purification of the enzyme or enzymes and the elucidation of the mechanism of the reaction by tracer techniques.

ENTOMOLOGY

Ribonucleic Acids in the Moult Cycle of an Insect

It is well known that the cuticle in insects is shed at the end of each instar and a new one is formed by the underlying epithelium. Although much is known about the histological changes in the epithelium and the chemical changes in the cuticle during this complicated process of moulting[1,2], nothing is known about the role of the ribonucleic acids (RNA) during this period. Since it is known that RNA plays an important part in cellular protein synthesis[3], it was considered desirable to study the RNA of the insects during the moult cycle.

In the present investigation the nymphs of *Gryllus bimaculatus* were used. Young nymphs, hatched within a period of 15 hr., were separated and maintained in the laboratory under identical conditions of temperature, light, humidity, etc., so that their rate of growth would be the same. Prior to the extraction of RNA, the nymphs were homogenized and treated successively with 2 per cent perchloric acid and an alcohol–ether mixture in order to remove the nucleotides and the lipids respectively. RNA was extracted by treating the residue, in the cold, with N perchloric acid for 18–24 hr. and estimated by the ultra-violet absorption and/or the orcinol method in the presence of ferric chloride. For purposes of comparison, total nucleic acids were extracted with warm 0·5 N perchloric acid and RNA was estimated by the orcinol reaction[4]. Histological preparations of nymphs fixed in Zenker's fluid have also been made and were stained with Unna's methyl green–pyronin stain.

The first-stage nymphs of *Gryllus bimaculatus* moult approximately at the end of the fifth day after hatching, while those of the second stage moult, usually, on the sixth or seventh day after the first moult. There is considerable individual variation in the time taken by the nymphs in the succeeding stages. Hence, for the quantitative estimations of the RNA, only individuals of the first two stages were used during this work.

Results are given in Table 1.

Table 1

Age of the nymph after hatching or moulting (days)	RNA content per mgm. weight of nymph (μgm.)	Total RNA per individual (μgm.)
1	7·2	5·6
2	5·1	4·6
3	4·5	8·1
4	0·7	1·3
5	0·7	1·3
Soon after first moult	0·8	1·6
1	2·1	6·3
2	2·4	7·5
3	5·4	21·2
4	7·6	32·0
5	2·4	11·0
6	0·7	3·3
Second moult		

It can be seen from Table 1 that the RNA content per mgm. wet weight of the nymph gradually falls from the time of hatching to the first moult, and then rises to a peak at the intermoult period; it decreases once again to a minimum at the time of the second moult. However, if we consider the total ribonucleic acid content per individual, it is evident that the RNA content reaches its highest figure, both in the first- as well as in the second-moult stage nymphs, at the middle intermoult period, that is, before the nymph is actually preparing for the succeeding moult. There is thus a gradual accumulation of RNA until the nymphs are preparing for the moult, and a sudden fall during the pre-moult period.

The histological preparations stained with Unna, after treatment with ribonuclease, or with buffer or without any pretreatment, showed a similar fluctuation in the ribonucleic acid content as indicated by the intensity of staining. The nucleoli in the chitogenous epithelium, which are prominent by their strong pyroninophily in the intermoult period (Fig. 1) are less visible in nymphs preparing to moult and in those which have just emerged from the moult (Fig. 2). Staining of the newly moulted (early post-moult stage) nymphs of the first five stages also showed faint staining of the nucleoli when compared with those of the intermoult stage nymphs. As the range of individual variation in the time taken for moult from the third stage onwards is great, day-to-day observations were no longer useful. However, such observations of the first two stages suggest that the nucleoli gradually become more prominent after the moult until the onset of the succeeding moult. On the contrary, the cytoplasm of the epithelial cells shows greater avidity for pyronine when the new cuticle is being laid, that is, just before and soon after the moult; while in the intermoult period, it is less pyroninophilic. In the adult insects of varying ages the epithelium shows only faint staining with pyronine both in the nucleoli and the cytoplasm.

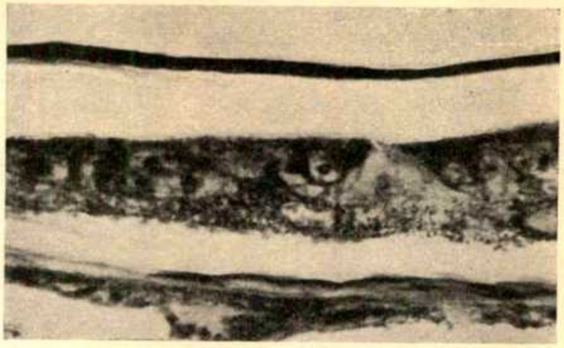

Fig. 1. Chitogenous epithelium of an intermoult second-stage nymph stained with Unna

The results reported above suggest that there is a gradual accumulation of RNA in the nymph from the time of moult until the late-intermoult period, and then a sudden decrease. Observations with methyl green–pyronin further show that the basophilia of the nucleolus and of the cytoplasm undergoes cyclic changes during the moult cycle, suggesting that nucleolar RNA might be transferred to the cytoplasm at the pre-moult stage. Finally, these observations indicate that the hormone which is secreted by the prothoracic glands and which is known to reach a titre sufficient to cause moulting some time before the processes involved in moulting are actually initiated[5,6] might influence the release of nucleolar RNA into the cytoplasm.

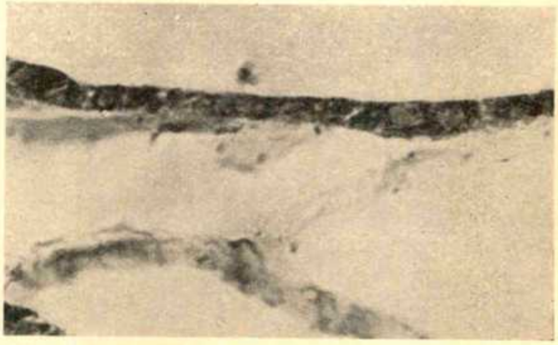

Fig. 2. Chitogenous epithelium of an early post-moult second-stage nymph stained with Unna

Trans-2-Hexenal in the Scent Gland of the Hemipteran *Acanthocephala femorata*

The plant bug, *Acanthocephala femorata* (Fab.), is one of the many hemipterous insects which eject odoriferous materials when disturbed. This large brown coreid, which occurs in the southern United States, is frequently found on citrus plants[1].

The scent gland secretion of *Acanthocephala* adults is stored in a large round reddish-orange sac which lies on the floor of the body cavity covering the metathoracic and first abdominal segments and extending to the second abdominal segment. This sac opens to the outside of the body-cavity through a pair of ostioles each of which is located on a suture between the sternal plate and the pleural plate of the metathorax. The ducts leading from the sac to the ostioles enlarge just inside each ostiole and can be opened to the outside by means of muscle-operated lips. The sac itself contains no obvious musculature for compression which would be required for ejection of the secretion. However, it was observed that ejection always occurred when the metathoracic legs were flexed. If the metathoracic legs were held immobile, no ejection occurred. Indeed, it was observed that movement of metathoracic coxæ from which the femora had been severed was coincident with ejection of the secretion. It is possible that the force required for ejection of the secretion is supplied by coxal pressure during contraction of the metathoracic leg; the secretion thus would be ejected when the lips of the sac ducts are simultaneously opened.

The secretion of *Acanthocephala* adults and nymphs issues as fine droplets. The adult secretion can be sprayed for a distance of at least 8 in. If one side of the body is mechanically stimulated, the spray is unilateral from the stimulated side. However, if the dorsum of *Acanthocephala* is stimulated, the spray is often bilateral.

Samples of clear yellow fluid from the sac were obtained by removing the abdominal dorsum and viscera of *Acanthocephala* and piercing the exposed sac with a fine capillary. Fluid collected in capillaries was identified as *trans*-2-hexenal by infra-red spectrophotometry, mass spectroscopy and the 2,4-dinitrophenylhydrazone derivative.

For infra-red spectrophotometry, a film of the secretion was used. The resulting spectrum demonstrated that the *Acanthocephala* secretion was a conjugated aliphatic aldehyde exhibiting *trans* deformation. The absorption bands were: aldehyde C—H, 3·66μ; C=O, 5·89μ; C=C, 6·08μ; *trans* C=C, 10·25μ. The spectrum was identical to that of 2-hexenal[2].

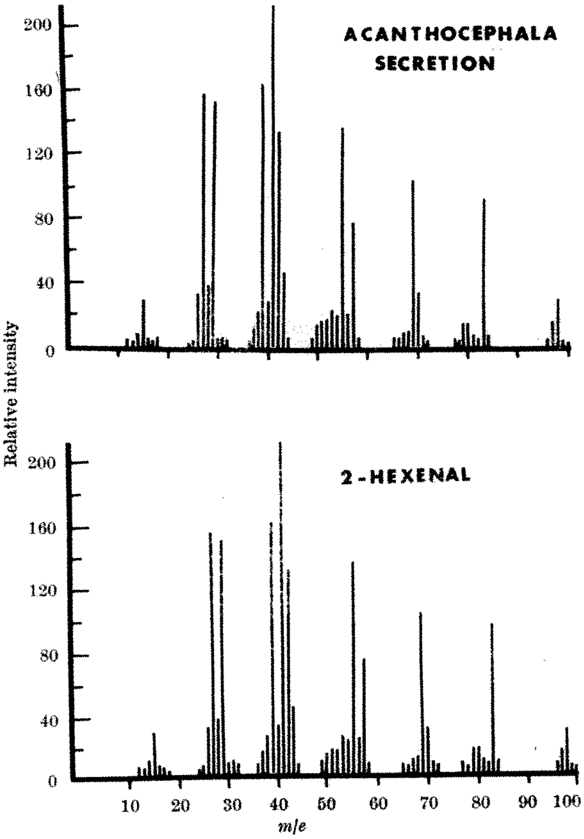

Fig. 1. Comparison of the mass spectra of 2-hexenal and the *Acanthocephala* secretion

The compound was analysed in a modified Consolidated 21–102 analytic mass spectrometer by injecting the compound with a microsyringe into the heated inlet system (100° C.) of the instrument. A normal magnet run at a pressure of 65·22μ indicated no masses above 98. A high magnet run further established the absence of any higher boiling components. Analysis of the structural fragmentation pattern established the *Acanthocephala* secretion as a hexenal which was identical with that of synthetic 2-hexenal (Fig. 1). Virtually superimposable fragmentation patterns indicated that the *Acanthocephala* secretion was a pure enal.

The 2,4-dinitrophenylhydrazone of the enal was prepared by adding an alcohol solution of the secretion to a saturated solution of the reagent in 2 *N* hydrochloric acid. The purified derivative melted at 144–145° C. uncorrected and did not produce a melting point depression in admixture with the derivative of synthetic 2-hexenal melting at 145–146° C.[3]. The elementary analysis of the *Acanthocephala* derivative corresponded to hexenal (found: C, 51·52; H, 5·15; N, 19·89; calculated for $C_{12}H_{14}N_4O_4$, C, 51·79; H, 5·04; N, 20·14 per cent).

2-Hexenal has also been found in the cockroach *Eurycotis floridana*[2]. In this insect the secretion is stored in a sac which opens to the outside of the body between the sixth and seventh abdominal sternites. It is of interest to note that males of the giant water bug *Lethocerus indicus* (Lepeletier and Serville) produce the acetate ester of 2-hexenal, which is given off through tubules located in the abdomen[4]. Elsewhere, 2-hexenal has been found in whale oil[5] and is a common constituent of plants[3].

Nothing is known of the function of 2-hexenal in Nature. It may serve as a repellent for predators of *Acanthocephala*. In the laboratory, *Acanthocephala* sometimes ejected this compound at imported fire-ants (*Solenopsis saevissima* var. *richteri* Forel) which were approaching. The ejection was unilateral to the side facing the ants and caused the ants to move away. When the ants actually attacked *Acanthocephala* it always ejected copious quantities of the secretion.

We are indebted to Dr. R. P. Curry of the Ethyl Corporation, Baton Rouge, Louisiana, for helpful discussion of the infra-red spectra and Prof. P. S. Callahan of Louisiana State University for morphological interpretations.

BACTERIOLOGY

Hæmolytic Activity of *Corynebacterium ovis*

THE Priesz–Nocard bacillus (*C. ovis*) which is responsible for a number of diseases of animals, including caseous lymphadenitis of sheep and ulcerative lymphangitis of horses, grows well on blood-agar medium, producing circular, opaque surface colonies which are frequently surrounded by a narrow zone of hæmolysis.

The hæmolysin, which is active against guinea pig, rabbit, horse and sheep corpuscles, is thermostable, non-antigenic and appears to be closely linked to the bacterial cells so that it cannot be obtained free in a filtrate[1].

During an investigation of the effects on animal erythrocytes of combinations of diffusible substances produced by bacteria (to be published), it was observed that mixed cultures of *C. ovis* and *C. equi* showed a synergistic hæmolytic effect on sheep, goat, ox and rabbit cells. The phenomenon was better illustrated by streaking the strains at right angles to each other on the surface of 1·5 per cent nutrient agar plates containing 4 per cent red cells which were previously washed three times in normal saline and re-suspended to the original volume of the blood. The inoculated plates were incubated in air-tight jars in a mixture of 10 per cent carbon dioxide and 90 per cent air, at 37° C. for 24–48 hr.

Fig. 1 shows the effect on sheep blood agar after 48-hr. incubation with the vertical culture streak of *C. ovis* running through the horizontal streak of *C. equi*. The hæmolytic pattern obtained is the result of the interaction of the diffusible products of both strains; that of *C. ovis* being active over a larger area than *C. equi* and neither exerting the hæmolytic effect independently. Unlike the hæmolysin described by Carne, the diffusible substance produced by *C. ovis* is active against ruminant and rabbit cells, but not horse red cells, and its effect is enhanced by the presence of 10 per cent carbon dioxide.

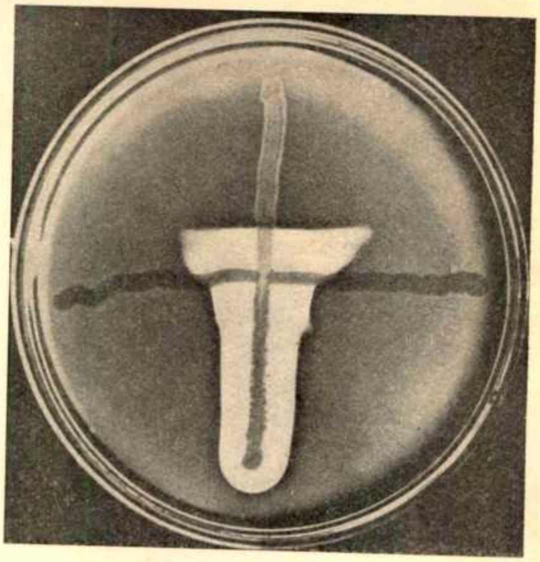

Fig. 1. Sheep blood-agar plate showing the hæmolytic effect of *C. ovis* in the presence of *C. equi*

The plate method, which appears to be more sensitive than tube titration, has also been used to show that the diffusible product of *C. ovis* is filtrable and is capable of dialysation through 'Cellophane'; and is being adapted for antigenic studies.

These preliminary observations suggest that an indicator system of animal erythrocytes previously treated with an actively growing culture of *C. equi* may prove of value in elucidating the true nature of the hæmolysins of *C. ovis*.

Inhibition of Multiplication of Bacteriophage by Actinomycin

IT has recently been found that actinomycin forms a complex with deoxyribonucleic acid but not with ribonucleic acid[1]. In this communication we wish to present evidence to show that the antibiotic prevents multiplication of the phage while permitting the growth of the host bacterium.

The actinomycin used in these experiments was crystalline actinomycin *S*[2,3], supplied by the Daiichi Seiyaku Pharmaceutical Co., Ltd. The standard methods used for handling bacteria and phage and for determining nucleic acid were those described in another communication[4].

Actinomycin *S* is known to prevent the growth of Gram-positive bacteria, but *Escherichia coli B*, a Gram-negative bacterium, used in this experiment, can grow actively in the presence of the antibiotic. Exposure of free *T2r* phage to 100 μgm./ml. of actinomycin *S* for 60 min. at 37° C. did not cause any activation of the phage. The effect of the antiiotic on phage reproduction was studied. Cells of . coli B, harvested during the logarithmic phase of rowth, were infected with $T2r$ phage and shaken at 7° C. in a glucose–salt synthetic medium with arious concentrations of actinomycin S.

The results are illustrated in Table 1, which shows hat the reproduction of $T2r$ phage is progressively npaired by increasing concentrations of actinomycin , while the synthesis of deoxyribonucleic acid in the hage-infected cells is not affected by the antibiotic. t must be emphasized that the infected bacteria roduce deoxyribonucleic acid in a similar way even when the antibiotic is added 5 min. either before or after infection.

able 1. EFFECT OF ACTINOMYCIN S ON THE MULTIPLICATION OF HAGE AND THE SYNTHESIS OF DEOXYRIBONUCLEIC ACID BY $T2r$-INFECTED BACTERIA

Concentration of actinomycin S (μgm./ml.)	Relative increase (percentage of control)	
	Phage titre	Amount of deoxyribonucleic acid
0	100	100
1	45	—
3	29	—
10	12	98
30	10	94
100	4	87

The lysate obtained in the presence of a level of 30 μgm./ml. of actinomycin S contained nearly the same amount of the deoxyribonucleic acid as that found in the untreated control lysate, but the infectivity of the former lysate was only one-tenth of the latter. When the lysates were centrifuged at 3,000g for 15 min., the majority of the deoxyribonucleic acid was found in the supernatant fluid, both in the presence and in the absence of the antibiotic. Hence analyses were made on these supernatant fluids. As shown in Table 2, a significant difference between the control and the antibiotic-treated lysates was revealed by comparing the amount of deoxyribonucleic acid in the sediment obtained by centrifugation at 20,000g. At this gravity, normal $T2r$ phage but not free nucleic acid was sedimentable. Furthermore, the deoxyribonucleic acid which had been produced by infected cells exposed to the antibiotic was not precipitable by anti-$T2r$ phage serum and was sensitive to deoxyribonuclease. These results indicate that this deoxyribonucleic acid has no protein coat reacting with the antiserum and protecting the viral deoxyribonucleic acid from deoxyribonuclease.

These effects of actinomycin S on phage reproduction are essentially similar to those of proflavine[5]. One may suppose that actinomycin S, like proflavine, blocks some final step in the maturation of the phage.

Table 2. PROPERTIES OF DEOXYRIBONUCLEIC ACID IN THE LYSATE MADE IN PRESENCE OF ACTINOMYCIN S

Fraction	Deoxyribonucleic acid found*	
	Control lysate	Lysate with actinomycin S
Initial lysate	100	100
Low-speed centrifugation supernatant	90	73
Sediment at 20,000g	34	2
Precipitate with antiserum	53	2
Deoxyribonuclease-resistant	39	10

* Values in each fraction represent percentage of the amount of deoxyribonucleic acid in the initial lysate.

However, there is a significant difference between the action of two inhibitors; the formation of infective phage is reversed by removal of proflavine, but not by removal of actinomycin S. Thus further work is necessary to determine whether normal viral protein is produced by the antibiotic-treated cells.

VIROLOGY

Effect of an Organic Gold Salt on Eaton's Primary Atypical Pneumonia Agent and Other Observations

Eaton, Liu and their colleagues have provided evidence that the causative agent of a certain type of human primary atypical pneumonia, namely, that in which a proportion of patients develop serum agglutinins against *Streptococcus MG* and human erythrocytes at 4° C., is filterable, can be propagated in the lung of the chick embryo, and produces lung lesions when inoculated into hamsters and cotton rats by the intranasal route[1]. Some uncertainty exists about the nature of this organism. The strains studied had a large particle size (between 180 and 250 mμ as measured by filtration[1b]); some were sensitive to streptomycin[2] and all to tetracyclines[3].

We have observed that the macroscopic and microscopic lesions produced in the hamster lung by the intranasal inoculation of chick embryo lung infected with the 'Hetter' strain of Eaton's primary atypical pneumonia agent resemble in some respects those seen in the lungs of mice infected intranasally with cultures of pleuropneumonia-like organisms[4].

The size of Eaton's organism is of a similar order to that given for the elementary particles of some pleuropneumonia strains (125–250 mμ), and its pattern of antibiotic sensitivity is also similar to that of the pleuropneumonia group[5]. Eaton and his colleagues were unable, however, to grow pleuropneumonia-like organisms from egg material containing strains of the organism[1].

It has been shown that organic gold salts will suppress lung[6] and other lesions[7] produced by pleuropneumonia-like organisms in animals, and accordingly we have investigated the effect of sodium aurothiomalate ('Myocrysin', May and Baker) on experimental infections with Eaton's primary atypical pneumonia agent in hamsters and chick embryos. The 'Hetter' strain of Eaton's agent, obtained from Dr. C. Liu and kindly given to us by Prof. C. H. Stuart-Harris (Sheffield), was used for all the experiments and was passed by the amniotic route in 13-day-old chick embryos. Infection was recognized in frozen sections of the lungs of the chick embryos by using the indirect fluorescent antibody method with a 'middle layer' consisting either of a pool of convalescent-phase sera from local patients with primary atypical pneumonia or, for checking, of a specific rabbit antiserum against the classical 'Mac' strain kindly provided by Dr. M. D. Eaton (Boston).

Groups of hamsters were inoculated intranasally with 0·6 ml. of a 10 per cent suspension of infected chick embryo lung. Some groups were given a daily dose of 3–5 mgm. of sodium aurothiomalate intraperitoneally. Others were kept as untreated controls or injected with the excipient without the gold salt. All groups were killed 11 or 12 days after intranasal inoculation and the intensity of their lung lesions graded on two arbitrary scales depending on (*a*) the macroscopic degree of lung consolidation, and (*b*) the proportion of bronchi and vessels with cuffs of mononuclear cells and the degree of alveolar consolidation seen in lung sections.

Table 1 shows the results obtained in experiments with four different egg passage-levels of the 'Hetter' strain. There was a consistent reduction in the intensity of the lung lesions in hamsters treated with gold. The lung lesions were also reduced to a similar degree (an average macroscopic lesion score of 0·12 was obtained as part of exp. 4) by a convalescent-phase serum from a local patient (Ev. S) with primary atypical pneumonia. This serum had a fluorescent antibody staining titre of 1 in 50 to 1 in 100 when titrated on infected chick embryo lung sections ; the patient's acute-phase serum did not stain at a dilution of 1 in 5. This neutralization provides an indirect check that the lesions produced in hamsters, and inhibited by the gold salt, were in fact caused by the 'Hetter' organism and not by a second (hypothetical) organism present in the egg material but unrelated to Eaton's agent.

Table 1. EFFECT OF SODIUM AUROTHIOMALATE ON THE LUNG LESIONS PRODUCED IN HAMSTERS BY EATON'S PRIMARY ATYPICAL PNEUMONIA AGENT

Exp. No.	Controls			Gold-treated		
	No. of animals	Average lesion score		No. of animals	Average lesion score	
		Macroscopic	Microscopic		Macroscopic	Microscopic
1	3	1·5	4·6	4	0·25	1·5
2	8	1·6	6·0	7	0·14	1·0
3	9	1·7	5·8	9	0·3	1·2
4	9	1·6	4·9	7	0·07	1·1

Analysis of the frequency distribution of the individual lesion scores for all fifty-six hamsters indicates that the differences between treated and untreated groups were unlikely to have arisen by chance alone. Macroscopic lesion scores : $\chi^2 = 31·5$; d.f. $= 5$; $P < 0·001$; microscopic lesion scores : $\chi^2 = 53·3$; d.f. $= 8$; $P < 0·001$.

In other experiments a single dose of 25 or 30 mgm. of sodium aurothiomalate was placed in the yolk sac of chick embryos either before, or at the same time as, the inoculation of a suitable dilution of the 'Hetter' seed into the amniotic cavity. Subsequent examination of frozen sections of the chick embryo lungs showed that substantially fewer of the treated groups had specific antigen ('fluor-stained antigen') when examined by the indirect fluorescent antibody method. Also pools of lung tissue from the treated embryos did not produce pneumonia in hamsters, whereas those from the control, untreated embryos did so.

These results are in accord with the view that Eaton's primary atypical pneumonia agent may be biologically related to the pleuropneumonia group. However, more information on the effect of gold on accepted viruses is required, although Bauer[8] found that neurovaccinia was not inhibited.

The results of intensified Giemsa-staining of sections of chick-embryo lung infected with the 'Hetter' strain also suggest an affinity between the agent and pleuropneumonia-like organisms. Acetone-fixed, frozen sections (about 5μ) were treated with 1 per cent potassium permanganate[9] for 2 min., washed and stained with 1 in 25 Giemsa in phosphate-buffer *p*H 6·4 for 18 hr. They were differentiated with 0·5 per cent acetic acid, washed and then either mounted in a mixture of equal parts of glycerol and phosphate-buffer and examined at once or—with more distortion and variability—dehydrated with acetone, cleared with xylol and mounted in a polystyrene (*DPX*).

Minute pink coccobacilliform bodies were seen in association with the bronchial epithelial cells. Some were intracellular, but the majority appeared to be arranged as a compact layer on the surface of the cells, and they seemed to occupy virtually the same position as the fluor-stained antigen found in adjacent or other sections of the chick-embryo lungs. (In our experience the exact location of the fluor-stained antigen is difficult to judge with the fluorescence microscope. The antigen might be completely within the cytoplasm of the bronchial epithelial cells and just under the cell membrane or, alternatively, it might be predominantly on the surface of the cells with some material taken into the cells by phagocytosis.) Coccobacilliform bodies have not yet been seen in sections of uninfected chick-embryo lungs. A close correlation has, however, been observed between the presence of fluor-stained antigen and coccobacilliform bodies in embryos inoculated with a variety of positive or negative materials. The coccobacilliform bodies appear at about the same time—three to four days after inoculation—as the fluor-stained antigen in injected chick-embryo lung, and, like the antigen, they are suppressed or reduced in quantity in embryos treated with sodium aurothiomalate. Further experiments are being carried out to obtain evidence from other directions on the identity, or otherwise, of the coccobacilliform bodies and the specific fluor-stained antigen.

As these findings may be peculiar to our sub-line of the 'Hetter' strain, it now seems desirable that other strains of Eaton's primary atypical pneumonia agent should be examined elsewhere for coccobacilliform bodies by the method of mild fixation and intensified Giemsa staining, and that they should also be tested for sensitivity to organic gold salts *in vivo*.

Hæmagglutination and Hæmagglutination-Inhibition with African Horse-Sickness Virus

Complement-fixation and mouse neutralization tests are the two techniques so far employed in serological work with African horse-sickness virus. It was thought worth while to study the hæmagglutinating properties of this agent with the view of obtaining yet another tool for epidemiological (epizootiological) studies of this dreaded horse disease.

The three strains studied were an Indian strain recently isolated from the lung of a dead horse, a Pakistan strain and an attenuated type 6 strain from South Africa. The latter two were kindly supplied by Dr. Alexander of the Onderstepoort Laboratory in South Africa. The Indian and the Pakistan strains had undergone approximately 20 and the type 6 strain probably 100 or more mouse brain passages.

The basic techniques for preparing antigens, sera and erythrocytes for hæmagglutination-inhibition test were those described by Clarke and Casals[1]. Antigens prepared from infected suckling mouse brains were : (1) acetone–ether extract ; (2) sucrose–acetone extract ; (3) sucrose–acetone extract treated with protamine sulphate ; (4) crude aqueous alkaline extract ; (5) the same treated with protamine sulphate. Control antigens were prepared from the brains of normal healthy mice of the same age. Erythrocytes collected from roosters, geese, sheep, guinea pigs, horse, mule and donkey were tested. The cell concentrations used ranged from 0·4 per cent to 1 per cent. The cells were suspended in 'adjusting diluents', which when mixed with an equal volume of 'serum–virus diluent' gave a *p*H range from 6·4 to 7·0. The hæmagglutination test was performed in tubes with 0·5 ml. of antigen and 0·5 ml. of required cell suspension. One set was incubated at 37° C., one at room temperature (25° C.) and one at 4° C.

Initial experiments revealed that this virus showed hæmagglutination with cells from the equines alone. As the most satisfactory pattern was obtained with horse cells, these were used for all further work. Only the two antigens (Nos. 3 and 5) treated with protamine sulphate showed hæmagglutination. Of the two, sucrose–acetone extract treated with protamine sulphate gave better results than crude extract treated with protamine sulphate. Control antigens prepared from normal mouse brains in the same manner did not show any hæmagglutination. The best results were obtained with 0·5 per cent horse red blood cells, using *p*H 6·4 and incubation at 37° C. The test was read within 1¾–2 hr., when the cell controls had settled. The three strains gave similar hæmagglutination titres ranging from 1 : 32 to 1 : 128.

Hæmagglutination-inhibition work is still in a preliminary stage. Removal of non-specific inhibitors from sera was attempted by treatment with kaolin, acetone extraction and inactivation at 56° C. for 30 min. Antigen and serial two-fold dilutions of serum were mixed in 0·25 ml. volumes and incubated either at 37° C. for 1 hr. or overnight at 4° C. After incubation, 0·5 ml. of cells was added. Of the three methods of treating sera, acetone extraction appeared to be the best. From the limited trials it seemed that kaolin might reduce the level of specific antibodies. Overnight incubation at 4° C. produced better results than those observed with incubation at 37° C. for 1 hr.

Table 1

Serum No.	CF titres (reciprocal of initial serum diluted with 4 units of antigen Indian strain)	Log neutralization index*	HI titres (reciprocal of initial serum diluted with 4 units of antigen Indian strain)
603360–3	32	3·1 to $\geqq$ 3·5	40–160
603366–5	8	3·0 to $\geqq$ 3·1	20–80
603381–4	32	2·5 to $\geqq$ 3·7	160–640
603390–3	16	$\geqq$ 3·5	80–320
603661–2	8	2·2 to $\geqq$ 4·0	20–80
603665–2	32	2·7 to $\geqq$ 4·0	40–160

* Adult mouse IC test with several Indian strains, using constant serum-varying virus dilutions.

CF, Complement-fixation ; HI, hæmagglutination-inhibition.

A group of horse sera collected during a recent epidemic in India were tested for hæmagglutination-inhibition. Six sera that did not show detectable complement-fixing and neutralizing antibodies were also negative for hæmagglutination-inhibiting antibodies. Table 1 compares the complement-fixation, neutralization and hæmagglutination-inhibition results of the remaining six sera. The hæmagglutination-inhibition pattern, while clearly indicating inhibition, is not yet entirely satisfactory. The end-point is not as sharply defined as in tests with other viruses but is spread over several tubes. For this reason the hæmagglutination-inhibition titres have been presented as ranging over several tubes.

McIntosh[2] has reported that the complement-fixation test is less type-specific than the neutralization test and that no antigenic differentiation between the heterotypic strains was possible. Work is in progress to determine if the hæmagglutination-inhibition test is type-specific.

I wish to thank Drs. Tara B. Gokhale and Keerti V. Shah for carrying out the complement-fixation and neutralization tests.

GENETICS

Developmental Barriers in a Selection Experiment

The present experiments describe the effect of selection on expression of the *ocelli-less* mutant, sex-linked recessive, affecting the ocelli and three pairs of macrochætes on top of the head in *Drosophila subobscura*.

In the foundation population, homozygous for the *ocelli-less* mutant, a large number of flies lacked all 3 ocelli and all 6 bristles ; in the rest, varying combinations of bristles and ocelli were present. The ocelli in some of the flies were found to be slightly displaced from their normal positions, and in certain cases their sizes were also affected. In a few flies the bristles were found to be repeated ; instead of one normal bristle on one side, additional bristles were found to lie close to the normal bristle. A positive correlation ($r = 0·46$) was found between the presence of bristles and of ocelli. Therefore, in measuring the degree of expression, a unit score was given for the presence of each of the 6 bristles and 3 ocelli. Thus a fly completely lacking ocelli and bristles would have a total score of zero and a wild-type fly a total score of 9. No addition to the total score was made for repeated bristles; but their frequency was recorded in the foundation population and in the last few selected generations. The word 'score' will be used throughout in the sense here defined.

In the foundation population the mean score of females was 1·76 and of males 1·44; the sex difference, although small, was found consistently in all the cultures scored.

Directional selection was effective in increasing the mean number of ocelli and bristles almost to the wild-type score of 9 in the upward direction, and decreasing the score to zero in the downward direction. Both the variance of the score and the sex difference in score were greatest in populations the mean score of which was at the centre of the range.

The distribution of the phenotypes in the selected populations suggested that there exists a developmental barrier which prevents progress beyond the upper and lower bounds. These bounds were sharper in the downward direction because other bristles were rarely affected by the mutant. The flies, however, after reaching the score of zero, showed a notch-like depression on the lower margin of the head, which varied in the degree of expression. In the upward selected population, in the last generations of selection, a few flies with extra ocelli were seen, and the frequency of repeated bristles was found to be considerably greater than that in the foundation population.

In Fig. 1 a genetic model is shown to explain the bounded distribution of phenotypes, in terms of genes which in their primary effects on an ocelli-bristle-forming substance are additive throughout the range.

In Fig. 1*a* it is supposed that there are a number of pairs of alleles which alter the expression of the *ocelli-less* flies by altering the amount of some 'precursor' which is necessary for the formation of ocelli and bristles, and which is normally present in the required amount in wild-type flies having the + oc gene. In *ocelli-less* flies the amount of this precursor is variable, but usually less than in flies carrying the +oc gene. Now if the amount of the precursor is less than T_1, no ocelli or bristles are formed. If it is between T_2 and T_3 the wild-type score of 9 is produced. Flies having amounts of precursor intermediate between T_1 and T_2 tend to produce intermediate scores. Only flies having the amount of precursor greater than T_3 produce a score greater than 9. That flies with an amount of precursor within the range T_2–T_3 should all have the same phenotype of 9 is to be expected from Waddington's argument concerning canalization[5]. The amount of precursor in flies carrying the +oc gene is unlikely to be absolutely constant. If we suppose, as shown in the diagram, that +oc flies have an amount of precursor within the range T_2–T_3, then canalizing selection during the past evolution of the species would ensure that the same adult phenotype would develop provided that the amount of precursor is within this range.

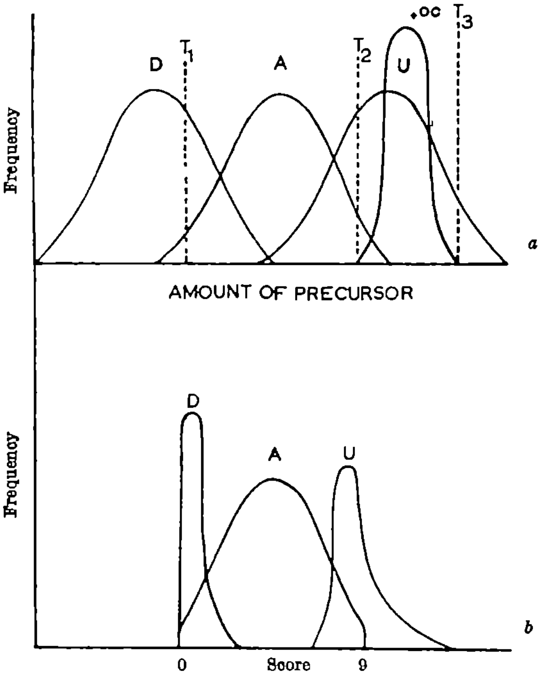

Fig. 1. Model to explain the bounded distribution of phenotypes

The three populations *A*, *D* and *U* in Fig. 1*b* represent, respectively, the phenotypes of a population with a mean score at the centre of the range and downward and upward selected populations. In *A* the genetic variance of the score is largely additive, but in populations *D* and *U* the genetic variance of the score is largely epistatic.

The concept of the 'amount of precursor' has been introduced to facilitate the discussion. A similar model could be given if it were assumed that the different scores are determined by differences in the competence of cells to respond to an unvarying pre-pattern[4].

On the basis of this model most of the experimental results can be explained satisfactorily. A similar model has been suggested by Rendel to explain the results of selection on the scute phenotype in *Drosophila*[2]. However, the situation is complicated by the fact that in some of the flies repeated bristles or bristles at new sites were seen, even in the absence of other bristles or ocelli, suggesting that the flies are abnormal not only in the amount of the precursor but also in its distribution. The main aim of the model, however, is to show how a bounded distribution of adult phenotypes with epistatic genetic variance could be the result of a character, which, if measured earlier in development, is continuously varying and of which the genetic variance is additive.

A more detailed account of this work is given elsewhere[3]. The genetic mechanisms responsible for the distribution of the ocelli-bristle-forming precursor have been described by Maynard Smith and Sondhi[1]. By selecting flies for the symmetrical and asymmetrical patterns of ocelli it has been shown that selection can alter not only the amount of precursor but also its distribution along the antero-posterior gradient, although it cannot modify its distribution along a gradient from left to right.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Prof. W. R. Hawthorne: "The Early Development of the 'Dracone' Flexible Barge" (Thomas Lowe Gray Lecture).

Society of Chemical Industry (joint meeting of the Food Group and Oils and Fats Group, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Prof. A. C. Frazer: "Some Biological Effects of Heated Fats".

British Institution of Radio Engineers, Electro-Acoustics Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. K. R. McLachlan: "Noise Correlation Measurements".

Society for Analytical Chemistry, Microchemistry Group (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "Hydrogenation Methods in Microanalysis" opened by Mr. R. A. D. Smith.

Royal Institute of Chemistry, London Section (joint meeting with the Slough College Scientific Society, at the Slough College of Further Education, William Street, Slough), at 7.30 p.m.—Prof. R. S. Nyholm, F.R.S.: "Magnetism in Inorganic Chemistry".

British Psychological Society, Medical Section (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 8.15 p.m.—Annual General Meeting, followed by Mr. S. H. Foulkes: "Psychotherapy 1961" (Chairman's Address).

Thursday, January 26

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. D. Bloor, Mr. T. J. Dean, Mr. G. O. Jones, Mr. D. H. Martin, Mr. P. A. Mawer and Mr. C. H. Perry. "Spectroscopy at Extreme Infra-Red Wave-lengths"; Mr. G. O. Jones, Mr. D. H. Martin, Mr. P. A. Mawer and Mr. C. H. Perry: "The Lattice Resonances of Ionic Crystals".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. E. S. Maurer. "Flowers and Perfumes": Dr. S. M. Manton, F.R.S.. "Evolutionary Paths to Success Among the Millipedes".

University of London (at Westfield College, Kidderpore Avenue, Hampstead, London, N.W.3), at 5.15 p.m.—Prof. E. H. Sondheimer "The Mathematical Description of Nature"* (Inaugural Lecture).

University of London (in the Bearsted Theatre, London Hospital Medical College, Turner Street, London, E.1), at 5.30 p.m.—Dr. F. C. Fraser: "Adaptations in Cetaceans".*

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. W. V. Mayneord: "Radioactivity of the Human Environment".* (Fifth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

University of London (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. T. Vályi-Nagy (Debrecen, Hungary): "Pharmacology of Antibiotics".*

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Informal Discussion on "Applications of Electronic Computers in the Study of Applied Mechanics and Electronic Computing in Engineering Design".

Friday, January 27

Institution of Mining Engineers (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 11.15 a.m.—67th Annual General Meeting. Mr. R. A. Moore: Presidential Address.

Institute of Rural Life at Home and Overseas (at Friends International Centre, 32 Tavistock Square, London, W.C.1), at 1.15 p.m.—Dr. Wallace Aykroyd: "The Work and Objectives of F.A.O.".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. P. B. Medawar, F.R.S.: "Principle and Paradox in Eugenics" (The Woodhull Lecture).

Saturday, January 28

Biochemical Society (in the Courtauld Hall, Queen Elizabeth College, Campden Hill Road, London, W.8), at 10.25 a.m.—402nd Meeting.

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss F. Hall: "Animal Courtship".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant, Grade B (with a good honours degree in physics) in the Department of Physics and Mathematics—The Principal, College of Further Education, Flatt Walks, Whitehaven, Cumberland (January 27).

Assistant (with some knowledge of fresh-water biology and chemistry) in the Fisheries and Pollution Department, for duties which will include the inspection of sewage works and trade waste treatment plants, river surveys, and the examination of samples.—The Chief Engineer, Somerset River Board, The Watergate, West Quay, Bridgwater, Somerset (January 30).

Assistant Lecturer in Physics—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (January 31).

Assistant Lecturer or Lecturer in Organic Chemistry—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (January 31).

Examiner (with a first- or second-class honours degree (or equivalent) in chemistry and two years experience in chemistry) of Applications for Patents—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, Republic of Ireland (January 31).

LECTURER (medical graduate, with experience in virology and in research methods) IN BACTERIOLOGY—The Secretary, The University, Edinburgh (January 31).

LECTURER or ASSISTANT LECTURER IN INORGANIC CHEMISTRY—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (February 3).

RESEARCH WORKER (graduate, familiar with numerical methods and computers), to study calculations performed in the shipbuilding industry and to construct programmes for an automatic computer—The Director, University Computing Laboratory, 1 Kensington Terrace, Newcastle upon Tyne 2 (February 4).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN BIOCHEMISTRY, CHEMISTRY, CIVIL ENGINEERING or PHYSICS—The Registrar, Trinity College, Dublin, Ireland (February 12).

PROFESSOR OF MATHEMATICS (EITHER PURE OR APPLIED)—The Registrar, The University, Leeds 2 (February 14).

READER IN EXPERIMENTAL PATHOLOGY at the Institute of Cancer Research, Royal Cancer Hospital—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 16).

HEAD (with good academic qualifications, with teaching and/or industrial experience) OF THE DEPARTMENT OF APPLIED CHEMISTRY—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (February 17).

LECTURER (with at least a good honours degree in geography, and preferably with experience of teaching geography in a university department) IN GEOGRAPHY at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth 36 Gordon Square, London, W.C.1 (Hong Kong and London, February 17).

RESEARCH FELLOW IN THE DEPARTMENT OF PHYSIOLOGY, John Curtin School of Medical Research, Australian National University, to work in the field of neurophysiology—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, February 17).

READER IN MICROBIOLOGY at Queen Elizabeth College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 21).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOW IN BIOCHEMISTRY, CHEMISTRY, ENGINEERING, PHARMACOLOGY or PHYSICS or related subjects—The Secretary, The University, Aberdeen (February 25).

ASSISTANT LECTURER (honours graduate) IN PHYSICS; and ASSISTANT LECTURERS (2) (honours graduates) IN BOTANY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (February 28).

ASSISTANTS (2) ONE IN MATHEMATICS and ONE IN STATISTICS—The Secretary of University Court, The University, Glasgow (February 28).

RESEARCH FELLOW IN MATHEMATICS—The Secretary of University Court, The University, Glasgow (February 28).

SENIOR LECTURER (with high mathematical qualifications and preferably previous experience in working with a digital computer) IN MATHEMATICS at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, February 28).

LECTURER IN PHILOSOPHY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, March 4).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY or PHYSICS—The Registrar, The University, Hull (March 7).

LECTURERS (2) IN ENGINEERING MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (March 10).

LECTURER (with an honours degree in metallurgy or a related subject, or with equivalent qualifications) IN CHEMICAL AND PROCESS METALLURGY at the Wollongong Division (University of New South Wales)—The Agent-General for New South Wales, 56 Strand, London, W.C.1, and the Appointments Section, University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (March 30).

ASSISTANT DIRECTOR (with a good science degree, preferably with some knowledge of genetics and/or statistics, and a knowledge of at least two foreign languages) OF THE BUREAU OF ANIMAL BREEDING AND GENETICS, King's Buildings, West Mains Road, Edinburgh 9—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (March 31).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN BIOCHEMISTRY, CHEMISTRY, CHEMOTHERAPY, ENGINEERING, METALLURGY, PHARMACOLOGY or PHYSICS—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 15).

ASSISTANT BIOCHEMIST (with a first- or second-class honours degree in chemistry or biochemistry) IN THE AREA PATHOLOGY LABORATORY based at Stoke Mandeville Hospital—The Administrative Officer, Stoke Mandeville Hospital, Aylesbury.

ASSISTANT EXPERIMENTAL OFFICER (with a pass degree in zoology or bacteriology and preferably experience in serology), for work in the Serology Section—The Secretary, Research Institute, Pirbright, Surrey.

ASSISTANT or ASSOCIATE PROFESSOR (with an honours degree in mathematics and preferably some postgraduate experience in research or teaching) IN THE DEPARTMENT OF MATHEMATICS—Head, Department of Mathematics, University of New Brunswick, Fredericton, N.B., Canada.

CHAIR OF PHARMACY—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C.1.

CHEMIST (with a first- or second-class honours degree in chemistry or equivalent qualification, and preferably experience in the inorganic analytical field and a knowledge of geochemical techniques) in Nyasaland, to take charge of the Geological Survey Department's chemical laboratory and to undertake assaying and chemical testing of rocks, including full silicate rock analyses—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/4/04.

EXPERIMENTAL OFFICERS (2) (graduates in physics or chemistry and interested in research in the field of high temperature gas dynamics), for plasma jet research—Head of the Aeronautics Department, Imperial College of Science and Technology, London, S.W.7.

PHARMACOLOGIST, BIOCHEMIST or ORGANIC CHEMIST with biologica experience (Ph.D. standard), for work in the field of chemotherapy—The Secretary, Medical Research Council of Ireland, 50 Merrio Square, Dublin, Republic of Ireland.

RESEARCH ASSISTANT (preferably graduate, with laboratory experience in chemistry or biochemistry), for work on amino-acid metabolism—Dr. L. I. Woolf, Department of Regius Professor of Medicine Radcliffe Infirmary, Oxford.

SENIOR SCIENTIFIC OFFICER (with a good honours degree in on of the following: agriculture, chemistry or biochemistry, with a least two years research experience), to act as Secretary of a propose Research and Development Committee which will be concerned with problems relating to the growing, harvesting, handling and marketing of potatoes—Establishment Officer, Potato Marketing Board 50 Hans Crescent, Knightsbridge, London, S.W.1.

EMPLOYMENT OF WOMEN SCIENTISTS AND ENGINEERS

THE report of an inquiry conducted by the Social Survey of the Central Office of Information into the employment of qualified women scientists and engineers in private manufacturing industry shows clearly that, in general, industry in Britain is a man-dominated world and is likely to remain so for many years to come*.

The sample of establishments covered by the survey was weighted in favour of industries which employ a high proportion of qualified scientists and engineers, and was drawn from establishments with two hundred workers or more which in 1956 were known to employ scientists and engineers. The number of establishments which took part in the survey was 785, employing between them 16,350 qualified scientists and engineers, that is, about 25 per cent of all those engaged in manufacturing industry.

Of the co-operating establishments, only about 98 (13 per cent) employed women scientists and engineers at the time of the survey. A further 85 (11 per cent) establishments had employed women scientists and engineers in the past but did not do so at the time of the inquiry. The 785 co-operating establishments employed between them 15,972 male and 378 female qualified scientists and engineers ; that is, 42 qualified men for every qualified woman. Only eight of the 378 women were engineers. On the assumption that the ratio of scientists to engineers in the sample was the same as in manufacturing industry as a whole, the ratio of male to female scientists was fifteen to one, and of male to female engineers more than a thousand to one.

An interesting feature of the inquiry was the views put forward by managers indicating their reasons for not being enthusiastic about the employment of qualified women scientists and engineers. Three main disadvantages were repeatedly mentioned, namely, that women were too likely to leave because of domestic commitments, including marriage ; that there were difficulties about having them in authority over, or working with, male personnel ; and that rough, dirty and physically hard working conditions were unsuitable for women.

Despite all the pleadings put forward by women's organizations, these are cogent points to support views strongly held by cost-conscious industrial managements. The training of scientific and technical personnel for responsible positions is an expensive process, and the facilities are much more readily given to those who are likely to stay with firms than those who are likely to go.

Qualified women are unlikely to become acceptable in industry until the shortage of technical personnel has become so acute that employers are prepared to accept them although fully aware of the fact that they are much more likely to have left within a few years than members of the opposite sex. Not all the views expressed by management, however, can be substantiated. Far too much is made of the case that male staffs object to having women in authority over them. In the Social Survey inquiry, for example, there was considerable difference between the views of those managements which had employed women scientists and those which had never employed them. Where there was experience of employing women scientists, it was much more often held that the male staff were in favour of their employment or had no objection to it.

Not unexpectedly, there is far greater objection to the employment of women engineers than women scientists. The conditions under which professional engineers often have to work, for example, dealing with heavy and dirty machinery, plant and site work, and shift work, are regarded as unsuitable for women while the control of male labour in engineering organizations would be possible only for the most exceptional women engineers. It is significant that very few employers in the survey had had any actual experience of employing women engineers.

In many ways the second part of the survey is likely to be of greater use in enabling educated women to find a suitable niche in industry. It was concerned with the actual experience of women who had taken university degrees in science or engineering in recent years. The sample taken was one in two of all women scientists who had graduated in 1954 and 1956. These years were chosen because women who graduated in 1954 could still be traced and would have had at least four years in which to gain experience of employment in industry and elsewhere. Those who had graduated in 1956 would have had only a little more than two years employment: but it was felt to be worth while to find out whether the situation had changed in recent years.

Of the 708 women in the sample, 381 were unmarried, 214 were married without children and 133 were married with children. The number working full-time was 513 (73 per cent), of whom all but 7 were single or married without children. Thirty-five were working part-time and 160 (22½ per cent) were not in paid employment. All except 31 (4 per cent) had had a paid job since graduation. Of the single women in the sample, 92 per cent were working full-time, and, of the married women without children, 73 per cent were working full-time.

Of the graduates who were still working full-time at the time of the survey (513), about half of them were, or had been, employed in teaching. The next largest proportions were engaged in research and development, and testing, analysis and product control, which bears out the finding in the employers' survey that these were the jobs in industry in which women scientists were most often engaged. 74 per cent of the graduates were employed in professional services, only 19 per cent in the industries included in the employers' survey, and 7 per cent were in other businesses. The professional services include education, medical and hospital services, and trade and professional associations; other businesses include gas, electricity and water, transport, national and local government, insurance, banking and finance, and catering.

---

* *Ministry of Labour Gazette*, September 1960.

In general, graduates working in private manufacturing industry were earning more than those in the professional services and in other businesses. Thus, of the graduates in private industry, 39 per cent were earning £800 or more per annum compared with 23 per cent in the professional services, and 30 per cent in other businesses. Because of the high proportion of graduates employed in teaching, the level of salaries shown as paid in the professional services must have been greatly influenced by the lower salaries in the teaching profession.

Women science graduates were asked whether their jobs offered prospects of promotion and whether, in their view, male colleagues were given preferential treatment. Of those employed in manufacturing industry more than half (52 per cent) thought that there was no prospect of promotion, and rather less than half (42 per cent) believed that there was. In the professional services, which included teaching, these proportions were reversed. In the 'other businesses' category a much higher proportion of women (69 per cent) thought that there were prospects of a better job.

More than half the women scientists employed in private manufacturing industries thought that their employers showed bias in favour of men as regards pay and promotion, but only 16 per cent in the professional services thought so. There were many in the latter group, however, to whom the question did not apply because all their colleagues, for example, in girls' schools, were women.

From both parts of the survey one conclusion is inescapable. Employers are reluctant to employ educated women scientists and engineers mainly because, on economic grounds, they are a bad risk; the present preponderance of eligible males over females in the population means that less and less females are avoiding marriage. Changing social behaviour has also led to a marked reduction in the age at which marriage is contracted; and, although the majority of newly married women are staying at work for some time after marriage, the age at which they bear their first child is also being reduced. From the employer's point of view, their years of useful service before beginning full-time duties in their homes is very limited. All the well-meaning protestations by women's organizations will not make young women scientists and engineers anything but a bad industrial investment compared with their male counterparts. Most educated women know this and accept it.

Although this view may not be openly expressed by employers, or may be hidden by plausible excuses about women's inability to control male staffs or put up with bad working conditions, its force is so strong that there are to-day more vacancies for women scientists in industry than there are women available to fill them. In spite of the greater financial attractions of industry, qualified women turn to careers where they feel wanted, where there are greater opportunities for positions of responsibility and promotion, and, above all, where they are likely to be acceptable again in their early forties when their child-bearing and home-making functions may have finished. For this reason, and because of the difficulty of keeping up to date in science and technologies which demand continuous reading, discussion and practice, women are still looking for careers in teaching, medicine, catering, personnel management and those branches of the professional and social services where the 15–20 years spent in raising a family may prove not a handicap but an asset. It is to be hoped that, on their return to employment, responsible authorities will recognize the added maturity and experience which marriage has brought and, after an appropriate settling-down period, see that they are not debarred from opportunities of promotion.

PAUL EHRLICH'S COLLECTED PAPERS

The Collected Papers of Paul Ehrlich

Compiled and edited by Dr. F. Himmelweit, with the assistance of the late Martha Marquardt. Under the editorial direction of Sir Henry Dale. Vol. 2: Immunology and Cancer Research. Pp. viii+562+9 plates. Vol. 3: Chemotherapy. Pp. viii+615+6 plates. (London and New York: Pergamon Press, 1960.) 160*s*. net each.

WITH these two volumes practically all the publications of Ehrlich alone or jointly are concluded. Volume 2 contains research on immunity. This work really started with the immunization of animals against plant toxins (ricin, etc.) and showed that, in analogy with Behring and Kitasato's diphtheria antitoxin, a specific antiricin appeared in the blood serum. Further, the important discovery was made that its action could be demonstrated *in vitro* as well as *in vivo*. Experience so gained was then applied to the practical problem of assessing quantitatively the antitoxin content of antidiphtheria sera. Besides finding a solution, Ehrlich also formulated the famous side-chain or receptor theory to explain the mechanism of antibody formation in general. This embodied a conception already presented in his "Sauerstoff Bedurfniss". The work was entitled "Die Wertbemessung des Diphtherieheilserums" (a translation is supplied). Further studies on immunity, especially with Bordet's hæmolysins, led to a series of papers, which were re-issued together as "Gesammelte Arbeiten zur Immunitätsforschung". In the preface Ehrlich states that the volume shows how his theory of immunity is "essentially the summary of an extraordinarily large number of exact investigations". However, nearly two-thirds of the papers does not bear

Ehrlich's name and so is omitted here, as is the case also in other sections. This must be understood, otherwise readers might infer that *The Collected Papers* contains all the work of the school inspired and directed by Ehrlich. Doubtless the matter exercised the editors; further inclusions certainly would have weighted the enterprise heavily. Of course, he usually quoted his co-workers' results, since they contributed to support Ehrlich's theories, which were indeed "all his very own". But occasionally some finding was documented which had no significance in this context, although afterwards found to be important in quite another connexion. The side-chain theory, in so far as it identifies antibody formation with normal processes of cellular metabolism, has not been superseded. But various features have required revision, for example, the amboceptor hypothesis. Also, the production of auto-antibodies and their pathogenic effects are now recognized as occurring widely, while factors which may antagonize antigenicity (immune tolerance) or influence allergy are gaining prominence. The experimental work on cancer by Ehrlich and Apolant, also in Volume 2 (but only a part of the Institute's publications in this field), was invaluable in establishing this line of research. But Ehrlich's nutritional theory of athrepsy to account for certain phenomena of tumour-growth has not yet produced striking developments.

Volume 3 comprises the chemotherapy of infections. The original essay (1891) was the successful treatment with methylene blue of two cases of indigenous quartan malaria, this dye being suggested apparently by its strong affinity for the malarial amœba. But thirteen years passed before systematic investigation on chemotherapy in experimental trypanosomiasis began—that with Shiga, on trypan-red. In 1906 both biological and chemical work on chemotherapy was provided for in the new Georg-Speyer-Haus. Ehrlich's inaugural address, here published for the first time, related the origin of his interest in chemotherapy and long-cherished wish to devote himself to it, at last fulfilled. The first paper from the Speyer-Haus (1907) describes most of the phenomena of chemotherapeutic biology, which have since been very widely encountered with the various drugs, parasites and hosts investigated. One misses an English version of those two classics. Incidentally, an interesting light can be thrown on Ehrlich's attitude to matters of publication by a fact which does not come within the range of *The Collected Papers*, namely, that chemotherapeutic interference, discovered at the Speyer-Haus and demonstrated to him in 1907, was never published in his lifetime (Browning, *Ann. N.Y. Acad. Sci.*, 59, 204; 1954). More than one-third of the volume is occupied by the salvarsan drugs. Ehrlich's principle, "corpora non agunt nisi fixata", which pervaded his outlook on immunity, also inspired his views on chemotherapy—drugs which act on pathogenic organisms must combine with the latter through chemoceptors, which, however, have not yet been defined chemically. An addendum consists of tributes on the deaths of Ehrlich's intimate scientific associates, Weigert (his cousin), Albrecht, Koch, Bertheim and Apolant.

At last Ehrlich's theories and descriptions of his work in his own telling language are all easily accessible, with versions of a proportion of them also in English. Sir Henry Dale has introduced each volume with his brief and lucid surveys and perspectives. Many glosses also testify that the editors have performed their heavy self-imposed duty with high seriousness. They have aimed to ensure that Ehrlich's enormous versatility and range of understanding alike in biology and chemistry, the numerous departments of knowledge which he either created or immensely enriched and the genius immanent in his contributions both to science and practice, shall be conspicuous.

C. H. Browning

CALORIFIC VALUE OF GASEOUS FUELS

Gas Calorimetry

The Determination of the Calorific Value of Gaseous Fuels. By C. G. Hyde and M. W. Jones. Second edition, entirely revised and reset. Pp. vii+456. (London: Ernest Benn, Ltd., 1960.) 105*s*. net.

The subject of gas calorimetry is of great importance to the gas industry, both for the proper assessment of its thermal efficiency and to enable it to comply with its statutory obligations. Since 1932 the standard work on the subject has been "Hyde and Mills", and in view of developments within the past twenty-five years the appearance of a second edition, in which Mills's part is taken by M. W. Jones, is to be welcomed.

While the original plan of the work has been retained, the book has been largely re-written. Major Hyde was until recently controller of gas standards, and Mr. Jones is principal gas examiner under the Ministry of Power, so that the authors are well qualified to deal with their subject, and *Gas Calorimetry*, 1960, may be taken as a full, modern and authoritative exposition.

It is useful to find the fundamental theory of calorimetry and thermometry combined with its application to specific instruments in a book which, being thus broadly based, has educational as well as practical value.

The new edition welcomes fluorescent lighting for test rooms, and describes a mobile unit of value in a scattered area of supply. It considers the Hyde meter prover, and might perhaps have omitted the older and largely obsolete Harcourt prover. The Mark II Fairweather recorder is well described, though it is difficult for publication to keep up with development in this sphere. It is particularly useful to have a clear description of the Reineke calorimeter, which is of increasing interest now that liaison between the gas and oil industries is becoming so close. The very useful set of tables in the appendix has been extended, and the placing of references at the end of their appropriate chapters is an advantage.

There is a brief consideration of the combustion characteristics of gas, but in view of the growing importance of this subject a fuller treatment would have been of interest, and some description of modern methods for the direct recording of the Wobbe index would have been valuable.

There is still a good deal of descriptive matter about obsolete or obsolescent instruments, even when one allows for the valuable principles sometimes involved. Surely no one to-day uses—if indeed they ever successfully used—a Lupton water heater. Moreover, the devotion of forty-one pages to the Boys recording calorimeter, ingenious as it was and distinguished as was its inventor, seems rather excessive. Flame indicators, too, cannot be advanced seriously in 1960 as other than highly misleading instruments. One might also make a plea for the substitution of a more descriptive name than the time-honoured "Tabular Numbers" for gas volume reduction factors. After all, most numbers come from tables.

These are, however, minor criticisms. The format of the book is clear and convenient, and, with the exception of one or two poorly reproduced photographs and an illegible table on p. 74, the printing is excellent. "Hyde and Jones" is altogether a worthy successor to "Hyde and Mills" and will long form the indispensable vade-mecum of all who, whether from the official or works-control angle, are concerned with the measurement of the calorific value of gaseous fuels. Physicists unconnected with the gas industry will also find in it much of value, and if they are surprised to find that an apparently simple operation is fraught with so many pitfalls they will also find the solution to many of their gas calorimetric problems within its pages. R. J. H. BANKS

QUANTITATIVE MORPHOLOGY

Quantitative Zoology

By George Gaylord Simpson, Anne Roe and Richard C. Lewontin. Revised edition. Pp. vii+440. (New York: Harcourt, Brace and Company, 1960.) n.p.

THE first edition of this work was published twenty-one years ago at a time when zoologists, particularly those interested in morphology and systematics, rarely employed statistical methods. In the meantime, interest has tended to shift in many subjects from the individual to the population, with the consequence that the use of statistical methods is much more necessary. The original authors have been joined by Dr. R. C. Lewontin in producing a revised version which, while having the same general plan, is more lucid and has had some mistakes removed. A chapter on the analysis of variance has been added, and the methods given usually assume that a calculating machine is available. The text is essentially a detailed explanation of those elementary statistical methods which are likely to be useful to zoologists in general and taxonomists in particular. Many examples, mostly drawn from the vertebrates, are fully worked out so that no other statistical source would be required. The least mathematical of zoologists should be able to follow the arguments and thereafter apply the methods to his own work. The biological significance of parameters or tests of significance is indicated wherever it is known. The last two chapters deal with graphic methods and with the problems of growth, respectively.

The authors admit that there are now many more good books on biometry, statistics, and general quantitative methods than when this work was first published. The most cogent argument for a new edition was that the book was still in demand though out of print. It is also true that many statistical works, so far as they touch on biology, are biased in the direction of agriculture. It seems debatable, however, whether, in view of the large number of statistical texts available, it might have been possible to reduce this side of the work and to expand it in other directions. The subject of sampling in the actual circumstances of Nature is rarely adequately discussed, and yet it raises many difficulties, though perhaps more for the ecologist. The paragraph on the capture–recapture method is perhaps too short to be useful in view of the real difficulties in interpretation and the many possible modifications of the simplest theory. Possibly the negative binomial distribution might be worth discussing; at least the bibliography might include more references to works in which additional or more refined methods are described.

The great merit of the work as it stands is its lucidity, which in this particular subject is a transcendent advantage. Nearly all taxonomists will find something useful to them in one chapter or another and very little that they cannot understand. O. W. RICHARDS

SULPHATED POLYSACCHARIDES

Polysaccharides in Biology

Transactions of the Fourth Conference, May 21, 22, and 23, 1958. Edited by G. F. Springer. Pp. 326. (New York: Josiah Macy, Jr. Foundation, 1959.) 5.95 dollars.

THIS is the report of a conference held at Princeton, New Jersey, in May 1958 on the sulphated polysaccharides. There are seven chapters, each associated with a main speaker whose account is followed by a discussion and further contributions. The chapter headings are: chondroitin sulphates (K. Meyer), biology of chondroitin sulphates (R. H. Follis), heparin and related substances (M. L. Wolfrom), the mast cell (R. D. Higginbotham), biosynthesis of sulphated polysaccharides (H. Boström), synthetic non-biological sulphated polysaccharides (M. J. Shear) and sulphated polysaccharides of plants (L. Stoloff).

The style of the book is provocative, and there will not be many neutral opinions about it. As in other Macy 'multiprofessional conferences', the proceedings are reported verbatim, with a few afterthoughts interpolated into the text. To this reviewer the presentation, reading like a playscript, has many merits, but a few 'stage directions' in the way of sub-headings would be helpful. There are no sub-headings within the chapters, and, since these are up to 60 pages long, the index assumes a vital function, but even though this is 20 pages long, in the circumstances it is barely adequate. Moreover, the lack of subdivision makes it difficult to discover when the main speaker has finished, and the contents page gives no inkling that a second speaker may also have presented a lengthy description of his own work. In the chapter associated with Meyer's name, the main speaker in terms of continuous matter is in fact Jeanloz. A further general disadvantage is that this is a conference of experts, and definitions which would be out of place in the conference room are necessary to the less-specialized reader. A glossary would be helpful.

An advantage that could be legitimately expected of this type of presentation is that it should be available for printing as soon as the tape-recorder has yielded its secrets to the typewriter. It is surprising to learn from the publishers that 20 months elapsed between the conference and the book becoming available in January 1960. Much that was new at the conference has since been published elsewhere. Nevertheless, the authoritative nature of the papers and the importance of the subject will ensure for the book a wide sale and circulation, and the Macy Foundation is to be congratulated on its timely choice of the subject. The book is well-produced, attractively priced and contains very few errors.

W. J. WHELAN

POLYPEPTIDES ACTING ON SMOOTH MUSCLES

Polypeptides which affect Smooth Muscles and Blood Vessels

Proceedings of a Symposium held in London on 23rd and 24th March, 1959. Edited by M. Schachter. (Biological Council's Co-ordinating Committee for Symposia on Drug Action Series, Vol. 4.) Pp. xv + 336. (London and New York: Pergamon Press, 1960.) 50*s*. net.

THE Co-ordinating Committee for Symposia on Drug Action, under the chairmanship of Sir Charles Harington, has sponsored discussions at the Wellcome Building in London in the spring since 1955. The subjects of these symposia have been histamine, hypotensive drugs, 5-hydroxytryptamine, and quantitative methods in human pharmacology. The present book deals with the fifth of these symposia, and shows how much this subject has developed since 1953 when fifteen authors contributed to a meeting in Montreal and afterwards published their contributions in a book (*Polypeptides which stimulate Plain Muscle*. Ed. J. H. Gaddum. Edinburgh: Livingstone, 1955).

The structures of oxytocin and vasopressin were first announced at that earlier meeting; now it is possible to discuss the relation between the structure and action of a number of homologues. Oxytocinase has been estimated with an artificial substrate, and a separate vasopressinase has been found in the placenta. Substance *P* resembles these pituitary hormones in that it appears to be stored in nervous tissue, but its structure and function are still unknown. The structure of angiotensin was elucidated in 1956, and the actions of a number of homologues have now been measured, but there are still serious doubts about the relation of this substance to hypertensin.

Kallidin, bradykinin and other kinins form a group with very similar actions. The isolation of bradykinin and its composition in terms of amino-acids were announced at the meeting in 1959; the exact structure is now known.

The final session was devoted to anaphylatoxin, leucotaxine, exudin, globulins affecting permeability and the activation of large molecular substances by injury. Some of these latter substances are still not clearly defined and there is much more work to be done by the chemists who have already done so well in this field.

Some of these polypeptides are thought to play important parts in physiology and pathology. Vasopressin controls the excretion of water, and oxytocin controls the uterus and the breast. The kinins may be released to cause vasodilatation in active tissues. There is clearly much to be discovered about all these substances and every reason to expect that they will prove to be physiologically important.

The symposium was a success because it collected the leading authorities from all over the world. Owing to the generosity of the Wellcome Trust and Sandoz, Ltd., it was possible to invite contributors from the United States, Sweden, Switzerland, Germany and Austria.

The book gives an authoritative summary of work in this field. It has been edited by M. Schachter and is beautifully produced, but rather expensive. It did not appear until a year after the symposium on which it is based, but that was partly due to a printers' strike. It is likely to remain the best summary of work in this field for some time to come.

J. H. GADDUM

SEDIMENTARY ROCK TYPES

Microscopic Sedimentary Petrography

By Prof. Albert V. Carozzi. Pp. viii + 485. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1960.) 92*s*. net.

THE work of Prof. Albert V. Carozzi is well known to geologists by the publication in 1953 of his *Petrographie des Roches Sedimentaires* and by other important papers. Here he describes his work and that of others in English. Throughout the book the author refers to both American and European examples, and the long list of references at the end of each chapter is by no means the least valuable part of this important book. No attempt is made to confuse the student with a wealth of individual examples, but rather to describe ideal types together with the chief variations. From such descriptions it is a relatively simple matter for the research worker to apply such general principles to his own particular problems.

The author divides the sedimentary rocks into three main groups, namely, the clastic, the biochemical and the chemical rocks. The first and last groups are well known to students, but the middle division is less familiar. Under this heading are described carbonate, siliceous, iron-bearing and phosphoritic rocks which possess the common property of having been generated chiefly by organic as well as chemical processes.

In Part 1 the microscopic characters of the clastic rocks are dealt with under the headings of arenaceous, rudaceous, pyroclastic and argillaceous rocks. Microscopic definitions are reduced to an absolute minimum, and in this as in succeeding sections of the book the author directs attention to the great amount of additional knowledge which is still required for a complete understanding of the genesis of many sedimentary rocks.

Part 2 deals with the biochemical rocks, and an evaluation of the relative value of the two processes —organic and chemical—is attempted.

In the concluding part the evaporites are described. These are, perhaps, among the most difficult of all sedimentary rocks to understand, and the author has wisely not theorized further than published descriptions enable him to do so.

Prof. Carozzi's chief interest has always centred on the carbonates, and the many workers in this field will find much of value in his able summary concerning the formation of the oolites and dolomitization.

The book concludes with extensive author and subject indexes, and is well produced on good paper with a pleasing type, though it is unfortunate that it was necessary to price it rather on the high side.

F. S. WALLIS

Mineral Processing

By Dr. E. J. Pryor. Revised and enlarged edition of "An Introduction to Mineral Dressing". Pp. vi+814. (London: Mining Publications, Ltd., 1960.) 90*s*.

THE second edition of Dr. Pryor's book, under a new title, is a revised, extended and improved version of the first. All the illustrations now have captions, it is less pedantic in places and there are improvements in detail of presentation, but some of the criticisms in the notice of the first edition (*Nature*, 177, 908; 1956) are still valid.

Although, as stated on page 3, "Mathematical presentation has been avoided as far as possible in this book", more formulæ are used in the new edition than in the first, but, when they are given just as formulæ, they do not always help the generally empirical approach (which may lead to undue wordiness) in the way that they should. Such mathematical approaches as are used are spoilt by the haphazard use of symbols. Specific gravity and density (no units given) are used indiscriminately and their symbols may be δ, Δ, ρ, γ, or S. The symbol S is used also for the thickness of the double layer, for entropy, for specific surface and for the 'set' of crushing rolls. The symbol R is used for six different purposes and other symbols have multiple uses—one of them for two purposes on the same page. The formula for Reynolds number appears in two places: in one V is velocity, $2r$ is diameter and δ is density; in the other v is velocity, δ is diameter and ρ is density.

The chapter on the physics and chemistry of pulps has been considerably improved; so has the chapter on coal preparation but perhaps not as much as its importance warrants. The chapter "Gold Cyanidation" has been replaced by a chapter "Chemical Extraction" which devotes 58 pages to gold but only an inadequate 14 to "other metals and minerals".

The book as a whole is well arranged and contains a great deal of information, perhaps too much in connexion with details of process and plant operation, some of which might well be omitted in a new edition and the space so released used for more rigorous mathematical approaches to those problems which lend themselves to such treatment. S. G. WARD

Demineralization by Electrodialysis

Edited by J. R. Wilson. Pp. xv+378. (London: Butterworths Scientific Publications, 1960.) 60*s*.

IN 1959, the world's largest electrodialysis plant came into operation at the Free State Geduld mine in South Africa. This plant, with a design capacity of 2,400,000 gallons of desalted water a day, was the outcome of a programme of research and development in the laboratories of the South African Council for Scientific and Industrial Research. This book by the staff of the Process Development Division of the Council's National Chemical Research Laboratory, is a review of the process of demineralization by electrodialysis, and also a technical record of the various stages in the development and construction of the largest electrodialysis plant which has so far been built. The book contains chapters on the electrodialysis process, the physical chemistry of ion-selective membranes, the preparation and characterization of membranes, the design and operation of electrodialysis plant, pilot-plant operations, and the Free State Geduld electrodialysis plant. The later chapters, which include details of the difficulties encountered in the preparation of the ion-selective membranes and in the construction and operation of the plant, will be of value to all who are concerned with the practical application of electrodialysis to water desalting. The earlier chapters will be of wider interest. The book contains a great deal of useful information and is supplemented by a comprehensive bibliography. The index is a little difficult to use, but otherwise the book is well produced, with very good illustrations and diagrams.

D. K. HALE

On Mathematics and Mathematicians

By Robert Edouard Moritz. (Formerly titled "Memorabilia Mathematica or the Philomaths's Quotation Book".) Pp. vii+410. (New York: Dover Publications, Inc.; London: Constable and Co., Ltd., 1958.) 1.95 dollars; 16*s*.

THE publishers of paper-back reprints are not always happy in their choices, but only the very hard-hearted reader will refuse a welcome to this reprint of the "Philomaths's Quotation Book", long out of print and almost unobtainable. From more than 2,000 quotations we can select informed and ill-informed attempts to define mathematics, we can read what Gauss and Henry Smith have said about the theory of numbers or what Condamine said about the Yancos of the Amazon, whose name for three is 'poettarrarorincoaroac': "Heureusement, leur arithmétique ne va pas plus loin". The Sylvester anecdotes alone are worth the price of the book. An excellent bed-side volume; but it has a deeper value How many of the judgments and opinions which were acceptable in 1914 retain their full worth to-day? If Moritz could give us a 1960 collection of "great thoughts", with quotations from Bourbaki, Brouwer, Hardy, Hogben, Hilbert, Weyl, to name only a few, would the comparison not show a difference in tone and values enough to indicate a profound revolution in our ways of thinking about mathematics? Would it be Trollope against Graham Greene? Theses have been written on less interesting themes.

T. A. A. BROADBENT

Handbook of Geophysics

Revised edition. (United States Air Force/Geophysics Research Directorate.) Pp. xvii+657. (New York and London: The Macmillan Company, New York, 1960.) 105*s*.

BY means of excellent diagrams and detailed tables this volume summarizes our knowledge of that part of geophysics concerned with phenomena above the Earth's surface. Much of the information is intended for the engineer designing aeroplanes and rockets; but the compilation will be of great value to the scientist and of considerable interest to the general reader. For example, the chapter on clouds, which gives tables showing the frequency of various ceiling heights of cloud at various places, provides very interesting reading.

There are chapters on the divisions of the atmosphere, its temperature, density and pressure distribution, a discussion of winds, including data on the jet stream, data on the rain and hail distribution and on the composition of the atmosphere. There are charts of the Earth's magnetic field and data on magnetic activity and atmospheric electricity. Basic information on geodesy is given and thermal and cosmic radiation discussed. The propagation of light, electromagnetic radiation, and sound through the atmosphere is another topic, and there is a very useful chapter on devices for exploring the atmosphere. In places, the writing leaves something to be desired; for example, meteors are defined as "extraterrestrial matter which have penetrated far enough into the earth's atmosphere to become embroiled in a violent reaction with it". S. K. RUNCORN

A Bibliographical Index of the British Flora

Including Floras, Herbals, Periodicals, Societies and References relating to the Identicfiation, Distribution and Occurrence of Phanerogams, Vascular Cryptogams and Charophytes in the British Isles. Compiled by N. Douglas Simpson. Pp. xix+429. (Bournemouth: N. Douglas Simpson, 3 Cavendish Road, 1960.) n.p.

THIS is an ambitious effort to index references concerning the identification, history and geographical range of the flowering plants, vascular cryptogams and charophytes in the British Isles, including Ireland. It also attempts to provide information on plant-lore, local names, poisonous plants and weeds. To accomplish thoroughly such a task would be a prodigious undertaking requiring detailed scrutiny of the vast literature in which records may be expected. It is not surprising, therefore, that the present work is admittedly incomplete, with many publications of local societies and other sources entirely unexamined. The format of the book is unnecessarily elaborate, with the entries, many of them of trivial scientific significance, arranged in a complicated and indeed irksome sequence. Any attempt to give a complete list of species records under the various counties would be a colossal and forbidding task for any individual, and in this volume it seems ill-advised and redundant to include quite an arbitrary selection of such records. The work is undoubtedly the product of great industry and within its limits will certainly be a useful adjunct in the study of the British flora. G. TAYLOR

Founders of British Science

John Wilkins—Robert Boyle—John Ray—Christopher Wren—Robert Hooke—Isaac Newton. By J. G. Crowther. Pp. ix+296+10 plates. (London: The Cresset Press, 1960.) 35*s*. net.

IT is greatly to be hoped that no one will be misled by the title of this book: it is neither an attempt to establish an exclusively 'British science' on the model of the 'Aryan science' of the 'thirties, nor dogmatically to exclude other claimants to the title of its 'founders'. Mr. Crowther's preliminary chapter emphasizes the importance of Gilbert, Napier, Harriot, and Harvey in the 'gestatory period' of British science; indeed, as scientists, all four of these men might be held to be of greater stature than Wilkins. But 'science' for Mr. Crowther, as he has made abundantly clear in earlier writings, is no isolated activity to be followed at the beck of individual whim and genius, but is 'wholly' effective only when the course of its progress is in harmony with social needs. To illustrate this anew, he has examined with great thoroughness the contemporary sources which shed light not only on the scientific achievements of the six well-chosen 'founders' of 'organized' British science, but also on their social circumstances, aspirations, frustrations, and insight into contemporary needs In a wide-ranging survey of such a controversial question it is inevitable that the account of the facts, and even more of some of the inferences drawn from the facts, will not pass unchallenged; in pressing the argument too hard, the author is sometimes even landed in inconsistency. Also the 'close naked style', which would have pleased his hero, Wilkins, makes some of Mr. Crowther's statements appear more dogmatic than he perhaps intended. But the great virtue of his book is that, apart from its assemblage of a great deal of significant but widely scattered information, it is provocative in the best sense. It is not necessary to go the whole way with Mr. Crowther to welcome his presentation of the thesis that scientists no longer (if they ever did) pass their lives in some empyrean realm in selfless dedication to the pursuit of ultimate truth.

W. P. D. WIGHTMAN

Food Chemistry

By Prof. Lillian Hoagland Meyer. (Reinhold Organic Chemistry and Biochemistry Text-book Series.) Pp. xiv+395. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1960.) 65*s*. net.

PROF. MEYER states in her preface that the aim of her book is to provide a unified picture of foods from a chemical point of view. To this end the emphasis is on the composition of foods and the changes that occur when they are subjected to processing. The book is intended for students who have been trained in organic chemistry, but some chemical background is provided to clarify details of methods of analysis and identification. The book is descriptive rather than didactic in relation to practical work in food chemistry and is not therefore suitable as a laboratory manual. It does, however, provide a readable survey of the nature of fat, carbohydrate and protein components of common foods with additional chapters on flavour and aroma, on meat and meat products, vegetables and fruits, milk and milk products and on cereals. An appendix gives an account of food additives permitted by the most recent lists of the U.S. Food and Drug Administration. A. M. COPPING

Sampling Inspection Tables

Single and Double Sampling. By Harold F. Dodge and Harry G. Romig. Second edition, revised and expanded. (Wiley Publications in Applied Statistics.) Pp. xi+224. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 64*s*. net.

SINCE the first edition of this book appeared in 1944 it has been one of the most useful sets of tables for scientific sampling inspection. This new edition, on a much larger page, has grown almost out of recognition, mainly because of the addition of a set of diagrams of operating characteristic curves. The four chapters which precede the tables are themselves a valuable introduction to the theory and method of sampling inspection. After these one finds the curves and sampling tables for specified lot tolerance per cent defective and average outgoing quality limit, both for single and for double sampling plans. There is also (an unusual feature in tabular material) a useful index. This is an essential book for the serious student and the factory operator, written with the authority of long experience in teaching and practical application.

M. G. KENDALL

BIOCHEMISTRY OF HEREDITY: A GENERAL HYPOTHESIS

By DR. IAN LESLIE

Biochemistry Department, Queen's University, Belfast

(I) BIOCHEMICAL RELATIONSHIPS BETWEEN DEOXYRIBONUCLEIC ACID, RIBONUCLEIC ACID AND HISTONES

BECAUSE of major advances in biochemistry during the past ten years, it is now possible to think of the transfer of hereditary characteristics from parents to offspring in chemical terms. The landmarks of progress in this direction are: (1) the realization that deoxyribonucleic acid (DNA) is the primary genetic substance of all cellular organisms[1,2], and (2) the construction by Watson and Crick[3] of a molecular model of DNA, the reality of which now appears to be established[4,5]. The structure is unique, consisting of two complementary polynucleotide strands, linked together by hydrogen-bonding between the base pairs, adenine (A) to thymine (T), and guanine (G) to cytosine (C).

Other vital discoveries concern the function of ribonucleic acid (RNA), which, in contrast to DNA, is not confined to the chromosomal elements of the cells but is spread throughout the nuclear and cytoplasmic regions. The RNA molecules, like those of DNA, are now known to carry genetic information as single-stranded polynucleotides within the sequence of bases A, U (uracil), G and C. This has been demonstrated unequivocally by the discovery that the chemical alteration of the bases in RNA from tobacco mosaic virus produced a mutant virus, in which the protein had a distinctive amino-acid composition[6].

In cellular organisms it is believed the single-stranded template RNA, located in the ribosomes, directs the synthesis of the cell-specific proteins. The association between RNA and protein synthesis has been recognized for some time[7,8]; but its exact role only became known in recent years, largely through the work of Zamecnik, Hoagland and their colleagues[9-11]. Protein synthesis begins with the 'activation' of the amino-acids to produce their adenylate-enzyme complexes which then link the amino-acids to specific 'transfer' RNA molecules. This form of RNA (known as soluble or transfer RNA) is believed to direct the amino-acids into their particular sequence along the *template* RNA[10,12]. The coding operation almost certainly depends on the hydrogen-bonding of the base-pairs, A to U and G to C, but the discovery of the cipher for each amino-acid remains one of the crucial problems of current research (cf. 13, 14).

The Genetic Problem

The present article is concerned solely with the exchange of genetic information between DNA and RNA, and with the mechanism which decides whether the information will be expressed or suppressed in the differentiated cells of higher organisms.

Crick has defined the problem in straightforward and lucid terms[12]. His "central dogma" is that "the transfer of information from nucleic acid to nucleic acid, and from nucleic acid to protein may be possible, but the transfer from protein to protein or protein to nucleic acid is impossible". This is almost universally accepted, as is the concept that RNA is the messenger which carries information from the DNA of the chromosomes to the metabolic regions of the cells. In Crick's terms, the four-letter code given by the bases A, T, G and C has to be translated through RNA to form the twenty-letter amino-acid sequences, which endow proteins with their specific functions. The key to this genetic code lies, therefore, in the base composition of the messenger or *template* RNA, which, by all indications, is produced as single-stranded polynucleotides on the DNA 'master-genes'[14-16].

New information, obtained initially from cultures of human liver cells, has made it possible to formulate a general hypothesis of genetic coding and cellular differentiation. The hypothesis is presented at this stage with the minimum of elaboration. Essentially, there are three main concepts:

(1) Two genetic codes for RNA formation are operating in Nature—one in certain micro-organisms, another in the somatic cells of higher organisms.

(2) Histone proteins act as gene regulators by their ability to 'stabilize' one polynucleotide strand and depolymerize or 'disjoint' the complementary strand which is derived from the 'soluble' or 'transfer' RNA.

(3) In the differentiated cells of higher organisms, part of the histone allows the RNA templates to act as protein synthesizers; another form of histone, located in the nuclei, has the function of suppressing the template function of the associated RNA.

The Base Composition of Template RNA

Human liver cells (strain *HLM*) have been cultured in sufficient amounts for their fractionation into nuclei, combined particles (nuclei, mitochondria, large microsomes), and ribosomes. The nuclei were cleaned by treatment with 0·25 M sucrose, 0 01 M citric acid at pH 3, and the combined particles were spun down at 18,000g for 30 min. from 0·44 M sucrose buffered at pH 7·4. The ribosomes were obtained by treatment of the microsomal pellets with surface-active agents in sucrose medium and sedimentation at 105,000g for 2 hr. The determination of base ratios in RNA and DNA gave the following information, which will be published in greater detail elsewhere[20].

(1) The mean DNA base composition, A : T : G : C is 30 : 30 : 20 : 20 and close to the values previously found for human cells[21].

(2) The total RNA of the combined particles has base ratios for A : U : G : C equal to 19 : 18 : 31 : 32.

(a) Duplex DNA	Per 100 bases	(b) Duplex RNA	Per 100 bases
-A—T-	30 A	-A—U-	19 A
-T—A-	30 T	-U—A-	18 U
-G—C-	20 G	-G—C-	31 G
-C—G-	20 C	-C—G-	32 C
	(determined)		(determined)

(c) RNA isolated from nuclear fraction*

RNA template	RNA second strand	Hence duplex RNA	Per 200 bases	Per 100 bases
24 -A	24 -U	24 -A—U- 24	39 A	19·5 A
15 -U	15 -A	15 -U—A- 15	39 U	19·5 U
37 -G	37 -C	37 -G—C- 37	61 G	30·5 G
24 -C	24 -G	24 -C—G- 24	61 C	30·5 C
(determined)	(deduced)			

* Substitution in the 'RNA template' column of the ratios A : U : G : C = 14 : 25 : 48 : 13, obtained for the RNA of acid-extracted combined particles, gives the same values in the last column.

Fig. 1. The base compositions of duplex forms of DNA and RNA and their relationship to single-strand RNA isolated from human liver cells (*HLM* strain)

These may reasonably be called the inverse of the DNA ratios ; ideally, they would be 20 : 20 : 30 : 30. For convenience, such base compositions in which A = T or U and G = C will be called 'symmetrical'.

(3) Extraction of the combined particles with ice-cold dilute sulphuric acid removed histone protein and about 50 per cent of the original RNA. The composition of the residual RNA was found to be radically changed from the symmetrical pattern of total RNA. The ratios A : U : G : C of 14 : 25 : 48 : 13 are surprisingly close to those of post-microsomal RNA's isolated from guinea-pig pancreas[22].

(4) For the total RNA of citric acid-washed nuclei the base ratios are 24 : 15 : 37 : 24 and are almost identical to values for RNA isolated from rat-liver ribosomes and purified by column chromatography on 'Ecteola' cellulose[23]. Ribosomal RNA from *HLM* cells also has an 'asymmetrical' composition (19 : 18 : 36 : 27).

(5) Acid extraction of histone protein from nuclear and ribosomal fractions caused no loss of RNA and scarcely any change in the asymmetrical base ratios.

The interpretation of these results is given diagrammatically in Fig. 1. The symmetrical ratios for DNA are a recognized feature of its duplex structure (Fig. 1*a*). It is proposed that the symmetrical ratios for total RNA in the combined particles are a consequence of its duplex form in these preparations. The asymmetrical RNA's, on the other hand, are thought to be different molecular populations of *single-stranded template* RNA. If this proposition is correct, the duplex base ratios derived from them arithmetically should be the same as those found for total RNA in combined particles. These are calculated for nuclear RNA (Fig. 1*c*), on the assumption that A bonds to U and G to C. The agreement between the deduced values and symmetrical RNA (Fig. 1*b*) is, in fact, found to be very close.

With the knowledge that the duplex and single-stranded forms of RNA can be isolated by appropriate procedures, and can be recognized by the symmetry or the particular asymmetry of the base compositions, it has been possible to detect these two forms of RNA in the results of other investigators. In some instances, the conclusion that the RNA has been isolated as single-stranded polynucleotide is associated with metabolic evidence suggesting its template function[22,24,25].

Transfer of Template RNA from Nucleus to Cytoplasm

In the present work with human cell cultures, it has been possible to show that the asymmetrical or template RNA is produced in the nucleus and moves to the cytoplasm during interphase. This transfer is a vital feature of present concepts of genetic coding and has been studied intensively in recent years (cf. ref. 26). The movement of RNA from nucleus to cytoplasm has already been made visible in human cells by labelling the nucleic acid with tritiated-cytidine and applying the autoradiographic technique to the coverslip cultures removed at intervals over the subsequent twenty hours[27]. However, in these circumstances, the labelled polynucleotide could consist of both the template and 'transfer' parts of RNA. This doubt has been eliminated by labelling the nucleotides with phosphorus-32 and isolating them from the asymmetrical RNA's prepared from the nuclear and ribosomal fractions.

The discovery that 5-fluoro-2-deoxyuridine inhibits DNA synthesis without immediate effect on RNA formation makes it possible to block mitosis and keep the majority of the cells in the interphase state[28]. Preliminary tests showed that RNA and protein in the *HLM* cell cultures would increase by about 50 per cent in 24 hr., without any concurrent increase in DNA formation. With this experimental system, the changing pattern of labelling in the RNA nucleotides was followed in the nuclear and ribosomal fractions at different times after the cells had been in contact with isotopic medium for one hour. The isotopic medium was completely removed, and the cells continued to metabolize in the 'cold' medium, which was replaced again one hour later to reduce still further the metabolic pool of radioactive phosphate.

The first obvious feature of the labelling was that the specific activities of the RNA nucleotides from the nuclei were four times those of ribosomes at one hour and they were still twice as high at ten hours. After 24 hr. the levels of radioactivity were the same in all fractions. This rapid labelling of nuclear RNA, followed by a gradual levelling-out of the difference between nuclear and ribosomal RNA, is a well-established sequence of events in animal cells[29]. However, unless the labelled nucleotides are known to come from asymmetrical template RNA, it is not possible to conclude from the prior labelling in the nuclei that it eventually moves to the cytoplasm.

When it was realized that RNA had been isolated in template or near-template form (as in ribosomes), the change in pattern of the labelling of the nucleotides with phosphorus-32 with time became understandable. The results of two tests are shown in Table 1. As the specific activities are all expressed relative to the value of 100 for adenine, the more rapid labelling of the nuclear RNA is concealed. The values are intended to emphasize important differences between the related nucleotides, adenylic acid and guanylic acid on one hand, and between uridylic acid and cytidylic acid on the other. It is seen that specific activities are always higher for adenylic acid and uridylic acid than for guanylic acid and cytidylic acid, and that the ratios, adenylic : guanylic and uridylic : cytidylic are greatest in ribosomal RNA at the short labelling-time of one hour. By comparison, the corresponding ratios for nuclear RNA are nearer unity or 'less asymmetrical' at each time of sampling.

The interpretation of these results rests on the knowledge that, in the synthesis of purine nucleotides,

Table 1. EVIDENCE FOR THE MOVEMENT OF TEMPLATE RNA FROM THE NUCLEUS TO CYTOPLASM DURING INTERPHASE IN CULTURES OF *HLM* CELLS

Source of RNA	Duration of phosphorus-32 metabolism* (hr.)	Relative specific activities of nucleotides (Adenylic acid = 100 counts/min./10 μgm.P)			
		Adenylic acid	Uridylic acid	Guanylic acid	Cytidylic acid
Nuclei	1	100	108	84	85
Ribosomes	1	100	130	49	51
Nuclei	6	100	119	105	108
Ribosomes	6	100	99	66	75
Nuclei	10	100	106	97	94
Ribosomes	10	100	114	87	86
Ribosomes	23	100	109	98	97

* The culture medium contained 0·1 μgm. 5-fluoro-2-deoxyuridine/ml. from 4 hr. before inclusion of 5 μc. $^{32}PO_4$/ml. for a period of 1 hr. Isotopic medium was replaced by non-isotopic medium at 1 and again at 2 hr., and the cells were harvested at times indicated.

adenylic acid precedes in time guanylic acid, and in the synthesis of pyrimidine nucleotides, uridylic acid precedes cytidylic acid[29–31]. This should lead to an initial unevenness of nucleotide labelling which can be expected to disappear when equilibrium with radioactive inorganic phosphate is achieved. (This is found even when the RNA is degraded to 2′(3′)-nucleotides, since in asymmetric RNA there is at least 60 per cent of guanine and cytosine.)

The only likely explanation which can reconcile the coincidence of faster labelling of nuclear RNA with greater asymmetry of radioactivity within ribosomal RNA is that template RNA is formed within the nucleus and moves out to the cytoplasm. The gradual progression towards uniform labelling of nucleotides in both fractions as time proceeds is fully consistent with this interpretation.

Ribonuclease Activity of Histone Protein

The most remarkable feature about histone protein has been the lack of information about its metabolic or enzymic activity. (This was justifiably said of the nucleic acids less than ten years ago (cf. ref. 12).) It has long been recognized as the companion-protein of DNA in animal and plant cells, and the view is still held that histone, like DNA, is confined to the cell nucleus. The one role which has been consistently claimed for it is that the β-histone from nuclei is cell-specific and acts as a gene-inhibitor[32,33]. This has remained hypothetical, because the concept depended on observed differences in composition and electrophoretic behaviour of the proteins rather than on the demonstration of their mode of action.

Within the past two years, the presence of histone-like protein has been confirmed in the ribosomes prepared from animal and plant cells[34–36], and is reported in the smallest ribosomes from *Escherichia coli*[37]. When it became apparent that histone might not be confined to the nucleus, an investigation was begun on its distribution between the nuclei and ribosomes of *HLM* cells. The protein was extracted with ice-cold 0·5 *N* sulphuric acid and precipitated with ethanol[38], before being purified by column chromatography on carboxymethylcellulose (Whatman)[39]. This work was later extended to the histones of guinea pig liver, and the new information which it yielded is now briefly summarized.

(1) The amino-acid composition of the acid-extracted protein from ribosomes of *HLM* cells was shown by paper chromatography to be similar to that of histone[40]. The average arginine concentration was 16 per cent.

(2) The nuclear histones from both *HLM* cells and liver produced four fractions in the eluent from the column. Fraction I was largely polynucleotide material; II, III and IV were histones. Fraction III was arginine-rich (average 22 per cent) and it probably corresponds to the β-histone of Cruft, Mauritzen and Stedman[33].

(3) By contrast, the ribosomal extracts from both *HLM* cells and liver produced only three peaks, corresponding to I, II and IV above. It can be concluded that only histones II and IV are associated with the template RNA which moves from the nucleus to cytoplasm. The profiles of ribosomal and nuclear histones isolated from *HLM* cells are shown in Fig. 2.

There were a number of reasons for proceeding to test the eluted histones for their ribonuclease activities. Chief among them were the reports that highly purified ribosomes contained latent forms of this enzyme, which became active only on releasing the protein from its associated RNA[41,42]. It was also observed that the profiles for the ribosomal histones were similar to those for ribonuclease released from pancreas microsomes by dilute sulphuric acid and separated by column chromatography[43]. The following results were obtained with histones from *HLM* cells and guinea pig liver[44].

(4) Each histone peak from the nuclear and ribosomal preparations showed ribonuclease activity towards yeast RNA[45]. The activities of nuclear histones were higher at *p*H 7·8 (alkaline histone-ribonuclease) than at *p*H 5 (acid histone-ribonuclease), in general agreement with earlier observations on the total enzyme activity in liver nuclei[46]. With the ribosomal histones from *HLM* cells, depolymerization occurred at *p*H 7·8, but the same protein showed virtually no activity at *p*H 5; Tashiro[42] and Roth[47] both report that ribosomes contain latent alkaline

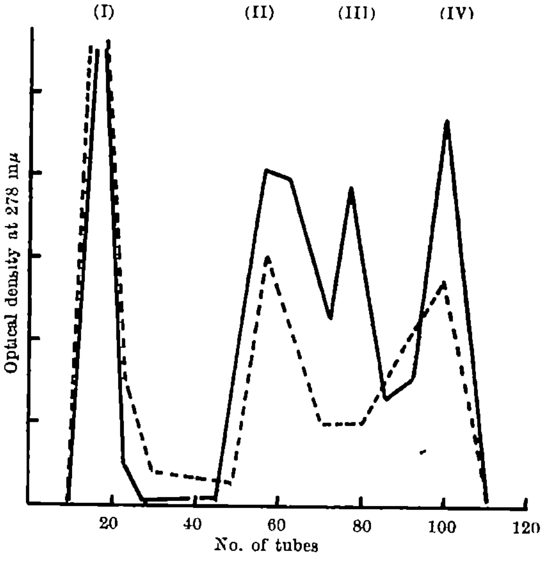

Fig. 2. Histones of human liver cells (*HLM* cells) fractionated by gradient elution from 10-cm. columns of carboxymethylcellulose (Whatman) —, nuclei; – – –, ribosomes

but not acid ribonuclease. The distribution within these cells of the histone-nucleases with these *p*H optima has still to be fully delineated.

(5) Ribonucleic acid, prepared from guinea pig liver, showed no depolymerization at *p*H 5 in the presence of excess of the combined nuclear histones from this organ. (Excess of histone is present in the assay when there is more than one histone amino-acid for every nucleotide in the substrate RNA.) The same RNA preparation, which had been purified by removal of nucleotide material soluble in ice-cold *N* perchloric acid in 1 hr., was depolymerized by bovine pancreatic ribonuclease and by *HLM* nuclear histone under identical conditions. Confirmation of enzymic activity of the nuclear histone was obtained concurrently with yeast RNA, likewise purified by mild perchloric acid treatment.

(6) The above observations on histone-nuclease activity are found to depend on the presence of sodium chloride of between 0·05 and 0·3 *M* in the assay medium. Further work on the effects of sodium, potassium and magnesium ions is necessary for a proper understanding of histone-nuclease action.

(7) As regards the nature of the specially prepared RNA used in these tests, there is sufficient evidence, based upon the recognition of the base compositions of single-strand and double-helix RNA, to indicate that it is the single-strand, template form of the nucleic acid.

This work on the interaction between histone fractions and RNA from different sources is continuing, but it already shows that histones can act as depolymerases towards RNA, if the RNA is not their associated template form. Their stabilizing action towards template RNA is indicated by the absence of any breakdown when homologous RNA was incubated with excess of the combined nuclear histone in the absence of saline and magnesium ions. This suggests that RNA is stabilized by histone when the ionic conditions promote bonding between the RNA and histone moieties.

Genetic Function of Histone-nuclease

It is proposed that each RNA template has specific stabilizing histones, which can act as depolymerases towards polyribonucleotides of different base composition. Experimental support for this concept is implicit in the present results and in three illuminating papers on the latent ribonuclease activity in ribonucleoproteins[42,47,48]. There are also such clear-cut distinctions between the effects on 'synthetic' polyribonucleotides as the ability of bovine pancreatic ribonuclease and an alkaline ribonuclease from rat liver to degrade polyuridylic acid but not polyadenylic acid[49]. The more subtle aspects of the inverse behaviour of different nucleases have been described by Hilmoe[50].

Logically, it is a short step from this view of histone-ribonuclease action to the concept that each stabilizing histone of single-strand template RNA is the depolymerase for its complementary strand formed during protein synthesis. Although a reasoned case could be made for this particular 'all-or-none' action of ribonuclease, it would be premature to do so until it is known whether the minor nucleotides (pseudouridine, 5-methylcytosine, 6-methylaminopurine, etc.), found mainly in soluble RNA[51], are also part of the complementary strand.

It is postulated that histones, like template RNA, are formed on the DNA genomes and may have the function of stabilizing the RNA templates while acting as depolymerases towards the complementary strands. If separated from the RNA, they will depolymerize any unprotected RNA molecules of different base composition. It follows that the association of nucleic acid with specific histone-nucleases[48] may be the means of suppressing the continuity of the polynucleotide strands which would pass on the 'wrong' information in protein synthesis.

Stent[52] has discussed this problem of 'active' and 'passive' strands in relation to genetic coding systems, and from Hotchkiss[53] has come the suggestion that "theories of DNA replication should take into account the enormous stability that one single-helix running in one direction could have towards an enzyme actively engaged in exchanging base residues at the end of a chain which is being synthesized in close proximity along an opposite direction". These concepts form an integral part of the hypothesis that there are in existence two coding systems for exchanging genetic information between DNA and RNA.

(2) GENETIC CODING SYSTEMS IN CELLS AND VIRUSES

Four coding systems have been proposed for the transfer of genetic information from DNA genomes to the RNA templates required for protein synthesis[52,54–56]. All involve the assumption that the purines and pyrimidines *or* their base-pairs, A–T and G–C, along the DNA chains determine the base sequence in the derived single-strand RNA. The ciphers for these codes are shown in Table 2. Three envisage the formation of RNA on duplex DNA and the fourth adopts RNA base-pairing rules, analogous to those in DNA, for producing an RNA strand from a single gene-strand. This last code is attributed to Rich[55], as he has presented the case for it in some detail.

Zubay[54] and Sinsheimer[56] developed their coding systems from the observation of certain trends in the base compositions of RNA and DNA in metazoan and unicellular organisms. The basis of Zubay's code is the near-equivalence in animal cells of the ratio $(G + C)/(A + U)$ in nuclear RNA with the ratio $(A + T)/(G + C)$ in the associated DNA. This led him to propose that the base-pairs A—T and T—A locate either cytosine or guanine on single-strand RNA, according to their orientation along the double-helix; similarly, G—C and C—G locate the position of the bases adenine and uridine, and thus determine the sequence along the RNA strand. The four possible arrangements of this coding system are given in Table 2.

Sinsheimer's coding system was designed to reconcile the paradox of the apparent co-existence of DNA of widely different composition with RNA of more uniform composition in a range of bacterial organisms. Essentially, his system allows the base-pair C—G to be substituted for A—T without altering the base sequence of the derived RNA. Again there are four possible combinations of this code, as shown in Table 2.

The individuality of the coding systems of Rich and Stent[52] lies in the manner of their operation. Stent envisages the growth of RNA as a third strand in the deep groove of the DNA duplex, while Rich

Table 2. POSSIBLE CODING SCHEMES FOR THE TRANSFER OF INFORMATION BETWEEN DNA AND RNA

Coding system	Proposed rules*	Possible combinations for transfer. DNA to RNA. RNA bases: Adenine	Uracil	Guanine	Cytosine
Duplex: DNA to single-strand RNA	*Zubay* (ref. 54) *AT* or *TA* gives G or C *GC* or *CG* gives A or T	(*a*) GC	CG	AT	TA
		(*b*) CG	GC	TA	AT
		(*c*) GC	CG	TA	AT
		(*d*) CG	GC	AT	TA
	Stent (ref. 52) As in next column	TA	AT	CG	GC
	Sinsheimer (ref. 56) *AT*/*CG* give G/U or A/C *TA*/*GC* give C/A or U/G	(*a*) TA	CG	AT	GC
		(*b*) AT	GC	TA	CG
		(*c*) CG	TA	GC	AT
		(*d*) GC	AT	CG	TA

* Italics indicates DNA base-pairs.

suggests, for stereochemical reasons, that a single strand of RNA could form on a strand of DNA, producing a transient hybrid molecule. Both these codes have a single cipher for the four RNA bases by which, for example, A and A—T locate the position of uridine in the RNA strand. They adhere, in effect, to the hydrogen-bonding rules for the DNA duplex.

A vital difference underlies this similarity in their 'message'. In the single-strand system of Rich, each strand from duplex DNA should be capable of producing an RNA template. Owing to their opposite polarity, these strands would carry contradictory information to the sites of protein synthesis. Either the concept of 'active' and 'passive' DNA strands must be invoked[52], or a mechanism must exist for suppressing one template while eliciting the expression of the other.

Conditions for Testing Genetic Coding Systems

Knowing the base compositions of single-strand RNA and the conditions for isolating it in this form, it is possible to test the validity of these four coding systems. Thoroughly rigorous criteria for such tests would require:

(1) Independent confirmation that the template RNA was single-stranded by physicochemical studies or by the demonstration of its ability, when in ribosomes, to direct specific protein synthesis.

(2) The isolation from the same tissue of RNA in its double-helical form, and the knowledge that its base composition agrees with the duplex ratios calculated from the single-strand or asymmetric RNA as shown in Fig. 1.

(3) An established base composition for the DNA of the species.

For the present, it is not possible to satisfy fully these conditions. Since the hypothesis is intended to lead to experimentation and discussion, it will be developed from the available information.

Table 3 gives the base compositions of RNA and DNA from human cells, rat liver and pea seed roots. The reasons for the assumption that two RNA complexes have been isolated from the human liver cells in their single-strand form are given above. The extent of the base-ratio asymmetry can be judged from the factor in the second-last column of Table 3. This increases as the numerical gaps between adenine and uridine, and between guanine and cytosine, widen. The values of the factors are, of course, very low or zero in duplex forms of RNA and DNA.

The base ratios for single-strand RNA of rat liver are those of RNA II isolated by column chromatography on 'Ecteola' cellulose by Goldthwait[23], who observed that it was similar to post-microsomal RNA and did not act as 'transfer' RNA, unlike the accompanying RNA. It is seen that the duplex composition, calculated from the base ratios of RNA II, resembles closely a determined symmetrical RNA, isolated from whole-cell preparations by Elson and Chargaff[57]. The inverse patterns of the base compositions of duplex forms of DNA and RNA are again evident in these cells, and this relationship is, in fact, a characteristic feature of the nucleic acids in animal and plant cells.

The asymmetrical RNA of pea seed roots came from the nucleic acid, which remained in the thin transverse segments of the tissue after extraction with *N* perchloric acid at 2–4° over 30 hr.[58]. There is evidence that the degradation of the complementary strand occurs under such conditions[30] and the increased amounts of residual RNA found in the more mature cells[58] are consistent with its template nature.

Genetic Coding in Animal and Plant Cells

The consequences of applying the coding systems of Zubay[54] and Rich[55] to the data for human liver cells are illustrated in Fig. 3. By using the ciphers given in Table 2, the composition of the DNA necessary to operate can be calculated from the asymmetric base-ratios of RNA. Only the first arrangement of the Zubay code is applied, since the others obviously give

Table 3. BASE COMPOSITIONS AND ASYMMETRY FACTORS FOR SINGLE-STRAND AND DUPLEX FORMS OF RNA AND DNA FROM METAZOAN CELLS

Species and tissue	Nucleic acid	Base composition (number per 100 bases): Adenine	Uracil/thymine[a]	Guanine	Cytosine	Asymmetry factor[b]	Ref. No.

[a] Thymine replaces uracil in DNA.

[b] This factor is the sum of the differences between A and U and G and C.

[c] Is isolated from nuclear fraction washed with sucrose-citric acid medium.

[d] Is isolated from combined-particles after histone extraction (see Fig. 1 and text).

[e] Is isolated directly from combined-particles.

[f] Calculated from single-strand RNA as shown in Fig. 1c.

[g] Residual RNA and DNA in tissue after treatment with ice-cold *N* perchloric acid for 30 hr.

(*a*) Base-pair coding (for example, Zubay[44]).

RNA nuclear	DNA base-pairs	Hence in DNA	Per 100 bases	Conclusion
24 –A	G—C (24)	A = 37 + 24	30·5 A	Similar to determined composition of DNA. *Code valid*
15 –U	C—G (15)	T = 24 + 37	30·5 T	
37 –G	A—T (37)	G = 24 + 15	19·5 G	
24 –C	T—A (24)	C = 15 + 24	19·5 C	

(*b*) Single-strand coding (cf. Rich[44]).

RNA nuclear	DNA template	Hence DNA second strand	DNA bases	Per 100 bases	Conclusion
24 –A	T– 24	A– 24	A = 24 + 15	19·5 A	Reverse of determined composition of DNA. *Not valid*
15 –U	A– 15	T– 15	T = 15 + 24	19·5 T	
37 –G	C– 37	G– 37	G = 37 + 24	30 5 G	
24 –C	G– 24	C– 24	C = 24 + 37	30 5 C	

N.B. The same results are obtained with the base composition of RNA isolated from combined-particles after histone extraction

Fig. 3. Procedures for testing coding schemes illustrated with data obtained from human liver cells (*HLM*)

the same result. If the derived composition agrees with the determined one for the RNA, the code may be said to be valid. If it gives the inverse pattern to the actual one, the code is clearly not valid. This unequivocal answer is obtained when the double-strand system of Zubay is compared with the single-strand code of Rich. The DNA base ratios in Fig. 3*a* are very close to the observed values, while in Fig. 3*b* they are clearly the inverse.

As Table 4 shows, such a straightforward distinction cannot always be made when testing the validity of the codes. While there is no doubt that single-strand coding does not apply to animal and plant cells, ambiguity of decision appears when the first two arrangements of the Sinsheimer code are compared with the Zubay system. An arbitrary rating system has been devised to assist in the judgment of their validity (see footnote to Table 4). It indicates a slightly greater identity between derived and determined values for DNA when the Zubay code is applied, since for the rat and pea data the system is *probably* valid, whereas with the Sinsheimer code it is *possibly* valid. However, it cannot be concluded on such grounds that one operates and the other does not. More cogent reasons for rejecting the Sinsheimer code in favour of the Zubay system will be given later.

The vital feature of these tests is that they indicate that the exchange of genetic information between single-strands of DNA and RNA does not occur in these metazoan cells, and that the coding system which operates involves the formation of template single-strand RNA by the genetic activity of the duplex form of DNA.

Genetic Coding in Unicellular Organisms

The DNA and RNA of unicellular organisms have similar base-ratios for their symmetrical forms (Table 5). This is in complete contrast to the inversions characteristic of these nucleic acids in animal and plant cells (cf. Table 3). Where DNA from *Tetrahymena*[59] has adenine plus thymine in excess of guanine plus cytosine, the symmetrical RNA from this protozoan is similarly weighted. Likewise, when guanine and cytosine are high, as in the DNA of *Aerobacter aerogenes*[60], *Escherichia coli*[60] and *Mycobacterium tuberculosis*[61], these bases predominate in the duplex RNA form.

There are sound reasons for regarding base-ratios in Table 5 which have asymmetry factors of 12 and 13 as single-stranded forms of the nucleic acid. The RNA of *Aerobacter aerogenes* was prepared by a series of fractionations in the presence of surface-active agents[62]. All the recent information on the ribosomes from *Escherichia coli* suggests that they contain active template RNA[25,63,64]. In the analysis of the base-ratios of RNA from the 30S, 50S and 70S ribosomes, Spahr and Tissières[65] appear to have isolated the nucleic acid in its template form.

When the different coding systems are tested, as in Table 6, with these base-ratios, it becomes obvious that the method of exchanging genetic information between DNA and RNA in some micro-organisms is entirely different from that operating in animal and plant cells. The systems of Zubay and Sinsheimer (codes *a* and *b*, Table 2) are unmistakably eliminated by the data for unicellular organisms. Instead, the bacterial cells could employ either the duplex systems of Stent and Sinsheimer (codes *c* and *d*, Table 2) or the single-strand information exchange of Rich. The duplex forms of DNA and RNA in *Mycobacterium*

^{d} No values for RNA (single-strand) available.

tuberculosis[61] and *Tetrahymena*[59] show that they probably adopt a similar coding system.

It is found that the compositions of DNA and RNA from a wide range of bacteria confirm in a general way these conclusions. Belozersky and Spirin[60] noted that extremes in DNA composition (cf. Table 5) were accompanied by RNA of more uniform composition. This becomes understandable now that it is apparent that RNA must be isolated in either its single-strand or duplex form in order to reveal its correct base relationship to DNA. The correlation was, however, sufficiently good for the authors to suggest that "part at least of the ribonucleic acid depends on the deoxyribonucleic acid, and that the two nucleic acids may even be similar with respect to their base compositions". Perhaps it can now be said that they are—in their duplex forms.

Nature of Viral Nucleic Acid

Single-strand nucleic acids are known to form the core of two viruses. They are the RNA of tobacco mosaic virus[66,67] and the DNA of the small bacteriophage Φ*X*174, investigated by Sinsheimer[68]. Their asymmetrical base-ratios[68,69] are shown in Table 7 along with the compositions of other viruses and of the RNA or DNA of the host cells. Influenza[70] and poliomyelitis[71] viral RNA's are seen to have similar base asymmetry to 'single-strand' RNA of the chick chorioallantoic cells[72] and *HLM* cells.

A fascinating relationship between the nucleic acids of virus and host cell was revealed when the duplex base-ratios were calculated from single-strand values. With animal, plant and bacterial viruses there was, in each case, a 'cross-over' in the pattern of bases in viral nucleic acid and host RNA or DNA (cf. Table 7). The precision of this inversion is particularly impressive with the viruses of tobacco leaf and *Escherichia coli*. (The similar relationship between polio virus Type I and influenza *LEE* (*B*) strain and host RNA is based on the assumption that these viruses also contain single-strand RNA.)

It may be concluded that, for all the above viruses, the RNA or the DNA represents the 'antithesis' in base composition of the template nucleic acid of the host cells. The 'cross-over' pattern also exists between the duplex DNA in certain viruses (for example, *T*2*r* and *T*7)[73] and the nucleic acids of the infected *Escherichia coli* as seen in Table 7. There is one puzzling exception, quite apart from the problems arising from these observations; the duplex base ratios of bacteriophage *T*3 are unique in having the same base-pattern as the DNA of *Escherichia coli*. It is possible, however, that this aberration can be reconciled, since fraction IV of the bacterial DNA, isolated by column chromatography[74], has a base-pattern which is the inverse of the viral DNA and of the total DNA of the cells (cf. Table 7).

Possible Interpretations

No attempt will be made in this article to explore the genetic consequences of these findings. They cover a wide range of knowledge, and time is needed for reflexion and discussion. For the present, it would seem that the relationships found to exist between DNA, RNA and the histones are more than fortuitous, and they suggest to me a number of concepts which may help to make genetic processes understandable in biochemical terms.

(1) The exchange of genetic information between DNA and RNA is carried out by one coding system in animal and plant somatic cells and by another in some unicellular organisms.

(2) Such ambivalence of code might be provided by the Sinsheimer system, since two of its ciphers could operate in metazoan cells (Table 4) while the other two could operate in micro-organisms (Table 6). It is, therefore, not 'indeterminate', as Sinsheimer intended it to be[68]. There are other conceptual reasons which make its 'universality' improbable. For example, it seems too insignificant a change in

coding to account for the evolution from asexual life to the multicellular and sexual nature of higher organisms.

(3) Zubay devised his coding system to account for inversion of the base ratios for DNA and RNA in animal nuclei. The inversion is confirmed for their symmetrical forms, and it is seen that four stereochemical arrangements of the Zubay system could function in animal and plant cells (Table 4). Zubay[75] has himself provided reasons for rejecting the code, but its observed validity in some metazoan cells leads one to suggest that mating genomes or paired chromatids[76] produce single-strand template RNA within a three-dimensional nucleohistone complex[77,78].

(4) The systems of Stent[52] and Rich[54] are valid for micro-organisms, and the Zubay code is definitely eliminated (Table 6). There are stereochemical grounds for rejecting the use of double-strand DNA templates, proposed by Stent (cf. ref. 55). Thus, single-strand coding between DNA and RNA is more likely to be associated with unicellular organisms and short generation times, whereas, in metazoan cells, double-strand coding by a Zubay cipher is associated with diploid and polyploid cells and longer generation times.

(5) It may be possible, through single-strand coding, to reconcile the co-existence of wide differences in DNA composition in certain micro-organisms (cf. ref. 79) with the known similarity of their protein, as both the DNA strands are theoretically able to act as the genetic templates. There is the interesting contrast that the DNA base ratios of animals and plants are remarkably uniform[11,80].

(6) The presence in ribosomes of histone-like proteins which are latent ribonucleases (and possibly deoxyribonucleases[48]) may provide a mechanism for protecting template RNA while suppressing 'free' RNA of different base composition. In particular, this selective action could prevent complementary polynucleotide from achieving any permanence.

(7) Three distinct histone fractions with ribonuclease activity are found in the nuclei of human and guinea pig cells, while there are only two in the cytoplasmic ribosomes. It seems possible that certain nuclear histones suppress RNA template function and thereby control the differentiation of cells in higher organisms, as originally proposed by Stedman and Stedman[31].

(8) Virus nucleic acids in their duplex forms are usually found to have base compositions which are the 'antithesis' of the corresponding nucleic acids of the host cells. This property may give them immunity to most of the depolymerases of the host cells, while, at the same time, ensuring their replication by association with a particular histone in the host cell. It may be significant that the RNA viruses so far detected only infect animal and plant cells, in which the DNA is always linked to histone, in contrast to the reported absence of the histone moiety in bacterial cells[81,82].

(9) Recently, the discovery that animal viral RNA (Sanders, F. K., personal communication) is first synthesized within the nuclei of the host cells suggests that it may find there 'activating' histones and possibly replicate by single-strand coding through a DNA template as suggested by Rich[54]. Conversely, it is significant that, when DNA bacteriophages infect *Escherichia coli*, an RNA distinct from host cell RNA and similar to phage DNA[83,84] is formed before any DNA of the progeny can be detected.

The contributions of R. Hayward, J. J. Childs, S. J. Martin and Miss D. M. McMaster in these investigations are greatly appreciated. The technical help of J. Monaghan and P. McParland has been most valuable. In the preparation of this manuscript, helpful discussions with Prof. D. C. Harrison, Mr. R. Hayward, Mr. S. J. Martin, Dr. J. Paul and Prof. G. Pontecorvo are gladly acknowledged.

The work has been supported by grants from the Medical Research Council, the British Empire Cancer Campaign and the Empire Rheumatism Council.

Note added in proof. Yčas and Vincent[85] have compared the specific activities of the 2′,3′ and 5′ forms of nucleotides obtained from RNA extracted from yeast cells with boiling 2 *M* sodium chloride. The pattern of asymmetry of labelling with phosphorus-32 in both forms of nucleotides is in general similar to the pattern observed in the 2′,3′-nucleotides from nuclear and ribosomal RNA of *HLM* cells at short labelling times. Analysis of their results leads the authors to conclude that there is, in their material, a small fraction of RNA with a high rate of turnover which is closely similar in base composition to that of yeast DNA. Their suggestion that this RNA might be a primary gene product is compatible with its formation by the Rich[55] or Stent[52] coding systems for RNA template formation.

A TRANSATLANTIC COMMUNICATION EXPERIMENT VIA *ECHO* I SATELLITE

By H. CARRU, R. GENDRIN and M. REYSSAT

Centre National d'Etudes des Télécommunications, Département Communications et Détection Spatiales, Issy-les-Moulineaux (Seine)

THE *Echo* I satellite, launched on August 12, 1960, by the National Aeronautics and Space Administration of the United States, was originally a sphere 100 ft. in diameter, coated with vapour-deposited aluminium to provide radio wave reflectivity of 98 per cent up to frequencies of 4,000 Mc./s. The purposes of the experiment were, first, to check various systems of modulation for 'passive' communications, and, second, to investigate scintillations (which arise in the actual process of reflexion from the satellite), Faraday rotation, fading and polarization

The experiment that we describe here involved communication using continuous wave transmissions only; it was performed on August 18 between Holmdel (New Jersey) and Issy-les-Moulineaux (France). A few days later a modulated signal was received at Jodrell Bank (Great Britain) with the big antenna.

A description of the equipment used by us is given elsewhere[1,2]. We shall give only the numerical characteristics of each component. The parabolic antenna (3·3 m. diameter) is not steerable automatic-

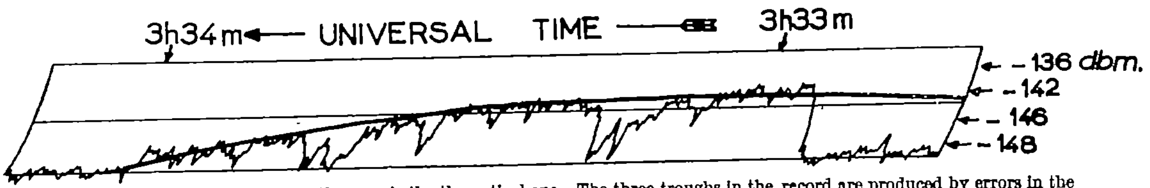

Fig. 1. Amplitude. The smooth curve is the theoretical one. The three troughs in the record are produced by errors in the frequency tracking

ally, so it was pointed to some definite direction before each pass. A flexible air-dielectric cable (100 ft. in length, 1·6 db. loss) was used to join the antenna to the parametric amplifier. The latter was operating in the degenerate mode, and gave an over-all receiver noise figure (measured with respect to 290° K.) less than 5 db. After mixing, the signal is fed to a phase-lock receiver[2,3] which reduces the effective band-width to about 20 c./s., but nevertheless is able to track variations of frequency produced by the Doppler effect. The threshold of the lock-in system is 7 db. above noise-level.

It is now easy to compute the power at amplifier input corresponding to the weakest signal which can be recorded. We have:

kTB =	– 161 dbm.
Noise figure	5 db.
Threshold	7 db.
Total $P_{\text{min.}}$ =	– 149 dbm.

This was in fact the figure measured with a calibrated signal generator (see Fig. 1).

Now we must compute the expected power P available at the focus of the antenna. This power is given by the following equation:

$$P = \frac{P_E G_E D_S^2}{16 l_1^2} \cdot \frac{\eta A}{4\pi l_2^2} \qquad (1)$$

in which P_E, transmitter power, is 9×10^3 W.; G_E, gain of the transmitting antenna (estimated), is 44 db.; l_1, distance between satellite and transmitter, is 4,000 km.; l_2, distance between satellite and receiver, is 3,300 km.; D_S, satellite diameter, is 30·5 m.; A, area of receiving antenna, is 8·55 m.^{2}; η, receiving antenna efficiency, is 0·47. With these data, equation (1) gives:

$$P = -136 \text{ dbm.}$$

However, three additional facts must be taken into account. First, the transmitted polarization was circular, whereas our primary feed was linearly polarized, thus losing 3 db. Secondly, the transmitter – satellite – receiver angle was 81°, which is very near the value 90° for which the scattering coefficient is reduced by 1·3 db. compared with the isotropic case[4] (for which we have assumed a cross-section of $\pi D_S^2/4$ rather than πD_S^2 as is assumed in ref. 4). Finally, we have to subtract the 1·6 db. loss of the cable.

Thus the maximum available power at the amplifier input is:

$$P_{\text{max.}} = -142 \text{ dbm.}$$

The difference between $P_{\text{max.}}$ and $P_{\text{min.}}$ is only 7 db., and, due to the great number of variables on which it depends, this very narrow margin can explain why, among the twelve trials that we made, only one was completely successful.

Results

In this particular trial, the antenna axis had an elevation of 15° ± 1° and an azimuth of 277° ± 1° (north to east). The signal was received for 1 min., from 3h. 32m. 56s. to 3h. 33m. 56s. U.T. This duration was about half what was hoped for, the discrepancy being due to instrumental difficulties. Because of the difference between the actual frequency of the transmitter (≃ 960·045 Mc./s.) and the value originally announced (960·050 Mc./s.), we wasted time looking for the signal around a false frequency.

The amplitude recording is given in Fig. 1. Noise is superposed above the monotonically decreasing signal. The lock-in system fell out of lock three times, and this fact explains the three troughs in the record.

Simultaneously, the frequency was printed every 2 sec.; Fig. 2 gives the plotted results. The stability of our frequency standard was better than 1 part in 10^8 a day.

Comparisons

(a) *Orbital parameters.* In order to make some comparison with the theoretical prediction, we have computed the position, distance, and Doppler effect from 3h. 30m. to 3h. 35m. We assumed a Keplerian orbit, with both the right ascension of the ascending node and the argument of the perigee varying linearly with time. Orbital parameters were taken from the *Space Track Bulletins*, the accuracy of which was very poor in the early part of the life of *Echo* I. (For example, the time of nodal crossing for revolution No. 70, given in *Bulletin* 3, was 3h. 00m. 55s.;

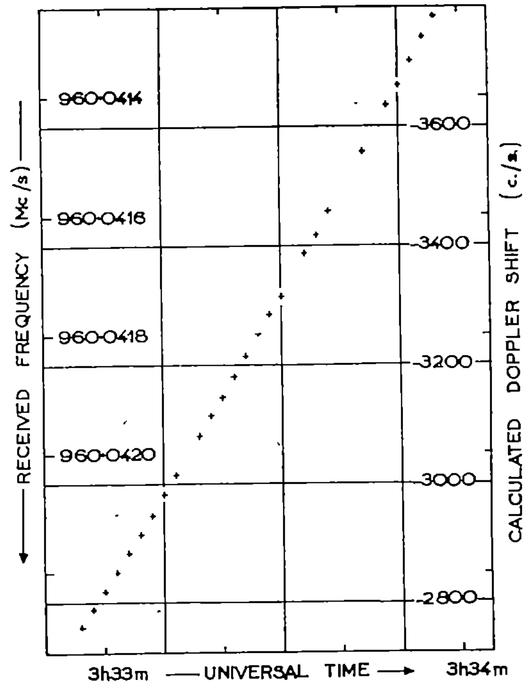

Fig. 2. Frequency. Only the measured points are shown: for comparison with the theoretical curve, see Fig. 3

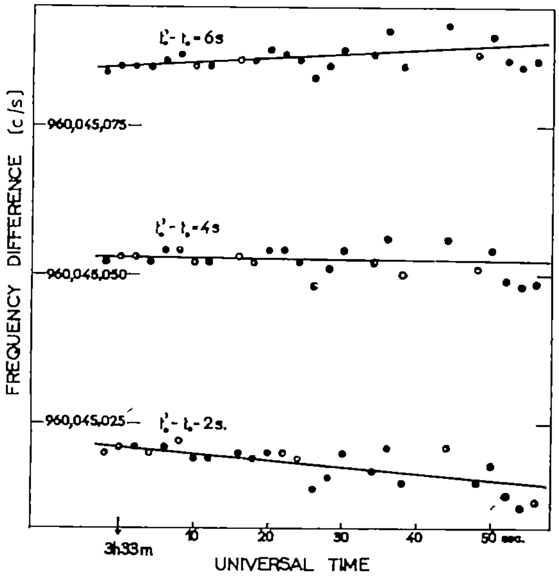

Fig. 3. Difference between the received frequency and the calculated Doppler shift, for three possible values of the time of nodal crossing. This difference is equal to the frequency of the transmitter. If this one had good stability, we must choose $t_0 = t'_0 - 4$s., and therefore $f_0 = 960\ 045053$ Mc./s.

the same time, computed by extrapolation from *Bulletin* 4, was $t'_0 = 3$h. 00m. 31s., and the actual time was $t_0 = 3$h. 00m. 27s. ± 2s., as will be seen below.) We used for our computations the value t'_0, and corrected it, after the event, so as to obtain the best fit between the experimental and theoretical curves; this parameter is the most important one, since, for a duration of 5 min., the others give only a correction of a higher order.

The correction was made by two independent methods. The first method consists in comparing the computed Doppler curve with the observed one, and in seeking the time-shift that gives the best fit between them. Fig. 3 shows the difference between observed frequency and calculated Doppler shift for three possible values of $t'_0 - t_0$, namely, 2s., 4s. and 6s. We see that the values of 2s. and 6s. both imply a considerable drift of the transmitter frequency, of the order of 4 c./s./min. If, as we suppose, the transmitter frequency had in fact good stability (better than 10^{-8} a day), we must choose $t'_0 - t_0 = 4$s.

The second method consists in computing azimuth and elevation for the revolutions $n = 55, 56, 57, 80, 81, 82$, and in comparing them with the optical data (kindly communicated by Prof. P. Muller) for these revolutions; cloudy weather prevented Prof. Muller from observing on the particular night of our experiment.

For each revolution the curves fit well (within ± ½°) provided we suppose that there is a difference between the chosen time t'_n and the actual one (t_n). The differences $t'_n - t_n$ are plotted with respect to n in Fig. 4. A parabola drawn through the six points on this plot gives also $t'_0 - t_0 = 4$s. A parabola is involved because not only was an erroneous value chosen for the nodal period, but also this period was assumed to remain constant, whereas in fact it decreased with increasing time.

(*b*) ***Frequency curve.*** From the best fit of the two Doppler curves, we are able to compute the transmitted frequency:

$$f_0 = 960\ 045\ 053 \text{ c./s.}$$

The error Δf_0 in our measurement of f_0 can be calculated by assuming a maximum error $\Delta t_0 = \pm 2$ sec. in the time of nodal crossing. The slope of the frequency curve being about 1,050 c./s./min., the resulting Δf_0 is ± 35 c./s. as we can also see on Fig. 3, to which we must add the error of our frequency standard, so that:

$$|\Delta f_0| \leqslant 45 \text{ c./s.}$$

Examination of the points on Fig. 3 shows that their scatter is less than ± 4 c./s., and increases when the signal strength decreases (see also Fig. 1); this is a property of the phase-lock system. When compared with the scatter generally obtained in measurements of the frequency of satellite-borne oscillators[1], the present superiority of ground-located transmitters is obvious.

(*c*) *Amplitude recording.* Now, we will turn our attention to the amplitude recording. First the maximum strength of the received signals is − 142 dbm., that is, it is very close to the predicted strength (within ± 1 db., which was the limit of accuracy of the calibration). Thus the reflexion seems to occur as in the idealized case; this implies a good sphericity of the balloon and no significant deterioration of the coating.

Secondly, the decreasing strength of the signal is fully explained by the passage of *Echo* I through the reception pattern of the antenna, thus excluding large fading of period less than ≃ 1 min. This can be shown by computing azimuth and elevation and drawing the path as the satellite crosses the antenna pattern (Fig. 5). From this curve, we can deduce, with respect to time, the theoretical strength of the signal, and compare it with the experimental one; we do not make any allowance for the variation of l_1 and l_2, since their squared product has a negligible variation during 1 min. (< 0·2 db.). The best fit (smooth curve of Fig. 1) is obtained when we suppose not only that $t_0 = t'_0 - 4$s., but also that our antenna beam was pointed towards *B* (Fig. 5) rather than towards *A*. This remains well within the accuracy of ± 1°. (A change from *A* to *C* would not affect very much the shape of the curve.)

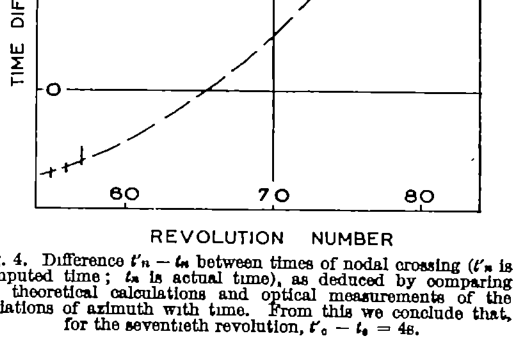

Fig. 4. Difference $t'_n - t_n$ between times of nodal crossing (t'_n is computed time; t_n is actual time), as deduced by comparing the theoretical calculations and optical measurements of the variations of azimuth with time. From this we conclude that, for the seventieth revolution, $t'_0 - t_0 = 4$s.

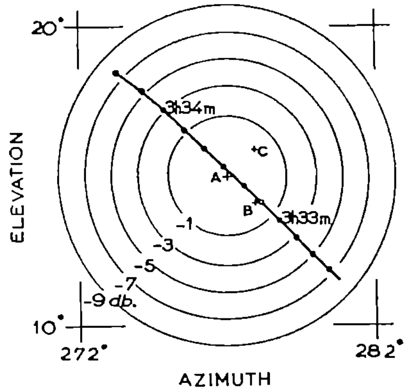

Fig. 5. Crossing of the antenna beam by *Echo* I (points every 10 sec.). *A* is the theoretical beam axis, *B* is the beam axis giving the best agreement with the experimental amplitude record. (The great circles are to be shifted in the same manner)

Fig. 5 also shows that, if we had had a receiving antenna with a beam width of 1° (as for the transmitting antenna at Holmdel), an error of tracking of ½° in angle, or of 5s. in time, would have given a loss of 3 db. (Losses of 5 db., because of lack of tracking accuracy, were found by another observer[5].)

Conclusion

This experiment, among many others, has proved the success of the *Echo* I project; in particular, it showed that the reflectivity of the coating is good, and that the received signals are free from rapid fading.

We have also seen the necessity of a big steerable antenna, in order not only to have better gain (say, 10 db. more), but also to avail oneself of the low temperature of the sky. But the beam-width of the antenna must not be too small, unless very good means of tracking are available.

From the point of view of communications, we must pay attention to the very unfavourable power balance in the use of a passive satellite; even with elaborate equipments, the band-width capabilities are limited to a few voice channels. But the simplicity of the balloon, together with the value of the many scientific results obtained with *Echo* I, argue for more elaborate tests of this kind.

Thanks are expressed to the National Aeronautics and Space Administration, which gave us much information, and to the Bell Telephone Laboratories, which supplied the transmissions to the balloon at the time when it was visible from both Europe and America.

We are indebted to Prof. P. Muller of Meudon Observatory for his optical observations, to Mrs. Epfelbaum for her constant help in the computations, and to the Direction des Etudes et Fabrications d'Armements for the loan of an electronic computer.

OBITUARIES

Prof. J. S. Rankin

Dr. James S. Rankin, Freeland professor of natural philosophy in the Royal College of Science and Technology, Glasgow, died on November 16 in his sixty-seventh year.

Dr. Rankin joined the staff of the Natural Philosophy Department of the College in 1919, after a few years of postgraduate experience in industry, and except for the period 1943–45, when he was seconded to the University of Istanbul to occupy the chair of theoretical mechanics, his service to the College remained unbroken. He was appointed to the Freeland chair in 1942, and under his leadership the Department was a most stimulating place in which to work. His research interests extended over a wide field, his most notable work being concerned with the phenomenon of magnetostriction and, in particular, with attempting to explain the changes in the magnetostriction of steel resulting from various degrees of tensile over-strain.

One of his greatest achievements lay in the development of his course leading to the associateship of the College in applied physics. None of his predecessors had thought of the Department as other than an ancillary one for the engineering and other applied science courses in the College. In 1947 he set about his task of building up a school of applied physics which would have a recognized place in the higher aspects of technology. It was characteristic of his vision and determination that he succeeded, and young graduates from his school are now helping to bridge the gap that exists in industry between the 'pure' physicist and the engineer.

Among his other activities he was a governor of the West of Scotland Agricultural College, a member of the Vice-Chancellors' Committee on Hungarian Students and an ex-chairman of the Scottish Branch of the Institute of Physics and the Physical Society.

He had great gifts which he put to fine use in the service of the College. A devoted teacher, he will long be remembered by generations of students who came to know the warmth of his friendship.

J. W. Sharpe

Mr. E. C. Fieller

Edgar Charles Fieller, officer-in-charge of the Statistical Advisory Unit of the War Office, died suddenly on December 1. He was fifty-three years of age.

A prominent member of the Royal Statistical Society, he had served as a vice-president, several terms as a member of Council, as secretary, then chairman of the Research Section, and as a member of several committees. In 1960 the Society honoured him by the award of the Guy Medal in silver. He was for four years secretary of the British Region of the Biometric Society.

As a young man, after taking the Mathematical Tripos as a scholar of King's College, Cambridge, he was for a time a member of Prof. Karl Pearson's staff. This began an association with the School of Statistics at University College, London, which was renewed in later years through his membership of the University board of studies and by his appointment as an examiner.

His subsequent experience with Messrs. Boots led him into the fields of market research and bioassay, in which he made several original contributions; one of these, a method for obtaining confidence limits for a ratio, is now well known as Fieller's Theorem.

Fieller served during the Second World War in the Operational Research Group of Fighter Command, R.A.F., part of the time as deputy to the officer-in-charge. After the War he joined the National Physical Laboratory in charge of the Statistics Group of the newly formed Mathematics Division. This Group was eventually transferred to the Ministry of Supply and, on the dissolution of that Ministry, to the War Office.

While on leave of absence from the Ministry of Supply, he fulfilled an assignment in Turkey for the Food and Agriculture Organization of the United Nations. There he conducted a training course in sampling methods which enabled a national survey to be made. He made many friends in Turkey, and his work there will have lasting effect.

In later years, when Fieller became a member of the International Statistical Institute, he made a particular point of seeking the acquaintance of the mathematical statisticians of other countries. These personal friendships must have made a considerable contribution to international understanding.

Fieller's published work of earlier years on probability problems and on bioassay was supplemented later by a paper on fiducial limits; in this, with his usual caution, he pointed out the consequences and paradoxes of a theory while reserving judgment on controversial points.

The pleasure he took in social contacts, his understanding of others and his fund of anecdotes, made him a good companion who will be missed in many places.

E. D. VAN REST

NEWS and VIEWS

Entomology at the British Museum (Natural History): Dr. W. E. China, C.B.E.

DR. W. E. CHINA, who retires from his post as keeper of the Department of Entomology in the British Museum (Natural History) at the end of January, is a world authority on the insect order Hemiptera. During his thirty-nine years of service on the staff of the Department he has published more than two hundred papers on the structure, taxonomy, evolution and zoo-geographical distribution of this group of insects. After his retirement he intends to return to this work, which his administrative duties as keeper have interrupted. He became deputy keeper in 1945 and was largely responsible, under the keeper, Mr. N. D. Riley, for the rehabilitation of the Department of Entomology after the war-time bombing and the return of the National collection of insects, much of which had been evacuated. On the completion of the new building in 1951 he was concerned with the keeper in organizing the re-allocation of the entire entomological collection. He was appointed keeper in 1955. Dr. China is a foreign member of the Societas pro Fauna et Flora Fennica and corresponding member of the Société Entomologique d'Egypte. In 1959, he was appointed assistant secretary of the International Commission on Zoological Nomenclature.

Engine Research, Ministry of Aviation: Mr. Peter Lloyd, C.B.E.

MR. PETER LLOYD has been appointed director general engine research and development, Ministry of Aviation, in succession to Mr. R. H. Weir, who is now director of the National Gas Turbine Establishment, Pyestock. Born in 1907, Mr. Lloyd went from Greshams School, Holt, to Trinity College, Cambridge, in 1925, where he took the Natural Science Tripos, Parts 1 and 2 (chemistry). After a year's research under Dr. (now Sir) Eric Rideal and a year in the German chemical industry, he was with the Gas Light and Coke Co. from 1931 until 1940 in charge of research on the industrial utilization of gas. In 1940 he joined the Royal Aircraft Establishment working first for Prof. G. T. R. Hill in the Air Defence Department at Exeter, and then in 1941 under Hayne Constant and W. R. Hawthorne in the turbine division of the Engine Department. With that team he transferred to Power Jets, Research and Development, Ltd., at Pyestock, in 1944, and soon after that body became the National Gas Turbine Establishment he became a deputy director. During the first part of this period his work was mainly concerned with combustion researches including studies of spontaneous ignition characteristics at high temperatures and the evaporation and burning characteristics of liquid fuel drops in high-speed air streams. Latterly he assumed a more general responsibility for Pyestock's research on aerodynamic, mechanical and metallurgical problems. Following two visits to Australia in connexion with the work of the Commonwealth Advisory Aeronautical Research Council, he was posted to Australia in 1960 as temporary head of the Ministry of Aviation Staff, during the period of recent negotiation with the Australian Government on space research. Peter Lloyd is a mountaineer who has taken part in three Himalayan expeditions, including the 1938 attempt on Everest, in the course of which he made the first comparative trial between open- and closed-circuit equipments. As a member of the Himalayan Joint Committee of the Alpine Club and the Royal Geographical Society he was closely concerned with the assaults on Everest, being responsible for the provision of the oxygen equipment used in the successful assault.

Monsanto Chemicals, Ltd.: Senior Scientist

DR. I. S. WILSON has been appointed senior scientist to Monsanto Chemicals, Ltd. This appointment is part of a Monsanto scheme under which outstanding scientists on the company's staff may receive proper recognition of their status while continuing to specialize in scientific or technical work rather than accepting increased administrative responsibility. In his new capacity Dr. Wilson will be free to devote his whole time to research on effluent treatment and the microbiological breakdown of organic compounds.

The Leopoldina German Academy of Sciences : Elections

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members, in the sections indicated : *Mathematics*, Prof. Emil Artin (Hamburg) ; Prof. I. R. Safarevic (Moscow) ; Prof. B. L. van der Waerden (Zurich). *Pathology and Anatomy*, Prof. Gunter Bruns (Halle) ; Prof. Hermann Chiari (Vienna) ; Prof. Wilhelm E. Ehrich (Philadelphia) ; Prof. Andreas Werthemann (Basle). *General Biology*, Prof. Th. Dobzhansky (New York) ; Prof. Ake Gustafsson (Stockholm) ; Prof. Herman J. Muller (Bloomington) ; Prof. I. I. Schmalhausen (Moscow) ; Prof. Josef Straub (Cologne). *Zoology*, Prof. Robert Mertens (Frankfurt on Main).

Indian Institute of Science : Golden Jubilee

ON glancing through the Golden Jubilee Research Volume of the Indian Institute of Science (Bangalore, India, 1959), one is agreeably impressed by the diversity and range of scientific endeavour in India. As one would expect in a country developing its technology, applied science is given certain emphasis. There are articles on mineral flotation and extraction, turbomachines, silkworm nutrition, alloys, electronics research, soil fungi and concrete curing. But in more fundamental areas, too, research has been contributed —organic chemical syntheses, chemical kinetic investigations, derivation of expressions for compressible fluid-flow in the presence of magnetic fields, Hermite orthogonal functions and so forth. Science in India appears to have a character of its own—somewhat refreshing in this world of fading individuality. One article, for example, describes research on an Ayurvedic medicinal preparation called 'drakshasava'. This fermentation product has been of wide popularity in the country for a long time. It is claimed to cure a range of maladies like indigestion, cholic, insomnia, loss of appetite, phthisis and 'excessive debility'. An elegant microbiological evaluation of the drug was carried out. It was found only to support the growth of the micro-organism, *Saccharomyces cerevisiae*. Also, addition of vitamins and amino-acids did not stimulate growth. Except for sugars and trace elements, the drug did not contain essential growth factors—its only tonic effect appeared to be due to its alcoholic content. Pharmacological examination would be required to reveal the presence of very small quantities of ingredients which do cause the healing properties claimed. Nevertheless, establishing the use of microbiological technique in this way does provide scope for probing into these age-old medicines and disclosing their mysteries.

Mathematics in South Asia

THE report of the Second Conference on Mathematical Education in South Asia, held at Bombay in January 1960, has now been issued (Pp. xxiii+205 ; Tata Institute of Fundamental Research, Bombay ; September 1960). Prof. Chandrasekharan, of the Tata Institute, presided over the Conference, and in his presidential address he urged the Conference not to think entirely of technical problems but to remember also that the great need in South Asia is the construction of a social and educational environment conducive to the growth of creative scholarship. In the report, the invited addresses are published in full, and the proceedings of the working parties are summarized. The accounts of the progress of mathematical education in Malaya, Indonesia, Thailand, Pakistan and Ceylon show what efforts have been made to implement the suggestions put forward by the first Conference (February 1959).

While emphasizing the vastness and complexity of the task, the addresses are optimistic, confident that in a short time significant progress towards national mathematical education culminating in vigorous schools of research will have been made. The other invited addresses, by mathematicians from Europe, North America and Asia, deal mainly with algebra and geometry, in the upper school, at the undergraduate-level, and in the first postgraduate year. Generally, stress is laid on the axiomatic approach and the basic importance of modern linear algebra, founded on a school knowledge of the elements of vector algebra and of sets of linear equations. Several of the addresses advocate an earlier introduction, in the universities, of modern abstract and general methods, on the grounds that students of to-day are not afraid of abstractions and can thus derive full advantage from an early acquaintance with general methods. The reports of the working groups preserve the flavour of lively and provocative discussions.

The Manchester Literary and Philosophical Society

VOLUME 102, 1959–60, of the Memoirs and Proceedings of the Manchester Literary and Philosophical Society well justifies Sir Cyril Hinshelwood's commendation of the Society in opening its new buildings in September (Pp. 81 + xliii. (Manchester : Manchester Literary and Philosophical Society, 1960.) 31*s*. 6*d*.). It includes the presidential address of Mr. C. E. Young on the growing importance of organo-metallic chemistry ; Dr. G. E. R. Deacon's Clayton Memorial Lecture on the scientific exploration of the oceans ; Prof. R. D. Waller's lecture on Danilo Dolci and his sociological work in Sicily and southern Italy ; Sir Gordon Sutherland's lecture giving some comparisons of British and American Universities ; and Prof. C. F. Carter's assessment of the practical value of the economist in government and in business in which he suggests that the Minister for Science should encourage a joint technical and economic appraisal of the opportunities for State-encouraged scientific development.

Irregularities in Spelling

BACKWARDNESS in the basic subjects has been the subject of considerable unfavourable comment by industrialists and others since the War. Among the causes of backwardness in reading, English spelling has long figured as an important factor. Spelling reform has been increasingly mooted since George Bernard Shaw's bequest for this purpose, and recently, the National Foundation for Educational Research in England and Wales in conjunction with the University of London Institute of Education agreed to undertake research into the alphabet form. An important preparatory step has been Dr. W. R. Lee's scientific study of the part played by spelling irregularity as a contributory cause of backwardness in reading. The results of his investigations have now been published under the title "Spelling Irregularity and Reading Difficulty in English" (Occasional Publication, No. 2 : Pp. i+74. London : National Foundation for Educational Research in England and Wales, 1960. 10*s*.). It has been maintained that, if each sound were always represented by the same letter, reading proficiency and reading habits would be achieved more easily. This study examines this hypothesis against experience at home and abroad, and follows this up with objective testing in experimental situations. The decisive conclusions should form an invaluable aid to teachers, administrators and all concerned with progress in education.

Foot-and-Mouth Disease in Madras

IN the combined report of the King Institute of Preventive Medicine, Guindy, and the Government Analyst, Madras, for the year 1957–58, information is provided about the problem of foot-and-mouth disease in Madras State (Report of the King Institute of Preventive Medicine, Guindy, and Report of the Government Analyst, Madras, for the period from 1st April, 1957, to 31st March, 1958. Pp. i+121. Guindy, Madras: King Institute of Preventive Medicine, 1960). The conclusions of a committee set up to examine the position were that: foot-and-mouth disease is endemic in the whole Madras State and occurs year after year; the carrier state of the infected animals is quite long and lasts a year; it is not practicable to select virus-free animals for vaccination; and that with the facilities available at the Institute, every possible precaution has been taken to minimize the infection and its spread. The committee was of the opinion that controlled measures have become all the more important, as prophylactic vaccines against foot-and-mouth disease are not available in India. It is also not practicable to import vaccines from abroad as they are very costly and protection against local strains cannot be assured. The report contains detailed information about all measures taken to safeguard public health in the State.

A New Frog from Brazil

AMONG the specimens in a small collection of frogs sent to Coleman J. Goin of the University of Florida was a single individual of a striking little *Hyla*. It has been named *Hyla bokermanni*, n. sp. The specimen was an adult female and has small rounded vomerine tooth patches and small rounded dorsolateral stripes on a chocolate-brown background. It is perhaps most closely allied to *H. parviceps*, from which it differs in its smaller size, shorter legs, smoother skin, and in having a pattern of dorsolateral stripes as well as differences in detail of pattern of the thighs. From *H. microps*, which may also be a near relative, it likewise differs in its small size, shorter legs and in the pattern of dorsolateral stripes (*Ann. Mag. Nat. Hist.*, 2, No. 24; December 1959).

Fecundity of the Nile Mormyrid, *Hyperopisus bebe* (Lacepede)

ATTENTION has recently been directed to the importance of the fish fauna of the Nile as a valuable source of protein food. Experimental stations have been constructed for the breeding of some of the economically important species of the Nile fishes. Work on the fecundity of the Nile fishes would, therefore, be of importance for such projects and for a general control scheme for the maintenance and increase of the productivity of the rivers, but except for the observations made by Kenchington in 1933 on the fecundity of the Nile perch *Lates niloticus* (Linnæus 1762) no one has previously examined this problem. G. Nawar has now investigated the fecundity of *Hyperopisus bebe* (Lacepede) (*Ann. Mag. Nat. Hist.*, 2, No. 22; October 1959). The fecundity, defined as the number of eggs produced by the female during the breeding season, was determined through the study of 62 females. It was found to vary in the range 2,030–33,060, provided that the fecundity is calculated on the basis of counting the whole number of ova per ovary. A correlation between fecundity, length and weight of the specimen was observed.

New Virus Isolated from Culicine Mosquitoes

DURING April 1958, an outbreak of febrile illness of unknown ætiology occurred among the residents of Germiston, a town near Johannesburg. As it was considered that this outbreak might have been due to an arthropod-borne virus, mosquitoes were collected with the intention of isolating the causal agent. In the centre of Germiston, which is a highly industrialized town, is a small lake with an adjoining golf course and park. On the edge of the lake is a dense reed-bed with a heronry in which large numbers of cattle egrets (*Bubulcus ibis*) roost and breed. At the time the mosquito collections were made, the heronry contained hundreds of fledgling cattle egrets. Associated with the reeds and surrounding trees were lesser numbers of black-headed herons, sacred ibises, coots, moorhens, reed warblers, weavers and doves. Mosquitoes were collected on the edge of the lake in proximity to the reeds. From *Culex* (*Neoculex*) *rubinotus* Theobald mosquitoes collected at Germiston, three virus strains were isolated. Two of these strains were identical and have been shown to belong to the Bunyamwera group of arthropod-borne viruses. B. M. McIntosh, R. H. Kokernot and H. E. Paterson report in the April issue of the *South African Journal of Medical Science* that they have now isolated a third virus strain which has been shown to be unrelated immunologically to many arthropod-borne viruses. Accordingly, the name Witwatersrand virus has been proposed, which has reference to the geographical area where the mosquitoes were collected and from which the agent was isolated.

Essay Competition on Corrosion Science

THE Corrosion Group of the Society of Chemical Industry is organizing a competition designed to encourage persons who are still in the early stages of their career to take an interest in corrosion science. The competition will take the form of an essay, and persons aged not more than 30 years are invited to present an essay or paper on any aspect of corrosion of metals and its prevention. A prize of 25 guineas will be awarded. The closing date for receipt of entries is March 31, which should be addressed to Corrosion Group Essay Competition, c/o Society of Chemical Industry, 14 Belgrave Square, London, S.W.1, whence further information can be obtained.

"Effect of Corona Discharges on Polyethylene"

REFERRING to the communication under this title published in *Nature* of November 12, 1960, p. 577, Mr. L. R. Hougen states: "Further work has revealed that the identification of the alcohols in the gas chromatogram (Fig. 1) is incorrect, due to false labelling of the marker compounds, which was beyond my control. A correct interpretation of the gas chromatogram indicates that the distribution of breakdown products between the different carbon numbers is statistical, and that the largest peak represents C_{20} secondary alcohols, which suggest that a free-radical mechanism may play an active part in the breakdown reactions".

The Night Sky in February

New moon occurs on Feb. 15d. 08h. 11m. u.t.; full moon does not occur this month. The following conjunctions with the Moon take place: Feb. 2d. 07h., Regulus 1° N.; Feb. 13d. 06h., Jupiter 4° S.; Feb. 13d. 07h., Saturn 3° S.; Feb. 18d. 11h., Venus 7° N.; Feb. 22d. 20h., Aldebaran 0·2° S.; Feb. 24d. 17h., Mars 8° N. Jupiter is in conjunction with Saturn on Feb. 18d. 15h., Jupiter 0·2° S.; this phenomenon occurs once every twenty years, and on this occasion the approach is unusually close, but conditions for observation are unfortunately not favourable. There is a total eclipse of the Sun on February 15, visible as a partial eclipse at Greenwich. The eclipse will be total along a track passing through southern France, northern Italy, the Balkans and parts of the U.S.S.R., where there will be a maximum duration of 2m. 45s. Seen from Greenwich, the partial eclipse begins before sunrise, attains its maximum phase of 0·93 at 7h. 42m., and ends at 8h. 47m. This is the largest eclipse to be seen from Greenwich since 1927 and until 1999. Mercury will be visible as an evening star during the first half of the month. Venus is an evening star, favourably placed for observation. Venus sets at 21h. 20m., 21h. 45m. and 21h. 50m. on February 1, 15 and 28, respectively, more than 4 hr. after the Sun. During the month its distance from the Earth decreases from 63 to 44 million miles, the visible portion of the apparent disk from 0·499 to 0·315, and its stellar magnitude from −4·1 to −4·3. Mars sets at 6h. 00m., 5h. 10m. and 4h. 25m. at the beginning, middle and end of the month, respectively. Mars is very conveniently situated for observation. It is at a distance of 80 million miles from the Earth on February 15, and its stellar magnitude is −0·1. Jupiter and Saturn are too close to the Sun for easy observation; they are only observable in the twilight before sunrise. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Feb. 10d. 5h. 19·7m., 24 Sco. (*R*); Feb. 22d. 21h. 18·8m., 89 Tau. (*D*); Feb. 23d. 18h. 01·6m., 111 Tau. (*D*); Feb. 26d. 22h. 19·1m., 5 Cnc. (*D*). *D* and *R* refer to disappearance and reappearance, respectively.

Announcements

Dr. Rudolf L. Mössbauer has been awarded the 1960 Research Corporation Award by the California Institute of Technology and Research Corporation for his work on the production and detection of gamma rays. Dr. Mössbauer is at present on leave of absence at the California Institute of Technology from the Institute of Technical Physics, Munich.

Among the recent changes in administration and organization of the Akers Research Laboratory, Imperial Chemical Industries, the following appointments are announced: Dr. P. W. Brian, to become associate research manager of the Pharmaceutical Division and to be in general charge of the Laboratory; Dr. J. Chatt, to become group manager of the Heavy Organic Chemicals Division. Dr. Chatt will continue in charge of the Organic Chemistry Department.

The Automatic Programming Information Centre, Brighton Technical College, is organizing a course in Algol 60 during April 5–6. Further information can be obtained from Richard Goodman, Automatic Programming Information Centre, Brighton Technical College.

The annual general meeting of the Scottish Branch of Aslib is to be held at the National Engineering Laboratory, East Kilbride, on February 3. Further information can be obtained from the honorary treasurer, J. R. K. Pirie, M.E.R.L. (Aslib), East Kilbride, Glasgow.

The Institute of Physics and the Physical Society is organizing a conference on "The Crystal Structures of Organic Compounds" in the Chemistry Department of the University of Glasgow during April 6–7. Further information can be obtained from the Secretary of the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

The Faraday Society is organizing an informal discussion on "Mechanisms of the Gas-Phase Reactions of the Halogens and their Compounds" at the Chemistry Department, University College, Cardiff, on March 28. The programme will be divided into two sections: (*a*) Oxidation processes; (*b*) reactions of elementary halogens. Further information can be obtained from Dr. J. H. Thomas, Chemistry Department, University College, Cathays Park, Cardiff.

A conference is being organized by Research and Control Instruments, Ltd., on "X-ray Analytical Methods" at the Department of Geology, University of Manchester, during March 20–24. Further information can be obtained from the Conference Secretary, Research and Control Instruments, Ltd., Instrument House, 207 King's Cross Road, London, W.C.1.

The Institution of Mechanical Engineers is organizing a symposium on "User Experience of Large-Scale Industrial Vacuum Plant" at the Institution during March 1–2. The symposium is being sponsored by the Joint British Committee for Vacuum Science and Technology. Further information can be obtained from the Secretary of the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

The Department of Scientific and Industrial Research is organizing a two-day national conference on "Science and Industry—the Problem of Communication", which is to be held at the Brangwyn Hall, Swansea, during April 18–19. Further information can be obtained from the Press Officer, Central Office of Information, Park Place, Cardiff, or the Department of Scientific and Industrial Research Press Office, 5–11 Regent Street, London, S.W.1.

An all-day meeting of the Welsh Soils Discussion Group will be held in the Department of Agricultural Chemistry, University College of North Wales, Deiniol Road, Bangor, on February 8, to consider "Glaciation in Wales as related to Soil Profile Development". Further information can be obtained from D. F. Ball, The Nature Conservancy, Penrhos Road, Bangor, Caernarvonshire, or James A. Taylor, Department of Geography, University College of Wales, Alexandra Road, Aberystwyth.

Erratum. We regret that the title of the communication by J. S. Machin and D. L. Deadmore in *Nature* of January 21, p. 223, is incorrect; it should read, "Thermal Stability of $TiOF_2$". Throughout the text the formula '$TiOF_2$' should be substituted for 'titanium dioxide', except where the latter is defined as anatase and in the third paragraph from the end.

THE NUFFIELD UNIT OF TROPICAL ANIMAL ECOLOGY

IN the past few years biologists in general have come to realize the great importance of an intensive study of tropical animals, their ecology, and the conditions of their existence. It is not merely that tropical Nature is a source of invaluable scientific information which is in danger of vanishing through the changing of the face of the Earth by man. It is also that the fauna of tropical nature reserves gives us an opportunity of determining with precision the factors that control both the physiology of individual animals and the size of their populations under conditions as yet relatively unspoilt. We need critical analysis of ecological factors, aided by laboratory investigations, together with the physiological study of what makes tropical species so much more efficient for the production and maintenance of animal substance than species imported from temperate latitudes.

It was with studies of this sort in mind that, on the initiative of Sir Landsborough Thomson and the Zoological Society, in discussions with the Director of the Nuffield Foundation, a proposal to form a Unit of Tropical Ecology was developed and placed before the Foundation. The Foundation has accepted the proposal and given it most generous and substantial support. The University of Cambridge has readily accepted the proposal that the Unit should be controlled from the University.

The immediate objective of the Unit is to maintain one senior and one junior research worker in tropical ecology to work at the Queen Elizabeth National Park, where the Trustees of the Uganda National Parks already have a small field station. The work of the Unit will, however, be controlled from the University of Cambridge, by a Committee under the honorary chairmanship of Prof. C. F. A. Pantin. The Committee will include representatives from the University of Cambridge, the Nuffield Foundation, the Zoological Society of London and the Trustees of the Uganda National Parks. It is an important part of the scheme that, while the field work will be done in Uganda, the research workers will spend substantial periods planning their work and studying their observations in the Zoological Laboratory at Cambridge. It is hoped that as the scheme develops other research workers will be encouraged to attack problems in Uganda, and also that it will lead to young research workers engaged on such problems coming to work at Cambridge. The authorities of Makerere College have already shown great interest in the Unit.

The Committee will be holding its first meeting early this year to consider staff appointments, and sent Dr. Hugh B. Cott to visit the field station in December and to make a first report. The promoters of the scheme have great hopes that the Unit will lead not only to important work on the ecology, physiology and environmental relations of tropical animals, but also to a greater contact between research workers in Britain and Uganda than has hitherto been possible: further, that the attack on animal ecology may later develop into a broader project, including plant ecology and the study of micro-organisms.

BRITISH COMMUNICATIONS SATELLITE PROGRAMME

IN replying for the Government in an adjournment debate in the House of Commons on December 21 on a British communications satellite programme, which had been opened by Mr. A. Neave, Mr. G. Rippon, the Parliamentary Secretary to the Ministry of Aviation, welcomed the practical approach of speeches in the debate. Previously he had pointed out that communications satellites involve the use of a powerful launcher and that the project is thus distinct from the programme based on *Skylark*, the giant programme in the United States, and also the Preparatory Commission set up to study the possibility of establishing a European space research organization. Both British and American experts are confident that the purely technical problems can be solved within the next few years, and Post Office and Ministry of Aviation scientists and engineers are already carrying out joint work on the design of ground stations and satellites as well as of overall system design. This work is concerned with both technical and economic aspects of satellites. While the co-operation of industry will be sought at the appropriate stage, he did not think that there is anything to be gained by setting up a space communications committee at Cabinet level, as suggested by Mr. Neave.

Mr. Rippon pointed out that many different types of system have been proposed, but experts, both in the United States and in Britain, to-day appear to favour a system using active satellites which will carry radio receivers and transmitters, thus receiving, amplifying and re-transmitting signals instead of just reflecting. He promised to bear in mind what Mr. D. Price had said as to the possibilities of such a system.

The study of system design includes that of the type of orbit to be chosen for the satellites, which could be circular or elliptical, close to the Earth or far away. It is possible to choose a particular circular orbit for a satellite at about 22,000 miles from the Earth, and three such satellites could be so placed that one at least is visible and potentially available for communication purposes from every country in the world, except for certain limited areas near the poles. This system has some disadvantages, and it may well be better to have a larger number of satellites in closer orbit, for example, a dozen or two satellites at 5,000 or 6,000 miles, or 50 at 2,500 miles. Whatever orbit is chosen, there are formidable difficulties, and the technical problems to be overcome make estimates of cost necessarily speculative at this stage. Reliable information on the useful life of a satellite is required, and this can only be obtained by experiment, for which the most promising area is the North Atlantic. Mr. Rippon hoped that such tests will take place in the next year or so, and said that Britain envisages putting two or three satellites into polar orbit. He also said that Britain is aiming at about 1,000 channels for an active satellite, but there is really no limit to the number of channels for a passive satellite.

Meanwhile, Britain will continue with construction of the submarine cables to provide for the communication needs of the Commonwealth, for which a programme, costing between £35 and £40 million, has been approved, covering the cable between Canada and the United States in 1961 and Canada and Australia in 1966. The United Kingdom's share will be less, and it may be found that cable and satellite communications are complementary indefinitely. As regards a launcher, the Government has kept in being those aspects of the *Blue Streak* project which can be of use in developing a satellite launcher. The scientific and technological skills have been preserved, and the teams necessary to develop a satellite launcher retained: should such a launcher be developed, what Britain has done and is doing would enable her, or any other participating country, to formulate a programme and put satellites into orbit within the next five or six years. We have already concluded that, if a heavy satellite launcher were to be developed outside the United States or the U.S.S.R., there are substantial advantages for all concerned in doing so in co-operation with the Commonwealth and Europe. Mr. Rippon directed attention to the fact that Britain is keeping in close touch with Australia and Canada and other members of the Commonwealth, and, if the *Blue Streak* proposals are carried to completion, the facilities at Woomera will be used. The Government has also had lengthy discussions with the French Government on the joint development of a satellite launcher based on *Blue Streak*, and these have gone well. It is intended to ask interested countries to join in a conference early in 1961, and in the meantime individual countries are being invited to send their experts here for discussions and to judge for themselves the technical soundness of the British proposals.

FUTURE OF THE COLONIAL AND THE COMMONWEALTH RELATIONS OFFICES

IN answer to questions in the House of Commons on December 13, the Prime Minister said that he is considering, in consultation with the Commonwealth and Colonial Secretaries, the recommendations regarding the future of the Colonial Office and the Commonwealth Relations Office made by the Select Committee on Estimates, and that the subject will be discussed with other Prime Ministers of the Commonwealth at their Conference to be held during March. Meanwhile, the problem of fusion is being studied to see whether some of the advantages of co-ordination can be secured without the disadvantages of combining relations with independent and dependent members in a single Office. In replying for the Government in a subsequent debate in the House of Commons on December 19, on the Select Committee's report, the Colonial Secretary, Mr. Iain Macleod, said that it is clear that the present policy of leading the dependent territories to full independence as early as is compatible with their educational, political and economic development is bound before long to lead to a stage when there is no longer justification for a separate Office, headed by a Secretary of State, to conduct the relations with the few small remaining dependencies. A Commonwealth Service is another matter, and the preference of the independent countries for independent recruitment and for local officers rather than expatriates destroys the basis of a Commonwealth Service. Meanwhile, the burden of work falling on the two Secretaries of State is too great for a merger to be practical for at least a year or two ahead. Moreover, territories which are reaching independence during the next few years will continue to require in their services expatriate officers in professional, technical and administrative posts, and the supply of such officers concerns both the Colonial Office and the Commonwealth Relations Office.

Ultimately, Mr. Macleod thought, the solution might well lie in the bringing together of the two Offices as the Select Committee recommends, but this is not yet practical politics. Meanwhile, the Government has initiated a study of the possibility of creating a joint Department under a Minister responsible to the Colonial Secretary, the Secretary of Commonwealth Relations and the Foreign Secretary to handle under a single direction many of the forms of technical and advisory assistance which Britain provides to overseas countries whatever their status. Mr. Macleod stressed the importance of the contribution which Britain can make in technical assistance through the experience and knowledge of its men and women. It is accordingly proposed to defer consideration of the Select Committee's proposal for a Commonwealth Advisory and Technical Service pending the result of this examination. Mr. Macleod concluded with a warm tribute to the work of the Colonial Service and to the achievements of what is described as British colonialism. Britain can no longer offer many of the members of the Overseas Service the full cover which they have earned, and it is the Government's duty to ensure that everything possible is done to minimize any consequent hardship. He claimed that Britain has the finest organization in the world for providing professional and technical assistance to underdeveloped territories, and the men and women of the Overseas Service and their predecessors have a record of service of which all should be proud.

Mr. Macleod's tribute to the Colonial Service and his concern for the future of the men and women of the Overseas Service echoed what had been freely expressed in the debate, but although there appears to be widespread support for the merger of the two Offices caution was urged from both sides of the House. There is clearly concern that very big changes will be required in the Commonwealth Relations Office itself before it is fit to deal with the new situation and the needs of the newly independent members of the Commonwealth. In fact, there is much greater confidence in the ability of the Colonial Office to provide the advice, the experience, the skill and techniques that will still be required.

HYDROLOGY IN GREAT BRITAIN

FOR several decades a minority of enthusiasts have pressed on the Government the need for an improved hydrological service in Great Britain. Official recognition of this need was recorded recently in the annual report of the Advisory Council on Scientific Policy, where attention was directed to the fact that Great Britain remains weak in research on hydrology. Yet another warning of coming difficulties in meeting demands on water supply in Great Britain was recently given by Sir Herbert Manzoni in his presidential address to the Institution of Civil Engineers. The position shows every sign of becoming serious in a few years time, and in terms of research a great number of problems are involved throughout the whole of the hydrological cycle; ranging more especially from the effects of vegetation on catchment areas to problems of water use, such as waste by consumers and losses from leaks in water mains. Coincident with these warnings and confirming the need for water conservation and a national water policy, the country has had to endure extensive flooding as a result of one of the wettest autumns on record.

Faced with such difficulties it is pleasing to record some recent advances in hydrological research in Great Britain which it is hoped augurs well for future action. The Surface Water Survey of the Ministry of Housing and Local Government now seems well established and is producing an annual report with admirable regularity. The latest edition[1] covers the water year 1958–59, and includes the flow records of 188 gauging stations of which 19 appear for the first time. There is every indication that this number will rise still further in the next issue as many new stations have recently been established and are now in process of calibration. The water-year covered by the 1958–59 volume is of particular interest as it records the effects of the severe drought of the summer of 1959. The rainfall over England and Wales during the period from May to September was only half the long average for 1916–50, and was probably the lowest for more than 230 years. By the end of September many rivers reached new all-time record low levels; indeed, some dried up altogether.

In addition to the responsibility for an annual return the Surface Water Survey was also charged in 1959 with the preparation of hydrological surveys of selected basins. This duty arose from the recommendations of the Sub-Committee on the Growing Demand for Water[2] that hydrological surveys of river basin areas should be carried out, initially in those areas where the expected surplus of water supply over demand is lowest. Two surveys have now appeared: a few months ago the River Great Ouse Basin (Hydrometric Area No. 33)[3] was published, and more recently the River Severn Basin (Hydrometric Area No. 54)[4] has become available. These reports are notable steps forward in the study of Great Britain's water resources, water use and management. There are still, however, another hundred hydrometric areas to be considered if the whole country is to be covered so that a national assessment of the problem now confronting Great Britain may be made.

Both the surveys which have so far appeared attempt a coverage of all the aspects of the hydrological cycle. There is a general study of the area, population, rainfall, geology, principal rivers and hydrology in the first part of each survey. In the second part the hydrometric area is broken down into five geographical sections in each of which the topography, population, hydro-geology, meteorology, gauging stations, water quality, pollution, navigation, flood protection, irrigation, water use and potential water resources are systematically considered. These descriptive paragraphs are followed in each area by details, both in list and map form, of abstraction of water by public undertakings and by industry, discharges of water by public authorities and by industry, and a water balance sheet. These sections are packed with valuable data which will be of immense value to those concerned with the use of the respective water resources. The third part of each report has a summary and forecast of possible future trends.

The River Ouse survey showed that the basin is one of the driest in Great Britain, and with very few natural sites for storage reservoirs available the continued development of surface water is limited. The main problem that gives cause for anxiety is the rising demand for irrigation water. The chief hope for the future lies in a greater exploitation and at the same time proper management of the ground water resources: these appear to be considerable in some parts of the basin.

The River Severn survey, while following the pattern of the River Ouse survey, is more ambitious in that estimates are given ahead to 1980. Covering an area of 4,410 square miles the River Severn Basin reaches from Rugby to Lake Vyrnwy and from Shropshire to the Bristol Channel. It is the largest river basin in Great Britain and has a mean run-off of 2,200 million gallons per day. At present the river basin supports a total water use of 737 million gallons per day for almost 2 million people: of this some 121 million gallons per day are permanently abstracted for use in the area and another 43 million gallons per day are exported without serious consequences as to the remaining quantity or quality of the river water even during prolonged periods of dry weather. The report suggests that maybe another 10 million gallons per day could be taken without noticeable effects during a drought, but that the abstraction of an additional 50 million gallons per day would certainly produce difficulties, while an additional abstraction of 100 million gallons per day might at times dry the river above Bewdley and produce objectionable conditions downstream.

Proposals have already been made by public water undertakings for the construction of works capable of abstracting an additional 100 million gallons per day, so that total abstractions for the mid-1960's could amount to 260 million gallons per day, on top of which has to be added increased direct abstraction by industry and by agricultural interests for irrigation. By 1980 it is anticipated that abstractions could rise to 370 million gallons per day with possibly 64,000 acres under irrigation.

The report makes it clear that these increases can only be achieved by additional storage, controlled use, and a policy of integrated river basin development. The authors reject the extensive use of conventional storage reservoirs and pumped storage schemes and come down in favour of regulating reservoirs, with which, it is maintained, an additional 250 million gallons per day could be guaranteed, an adequate flow in the Severn preserved at all times, much agricultural and urban land protected from flooding, and up to 64,000 acres irrigated in times of drought.

W. G. V. BALCHIN

HYGIENE AND PLANT PROTECTION

THE chemical means of plant protection and problems of hygiene have been reviewed by L. I. Medved, director of the Kiev Institute of Labour Hygiene and Occupational Diseases, in a recent issue of *Impact of Science on Society* (10, No. 4, 1960).

The systematic fight against pests and diseases of cultivated plants is not only of great economic importance, but is also socially significant. It has been calculated that the loss of food and technical crops on the farms of the United States due to pests, fungoid diseases and weeds amounts to about 11,000 million dollars a year. Similarly it has been shown that implementation of measures for the protection of plants against pests, diseases and weeds would make an additional quantity of agricultural produce, valued at about 54 billion roubles, available in the U.S.S.R. While the quantity of pesticides produced and employed in agriculture by either of these two countries is considered greater than by any other, and, if they possess enormous reserves for increasing agricultural produce as a result of further use of pesticides, the same opportunities exist in other countries.

The beneficial aspect of the use of poisonous chemicals in agriculture is evident, but the social effects should not be overlooked. All, or almost all, the chemicals employed are biologically active, and in some cases are potentially poisonous for human beings. Investigations by Soviet scientists have shown that the prolonged action on the human organism of various chemical substances, even in insignificant quantities, may lead to a fall in the reactivity of the organism and to a rise in susceptibility to other diseases. In such cases, acute and chronic intoxication does not occur, but a general high level of morbidity is noted.

The problem of the carcinogenic effect of certain chemicals requires special attention. There are indications that carbolineum and its preparations, employed in a number of countries, contain a carcinogenic impurity (benzpyrene). There have been reports on the carcinogenic properties of *iso*-propylic ether of 3-chloro-phenylcarbamic acid, applied as herbicides in a number of countries. Concern is felt in the United States about the carcinogenic properties of certain organochloric insecticides.

The danger of chemicals to public health does not lie only in the possibility of accidents (acute intoxications). The chief danger to the health of the population lies in the prolonged chronic action of certain preparations inducing pathological states which are not ordinarily diagnosed as intoxication. Considerable data have been presented by American investigators on the rise in the incidence of diseases of the liver and gastro-intestinal tract, and of cardiovascular and nervous diseases among the population of the United States and a number of other countries, as a result of the extensive use of DDT and other organochloric compounds.

The duty of toxicology as the science of the toxic properties of chemical substances is not only to determine the lethal doses of one substance or another, but also to ascertain the possibilities of its chronic effect on the human organism over a prolonged period of intake in small quantities. A preparation which is widespread throughout the world, like DDT, has only a slightly toxic effect on the organism in a single dose, and the probability of poisoning with a lethal outcome is insignificant. When taken into the organism in various ways, however, DDT accumulates in the fatty tissues and is retained in them for a long time. Even in slight quantities, DDT acts very slowly, but destructively, on the organism. The increase in liver disease incidence observed in many countries is to a certain extent due to the intensified use of DDT and other organochloric insecticides.

Investigations conducted in the toxicological laboratory of the Kiev Institute of Labour Hygiene and Occupational Diseases have shown that DDT, chlorindane, hexachlorane, heptachlor and other organochloric preparations, even when taken into the organism in small quantities, accumulate in it and afterwards give rise to various diseases. The investigations of the Ukrainian Institute of Nutrition have shown that, if a plant is treated with DDT during the period of fructification, the preparation is retained for a long time in the fruits. When milch cows are given repeated treatment to combat blood-sucking insects, DDT is eliminated in the milk during a period of over three months in quantities endangering the health of people consuming the milk. DDT does not break down under natural conditions or as a result of cooking. On the basis of the results obtained in these investigations, the State Sanitary Inspection of the U.S.S.R. has adopted an enactment prohibiting the treatment of plants with DDT during the period of fructification and providing for other restrictions.

GAS CHROMATOGRAPHY: DEFINITIONS AND RETENTION PARAMETERS

LEADING workers in gas chromatography soon realized that published retention data would have much greater value if they were reported in a manner which made quantitative comparison possible, and in 1956, at the first committee meeting of the Gas Chromatography Discussion Group of the Institute of Petroleum Hydrocarbon Research Group, a sub-committee was formed to consider recommendations on presentation of data. Although differences between the views of this sub-committee and American workers were settled early in 1958, it was evident that international agreement was desirable, and approaches to the International Union of Pure and Applied Chemistry resulted in the formation of a Task Group to consider the matter. In addition to presentation of data, the Task Group also considered nomenclature, its terms of reference being to encourage the use of established conventions provided they were consistent with accepted theory, to select a single term where several existed, and to eliminate ambiguity of definition. The preliminary report of the Task Group was made available to the Discussion Group early in 1960 and has now been published in *Pure and Applied Chemistry*, the journal of the International Union.

At an informal symposium held at the University of Liverpool on October 21, where the Discussion Group was welcomed by Dr. G. Skirrow, the International Union of Pure and Applied Chemistry recommendations were discussed, and papers on alternative methods of presentation were read. The chair for the morning session was taken by Mr. C. S. G. Phillips and for the afternoon session by Mr. R. P. W. Scott.

After reviewing the historical background and acknowledging a valuable contribution to the work by the Groupement pour l'Avancement des Méthodes Spectrographiques, Dr. D. Ambrose, chairman of the International Union Task Group, discussed some of the points which had been considered in drawing up the recommendations summarized below.

The technique of gas chromatography is divided into gas–liquid and gas–solid, depending on whether separation is effected by partition or adsorption. Definitions are given for the following terms: sample injector, column (solid volume, liquid volume and interstitial volume), detector (differential and integral), carrier gas, liquid phase, solid support and active solid. In gas–liquid chromatography the stationary phase comprises the liquid phase without solid support, and in gas–solid chromatography the stationary phase is the active solid. On the chromatogram, base line, peak, peak base, peak area, peak height, peak width and peak width at half-peak height are defined and illustrated. The Martin and James pressure gradient correction factor is designated j. Uncorrected and corrected (factor j applied) retention volumes measured from the point of injection are respectively V_R and V°_R. The uncorrected retention volume for a non-absorbed gas is termed gas hold-up, V_M. The adjusted retention volume V_R–V_M is designated V'_R and becomes net retention volume V_N when the correction factor j has been applied. These parameters are reported at the column temperature. Specific retention volume V_g is the net retention volume per gram of liquid phase corrected to the volume at 0° C.

Retention data should be published on an absolute basis or relative to a pure solute for which an absolute value is known at the operating temperature, and, wherever possible, the variation with temperature should be reported. Relative retention r of two components is given by:

$$r_{1,2} = \frac{V_{g_1}}{V_{g_2}} = \frac{V_{N_1}}{V_{N_2}} = \frac{V'_{R_1}}{V'_{R_2}} \neq \frac{V_{R_1}}{V_{R_2}}$$

The theoretical plate value n of a column is used to express column performance (previously referred to as column efficiency), and peak resolution is given by twice the difference between retention (in volume, time or distance) divided by the sum of the peak widths in the corresponding units. Sample size, method of injection, and detector dead volume are factors which can affect the values obtained for retention parameters, column performance and resolution unless corrected for. The recommendations are preliminary and the Task Group is to exist for at least another two years; comment and suggestions will be welcomed by Dr. D. Ambrose (National Chemical Laboratory, Teddington, Middlesex, England).

Mr. G. R. Primavesi (Distillers Co., Ltd.), expressing the views of an analyst on the presentation of data, maintained that whatever terms were used they should be relative as well as absolute, and that chart distance took pride of place over time or volume. The theoretical treatment of Martin and James was adequate, although the analyst had no need for the term V°_R. Retardation volume was preferred to net retention volume, and a plea was made that the expression for calculating j be published in a form which could not be misinterpreted. Mr. Primavesi commented on the modes of presentation of specific retentions, and expressed the view that it was more convenient to have retention data measured at the column temperature.

Replying to these and other comments which had been received, Dr. Ambrose stated that, although the relation of partition coefficient to retention data is included in the recommendations, it is not regarded as a retention parameter but merely as an example of one of a number of physical constants which can be determined by gas chromatography. The Task Group had taken as a fundamental experimental quantity the retention volume V_R, which is a volume of gas; the fact that the actual measurement was made in time or distance was irrelevant. The term V^{0}_R was retained with its original definition on historical grounds but with the qualification that "this quantity is of limited use because it is influenced by the volumes of sample injector and detector as well as the interstitial volume of the column", because Martin and James made no mention of the significance of measurement from the air peak and, in fact, defined the ratio V_{R_1}/V_{R_2} as relative retention. Some confusion had arisen over the use of the term V_g; it had been used to describe specific retention per gram at the column temperature and at 0° C. There was very little to choose between the two interpretations, and the latter was chosen for recommendation because flow-meters are usually calibrated at 0° C and the plot of V_g at 0° C. against $1/T$ is linear. Authors are advised to indicate the definition of V_g used when reporting results.

Speaking as a teacher requiring a logically correct approach to theory, Prof. P. Chovin (Laboratoire Municipal, Paris, and chairman of Groupement pour l'Avancement des Méthodes Spectrographiques) preferred to develop it from an ideal column without external dead volume in which retention volume is a 'true' value. This concept does not affect adjusted, absolute and specific values. However, in the case of column performance where retention is measured from the point of injection, comparison of the 'true' and 'real' values gives valuable information on the loss of performance resulting from parts of the apparatus external to the column. The difficulties associated with the measurement of effective injector and detector dead volumes limit the practical interest in 'true' retention parameters. Prof. Chovin also discussed a new parameter, net retention volume per mole of liquid phase, and its application to the determination of activity coefficients. If the activity coefficient of a solvent–solute system at a given temperature was known, the value for the same solute with a different solvent could be determined very simply, and for this purpose a dual column assembly in one vapour jacket had been used.

In a paper by Mr. R. L. Martin (Standard Oil Co., of Indiana), read by Dr. A. Goldup, work was described which was interpreted as indicating adsorption effects at the liquid–gas interface. Such a phenomenon seriously affects the derivation of partition coefficients and other derived thermodynamic functions unless corrected for. In some circumstances the correction could amount to more than 80 per cent of the measured retention volume. With packed columns it had been found that the order of elution of hydrocarbon solutes varied with the amount of liquid phase, and the plot of retention volume per gram of column-packing versus liquid-phase percentage did not extrapolate to zero retention at zero liquid phase. With non-polar liquid phases the deviations were small and were attributable to adsorption on the support. With polar liquid phases the deviations were considerably larger and varied with the liquid phase. Using values for liquid surface area obtained by subjecting the coated support to the gas chromatographic continuous-flow method for surface area of solids, retention volumes were accounted for as the sum of a contribution by solution in the liquid (partition coefficient × volume of liquid) and a contribution by adsorption on the surface of the liquid (adsorption coefficient × surface area of liquid). The contribution by solution increased linearly with increase of liquid phase, but the contribution by adsorption decreased due to the decrease in liquid surface area as the percentage of liquid phase increased. Calculated 'adsorbabilities' for saturated hydrocarbons on polar liquid phases bore an inverse relation to the surface tension of the hydrocarbons. It was also noted that column performance was considerably greater with liquids on which adsorption occurred.

Mr. W. T. Swanton (British Petroleum Co.) questioned the validity of some of the arguments, and indicated that effects due to the solid support, uncoated support in particular, should be considered carefully. The relative values obtained for some of the 'adsorbabilities' were also queried; static experiments and application of the Gibbs adsorption equation might clarify the position. Further discussion on this interesting paper was limited by the absence of the author.

Dr. E. Kovats and Dr. J. F. Smith each presented methods for reporting data which go a long way towards solving the difficulties of analysts, who so often find that their extensive collection of relative values is of limited application because it lacks a common denominator relating the different standards which have been used to cover liquid phases of diverse type and a variety of temperatures.

In the Retention Index Scheme proposed by Dr. Kovats (Laboratory for Organic Chemistry, Zurich) the retention of a solute is given as a value obtained by logarithmic interpolation between the values for two even-numbered *n*-alkanes which, for convenience, are assigned values equivalent to one hundred times their carbon number. The good repeatability and reproducibility of the method were illustrated with the aid of values calculated from retention data published by other workers; however, as with other forms of retention data, possible effects of solid support must be considered and care taken in standardizing on a reproducible support. Except for small molecules such as methanol and nitroethane, where the functional group dominates, the variation of retention index with column temperature is small and linear—about four units per ten degrees centigrade. From the results of a large number of determinations, the difference between the retention indexes of two close-boiling isomers is deduced as five times the difference between their boiling points (°C.). Retention indexes increase by one hundred units on both polar and non-polar phases for the higher members of any homologous series with the insertion of a $-CH_2$ group. Differences in values obtained on polar and non-polar phases can be ascribed to solute type. For non-polar hydrocarbons the difference is zero. Dr. Kovats presented evidence that bonding types and functional groups in a molecule can each be assigned a difference value, which for a given polar liquid phase are additive.

With Dr. Smith's theoretical nonane or R_{x9} method, which has been used extensively and proved invaluable in the laboratories of the Natural Rubber Producers' Research Association, all values are expressed relative to the retention time for *n*-nonane, which is obtained by extrapolation or interpolation from the logarithmic retention time versus carbon number plots with *n*-alkanes. A simple relation between the R_{x9} value and the retention index was shown to exist. Statistical examination of the results obtained for various chemical classes on squalane and dinonyl phthalate at several temperatures showed that the repeatability for the whole calibration procedure and determination of relative value were at least as good as for methods involving the use of one or more standards within the chromatogram.

C. G. SCOTT

CONDITIONING AND ELECTRO-PHYSIOLOGY

A PAVLOVIAN Conference on "Higher Nervous Activity" was held during October 13–15 in New York, under the auspices of the New York Academy of Sciences and the Academy of Medical Sciences of the U.S.S.R. This Conference follows, in its main lines, a number of recent international meetings such as the Moscow Colloquium on "Electroencephalography and Higher Nervous Activity", the Montevideo Symposium on "Brain Mechanisms and Learning", and the Macy Conference series on the "Central Nervous System and Behaviour". These Conferences have been promoted because of widespread belief, explicitly stated by Magoun in his contribution to the New York Conference, that "the most striking recent progress in the biology of Higher Neural Activity has unquestionably come from electrophysiological analyses of the mechanism of learned behaviour. Knowledge has especially been advanced by marriage between the electrical recording techniques of Western neurophysiology and the classical Pavlovian approaches to the study of conditioned reflexes cultivated so extensively in the U.S.S.R.". The proceedings of the entire meetings will be published in the *Annals of the New York Academy of Sciences*. Attendance at the meetings averaged about eight hundred persons on each of the three days.

How does this Conference conform to a reformulation of Parkinson's law, namely, that regardless of new material available the number of words spoken at a conference will expand to fill the *Proceedings* published a year or two later? On the whole, expectations are fulfilled. There are some semi-philosophical discussions "on the relationship between neurophysiology, psychophysiology, psychopharmacology and other disciplines", which are not likely to throw much light on the difficult task of analysing the cortical and subcortical events taking place during conditioning. We have a rather expanded account of "The Role of Slow Waves in Differential Inhibition" based on records obtained from electrodes implanted with unknown accuracy "in the visual cortex, auditory cortex, medial suprasylvian cortex, dorsal hippocampus, ventral hippocampus, mesencephalic reticular formation, centralis lateralis, centre median, medialis dorsalis, and the lateral geniculate body" of two cats in which the conditioned avoidance response to flickering light was established. The results of this "admittedly crude and exploratory pilot study" are not particularly informative; conclusions are of the nature that "our electrographic data indicate that cortical slow waves are associated with inhibition, although they do not preclude excitation"; and we also have "The First Law of Bio-Cybernetics: Unidirectional Rate Sensitivity", which attempts a mathematical expression of heart-rate and pupillary reflexes. This paper will, no doubt, appeal to mathematicians familiar with Laplace operators, but will leave most biologists doubtful about the applicability of this type of analysis to sets of data still very much in search of appropriate causal factors.

From the point of view of the Western reader, no doubt the most interesting and important papers will be the Russian ones, particularly those by P. K. Anokhin and E. A. Asratyan. These not only give a summary of work done over the years in the laboratories of these two contributors but also report work which, to the present reviewer at least, was unknown and interesting.

Anokhin, after directing attention to the fact that many years ago Pavlow had already emphasized the importance of subcortical centres in ensuring a "high energy level for the functional interactions among the cortical elements", began his talk "with a formulation of some perfectly obvious contradictions which are now arising between the basic ideas of modern instrumental neurophysiology and the physiology of higher nervous activity. . . . The main contradiction is in the understanding of the essence of the ascending non-specific activity effect of the reticular formations of the stem and thalamus on the cerebral cortex". The problem, as it appears to Anokhin, is this: "The generally accepted interpretation of this phenomenon assumes that this effect is generalized throughout the entire cortex and probably all the cortical cellular elements. *Desynchronization*, that is, transformation of the slow-wave and high-amplitude electric activity into low-amplitude and high-frequency electric activity, is usually regarded as electrophysiological expression of this generalized activation. . . It is silently assumed that this activity concerns *all the cell elements of the cortex*, hence, its designation as 'diffuse' activity".

This diffuse and non-specific activity contrasts with the very highly specific formation of conditioned reflexes, that is, the creation of "the temporary bond between the given stimulus and any inborn activity of the organism". As Anokhin puts his problem: "How can generalized and apparently diffuse activation of the cerebral cortex be combined with the finest selective interactions between the cortical elements down to and including individual synaptic contacts?" Anokhin's very lengthy address summarizes the extensive work of his school relating to this problem, which has proceeded along two main lines. In the first place he has made a comparative evaluation of the activating effect of the cerebral cortex under conditions of two biologically opposed states of the animal—defensive and alimentary; and secondly, he has worked by means of stereotaxic placement and micro-electrode techniques of evoked potential. He studied "the ways of the ascending influences on the cortical element under different pharmacological effects and at different stages of ontogenetic development". The results of all this work are interpreted by him as throwing considerable doubt on the notion of 'diffuseness' as applied to the activating effects of the subcortical structures.

Asratyan is concerned with "The Question of the Initiation and Localization of Various Types of Cortical Inhibition in the Elements of the Conditioned Reflex Arc". He opposes both the two traditional views, that is, "that conditioned inhibition is initiated in the cortical nerve cells of the focus of the conditioned stimulus", as well as the alternative view, "that conditioned inhibition is initiated in the nerve cells of the focus of the unconditioned stimulus". (He also rejects the view of Kupalov, which combines these two hypotheses.) Asratyan's own theory amounts to saying "that conditioned inhibition is initiated primarily in the elements of the conditioned connexion itself, which we represent as a chain of internuncial neurones". Most of the work he quotes in support comes from experiments on "transswitching"; this term is used by him to designate an experimental paradigm in which ". . . a single indifferent stimulus is given two different signal values at the same time. This is done by reinforcing the stimulus differently in two different experimental conditions or situations". These experiments are interesting, but scarcely conclusive; Asratyan does not, for example, discuss at all the difficulties which would be presented for his theory by the results of Culler's classical experiment of 1938.

It is noteworthy that, while the American and Russian participants at this Conference do occasionally take notice of each other's work, yet in the main there is no real bridge from one group of workers to the other. This may be a question of nationality and politics; but other possibilities spring to mind. Electro-physiologists in the United States, and in Great Britain too, pay just as little attention to the work, or the contribution, of Western psychologists active in the field of modern learning theory and conditioning as they do to the Russians; the encapsulation of separate disciplines is more likely to be the villain of the piece, rather than national or political prejudices.

H. J. EYSENCK

THE CHANGING INDUSTRIAL ENVIRONMENT

THE theme of the annual conference of the Institute of Personnel Management which was held at Harrogate during October 7–9 was "People and Machines".

Various developments in personnel management and industrial relations were considered by the 1,200 individuals who attended from industrial companies, local and central government departments, universities and other higher educational institutions throughout the world. The tone and conduct of the conference were again on such a high plane that it is bound to have far-reaching consequences. Responsibility for organizing a conference which, outside those of political parties and trade unions, is probably the biggest in Great Britain lies mainly with Miss H. E. Cutting, who must be congratulated for the quietly efficient way in which these conferences take place.

The opening address was given by the newly appointed Minister of Labour, the Rt. Hon. John Hare, who, after reviewing the general principles on which the Government acts in the field of industrial relations, described the measure of success which stems from the British system of free negotiation. In the twelve months from June 1959 to June 1960, for example, more than 300 important claims for increased wages or shorter hours covering practically the whole of industry were settled peacefully, while less than ten resulted in disputes which led to strikes.

Strikes can be put broadly into two categories. First, there are strikes over clear-cut economic issues affecting wages or conditions of work. These, if they take place after the procedure of negotiation has been followed and failed to produce agreement, are one of the consequences to be accepted as inevitable from time to time in a free society where those who work have the right and power to seek the conditions of employment they feel that they are entitled to.

The second category contains the large number of strikes in individual establishments over a wide variety of difficulties, not only wages, which arise between management and labour or between different groups of workers. They arise over such issues as discipline, dismissals, redundancy, working arrangements and union membership. The causes of many of them are sometimes obscure—at least to the general public. Most of them are unofficial.

This second category of strike has recently given rise to public criticism. Industry itself, both employers and trade unions, is gravely concerned about them. Mr. Hare indicated that these criticisms and fears are justified because these strikes indicate continuing weakness in the present system. The Minister recommended that the two sides of the motor-car manufacturing industry should set up a top-level study group, or informal committee, to produce constructive proposals for overcoming the problems which cause regrettable stoppages within the industry—whether these problems arise on the management or the workers' side. The Minister indicated his readiness to help such a group.

At one of the sectional meetings the issue of whether collective bargaining should be carried out nationally or locally was examined. Prof. E. H. Phelps Brown showed how, in the years of full employment since the Second World War, there has been a substantial increase in the extent to which actual terms and conditions of employment are regulated by bargaining between firms and their own workpeople. Much of our collective bargaining now has a two-tier structure: from time to time each employee gets a rise the amount of which is fixed by an industry-wide bargain, but this actual rate depends also on a bargain struck within the firm. The procedure by which these local agreements are reached vary widely, and many are informal, but, in one way or another, they involve negotiation between a firm's management and its own work-people.

Is this development to be welcomed or resisted? Negotiation firm by firm avoids the danger of industry-wide bargaining and that rises in money wages will be granted too readily, because all competitors will have to pay them and so expect to be able to cover them by a general rise in selling prices. On the other hand, there is a danger that the different rates for the same job in different firms will give rise to unrest and whip-sawing.

Mr. G. Moxon, of United Glass, Ltd., was firmly against any proposal to decentralize wage-rate bargaining. Such a proposal presents a major change to the established and traditional system affecting all companies in some degree or other, but affecting most markedly multiple companies with factories in different parts of the country.

Moxon's objections to the proposal may be summarized as follows: there is no evidence that the decentralization of wage negotiations would result in more acceptable bargains than is the case under the present system. On the contrary, it is at least possible that disputes would increase and factory relations would become worse if wage-rate bargaining were brought to the factory floor. There is no evidence that the decentralization of negotiations would diminish such tendencies as there are to a wage–price spiral; decentralized wage-rate bargaining is likely to have the effect of transferring a good deal of responsibility for bargaining away from the senior ranks of trade union officials (for example, national officers), into the hands of less-experienced, and sometimes less-successful, officials at plant-level where shop stewards will exercise a considerable influence; factory bargaining for increases beyond minima would necessitate some unified body of unions to negotiate on a common front with company management. This would mean a unified body embracing craft and general workers' unions. Without this safeguard, management would be exposed to leap-frog tactics by the various unions with which it negotiates.

The education and training of technicians were elaborated by Mr. J. S. Newton of Pilkington Bros., who used sections of the Crowther Report to distinguish between the craftsman, technician and technologist. The former has sufficient skill to make components, the second has enough training and industrial experience to supervise the carrying out of various skills, and the technologist has sufficient training to apply highly complicated scientific and technological methods to production. The technician has been brought into existence in order to solve a two-fold problem: (*a*) craftsmen in modern times are being asked to tackle work beyond their scope; (*b*) highly trained men are being wasted on work requiring much less potential. The technician must have extensive grounding in many skills, and must be intellectually more able than the craftsman. He must supply the 'know-how', and acquire the arts of communication and management. He forms the vital link between the other two grades

Industry must decide what its requirements are in each grade, and begin by careful selection for each grade, considering educational qualifications along with general background. This may help to decrease the failure-rates between commencing and finishing a college course.

Training given at work must be carefully planned, and watched closely if it is decentralized; trainees should not be used as cheap labour. The training officer must have a clear-cut policy to implement, and planning and reports must be centralized. If training is centralized, it must not be isolated from production. If it is decentralized it must be on a systematic basis, with set periods under different operator/trainers, who must be paid special rates so that their earnings do not suffer. Industrial training must supply the trainee with as wide a field of experience as possible, filling in gaps with short-period visits to other factories, on an exchange system. Trainee technicians must have early experience of dealing with emergencies. Training must be devised to develop and mature their personalities.

The British contribution to the development of personnel management in newly industrializing countries was discussed by two speakers with considerable experience overseas. Mr. F. J. Pedler, of the United Africa Co. Ltd., declared that the golden rule for staff relations is to treat African workers in Africa as one would treat English workers in England. "If one begins by treating an African trade union as one would treat a respectable trade union in England one cannot go very wrong." The assumption is too commonly made that trade unions in Africa are subversive, communist, corrupt and unrepresentative. Some African trade unions are fully responsible. It is true that some are dominated by communists, and others, without being communist, are identified with political parties in their own country. The influence of Israel on trade union structure has been strong in some African countries.

Employers should be bold and sympathetic in recognizing unions and helping them to develop along the right lines. The technique of a joint industrial committee, for example, has been widely used in Africa with success.

The basic fact about African labour is that it is very scarce. It has to be managed as a scarce commodity, as it already commands the price of a scarce commodity: the position in Africa is very different from India.

It is important that political urges and economic development should be brought into harmony and made to serve useful ends. In this problem, personnel management has a big part to play. Such management must handle the basic problem of labour scarcity in such a way that the cost of wages and fringe benefits do not put a brake on investment.

The training of staff at all levels is essential. One of the important things which England can pass on to Africa through good personnel management is the conception of a commercial company as a community of men united for a common purpose: and, within the larger community, the conception of each unit—whether it be a department or a training school —as a team in which there are corporate interests. The most important step in achieving such a spirit is to promote Africans to be managers and to associate them fully in running the business.

Mr. John Marsh, Industrial Welfare Society, suggested that, in helping the development of personnel management in countries overseas, the British contribution should insist that our daily practice in industry and commerce should be an example. This is particularly true if the British control or administer expatriate enterprises in foreign lands.

Personnel officers and other managers who serve abroad for a portion of their lives are especially important as ambassadors of modern Britain. The Government is making a special effort to ensure that teachers going to the Commonwealth should have safeguards in their future careers, and Civil servants serving in other lands are now more satisfactorily protected. Service in industry and commerce overseas is still a handicap instead of a credit to a man's career. By sharing our knowledge and experience with indigenous managers and specialists sent to the United Kingdom for training and development, Britain makes a considerable contribution to the development of good industrial relations overseas.

The closing address was given by Sir Ben Lockspeiser, of Tube Investments, Ltd., who described the evolution of machines manufactured by man to create the environment in which he now lives. But, although man is good at designing machines, he is not so good at understanding human behaviour, and the introduction of electronic machines could have lamentable social consequences if the personal problems involved are neglected. Many people are bound to be affected personally. Considerable changes of technique cannot be brought about overnight. The period of adjustment is long enough to give those in authority the opportunity of using the means at their disposal, such as retraining schemes and the adaptation of recruitment and wastage-rates, to anticipate consequences and work out the necessary human measures to meet new circumstances. Good personnel management must accompany a developing technology.

T. H. Hawkins

EPIDEMIOLOGY OF BLACK RUST OF WHEAT

A SYMPOSIUM on "Epidemics of Black (Stem) Rust of Wheat" was held in the afternoon of October 7 under the auspices of the British Mycological Society. Mr. L. Ogilvie (National Agricultural Advisory Service, Bristol) said that the alternate host of black rust, wild barberry, does not appear to be implicated in the origin of uniformly distributed and almost simultaneous epidemics in the south-west of England. It was therefore decided to find whether uredospores are transported from the Continent in the same way as they are carried northwards from Texas into the American wheat belt.

Collaborative investigations which have been proceeding in Western Europe and North Africa since 1958 show that the disease overwinters in the uredospore stage on wheat and grasses in North Africa and Southern Iberia, and spreads northwards in summer. Observations on field crops and on some thirty widely scattered 'rust nurseries' (small plots of varieties of spring wheats) were organized from Bristol. About a fortnight after uredospores were trapped in quantity, rust was found in the fields and from then on became common in most of the southern coastal areas, the Channel Islands and Isles of Scilly and, later, to a lesser degree, in the whole of the southern half of England.

Dr. I. G. Thorpe (National Agricultural Advisory Service, Bristol) stated that the oat, barley, and some grass varieties of *Puccinia graminis* are not uncommon on barberries in England, but the wheat variety has not been found in recent years. The simultaneous appearance of the disease over a large area suggests a widespread inoculum. Uredospore deposits on spore traps can usually be correlated with air trajectories from countries to the south, as is explained later. Up to the present, the spectrum of rust races recognized in England greatly resembles that of the Iberian Peninsula and France. Mr. H. A. Hyde and Mrs. K. F. Adams (National Museum of Wales, Cardiff) reported that black rust uredospores have been found from May onwards in the spore catches organized by the Asthma and Allergy Research Unit at Cardiff and the Bishop Rock Lighthouse, often before wheat is affected in England. Simultaneous catches of black rust spores have often been made at points more than 150 miles apart. The theory of spore clouds originating from the Continent is supported also by catches in spring of pine pollen, which apparently came from southern Europe.

Mr. W. H. Hogg (Meteorological Office, Bristol) described how air trajectories could be prepared from weather maps, and gave estimates of the errors involved. Uredospore catches in London during the period July 4–10, 1959, were accompanied by air trajectories from the Continent. When the air came from other quarters, spores were few or lacking. Dr. J. M. Hirst (Rothamsted) dealt with theories underlying the liberation, transport and deposition of rust uredospores. Sampling from aircraft traversing southerly airstreams over the English Channel have shown large numbers of spores at heights up to 7,000 ft.

Conclusions which may be drawn from the symposium are that a severe black rust epidemic in England depends on susceptible varieties of wheat (all varieties grown here are susceptible to the common West European races of black rust), lateness of the wheat crops, transport of spore clouds arising from epidemics to the south by one or more favourable wind trajectories in late June or early July, and warm and humid weather at the time of infection and for several weeks later.

TROPICAL ECOLOGY

ECOLOGICAL terminology and concepts applicable to, and developed under, temperate conditions sometimes have little relevance to the vegetation of the tropics, and a journal devoted especially to tropical ecology will be welcomed by many as meeting a real need, so long as it does not encourage ecologists in differing climatic zones to overlook the essential unity of their subject.

Nos. 1 and 2 of Vol. 1 of the *Bulletin of the International Society for Tropical Ecology* give little indication of the extent to which this new journal will, in fact, meet the need which undoubtedly exists. No. 1 contains a presidential address: "Why Tropical Ecology?" by J. C. Sen Gupta, as well as abstracts of 22 papers, mainly on tropical forests, given at a symposium on forest ecology held at Bombay. In No. 2 are rather longer accounts of 21 papers read at a forest ecosystem symposium which was a part of the ninth International Botanical Congress held at Montreal. There is thus an absence of research papers of the conventional type; but it is useful to have the views of experts from many countries on forest classification assembled together in a single volume in this way.

No indication is given as to whether succeeding numbers of this journal will be restricted to abstracts of papers read at symposia and conferences, or whether the journal is to restrict itself to tropical plant ecology. Until it is possible to see what permanent form this new journal takes, it can be given only a qualified welcome, although a forum in which ecologists of the tropics can discuss their special problems and report on their work is undoubtedly needed.

The *Bulletin* is edited by Dr. G. S. Puri, general secretary of the Society, 10 Chatham Lines, Allahabad, India, assisted by an editorial board with representatives from Japan, India and Great Britain. It is not priced, but is distributed to members of the Society (annual subscription 15 rupees, or £1 2*s*. 6*d*.).

OBSERVATIONS OF FALL-OUT IN INDIA DURING THE PERIOD OF CESSATION OF NUCLEAR TESTS

By K. G. VOHRA and V. S. BHATNAGAR

Atomic Energy Establishment, Trombay, Bombay

THE recent measurements of fall-out in different parts of the world have provided evidence of a shorter time of residence of fission products in the stratosphere than had been estimated earlier[1-5]. Martell[1,2] has suggested residence-time in the stratosphere of 6 months–1 year for the tests carried out in the polar regions and 3–5 years for the tests carried out in the equatorial regions. The investigations on fall-out carried out in Norway[3] have shown that the airborne activity at the ground-level starts increasing shortly after high-yield tests, reaches a peak value in about six to seven months and then decreases with a half-life of about one month. These measurements also suggest a short value of mean residence-time in the stratosphere.

The ground-level airborne fall-out activity in India[6] after October 1958 showed a trend somewhat similar to that observed in Norway. A rise in airborne activity was observed soon after the completion of high-yield tests carried out in the polar regions in October 1958. This increase continued, and a maximum was reached at all the stations after about four months, that is, during February–March 1959. This activity decreased with a half-life of about 40 days, suggesting residence-time in the atmosphere of about 60 days.

We have also studied the ratio of zirconium-95 and cæsium-137 activities in samples of rain-water from Srinagar and Bombay during the period December 1958–September 1959. The change in this ratio with time seems to provide some information regarding the relative proportions of fall-out debris from the old tests and the October 1958 polar tests. The mean residence-time in the atmosphere has also been estimated indirectly from this ratio and is found to be about 60 days.

The obvious consequence of short residence-time in the stratosphere is an increase in the external gamma-radiation dose for several months after high-yield tests. The radiation dose from the gamma-emitting isotopes (zirconium-95 + niobium-95), (cerium-144 + praseodymium-144), ruthenium-106 and cæsium-137 after the October 1958 test series has been estimated from the observed levels of activity.

Airborne Radioactivity

Fig. 1 gives the concentrations of radioactive fall-out fission products in the air at ground-level at different stations in India for the period October 1958–June 1959. The airborne radioactivity shows a steady increase after October 1958, reaching a peak value in about four months. The peak in activity is observed at all the stations, except Ootacamund, during the months of February and March, after which the activity decreases with a half-life of about one month.

The increase in activity to the peak value during the period of about four months after the October 1958 test series may be explained as due to the storage of the debris in the troposphere determined by the mean residence-time in the troposphere, which is of the order of 20–30 days. The decrease in airborne activity at ground-level will be governed by the trend of decrease in the troposphere, which in turn would depend on the residence-time in the stratosphere.

The levels of airborne radioactivity averaged for all the stations for each month and corrected for radioactive decay to October 15, 1958, have also been plotted in Fig. 1, and a smooth graph has been drawn through these points to give a picture of the general trend of variations of airborne activity at ground-level. This graph shows that, after the peak is reached, the activity decreases with a half-life of 40 days, as determined from the slope, corresponding to a mean residence-time in the atmosphere of about 60 days.

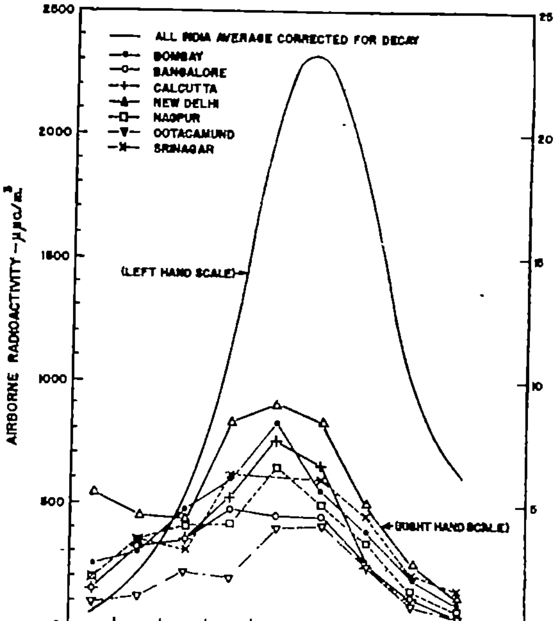

Fig. 1. Average monthly levels of airborne radioactivity at different stations in India during October 1958–June 1959. The smooth curve shows the level of airborne radioactivity averaged for all the stations for each month and corrected for radioactive decay to October 15, 1958

Table 1. INFINITY EXTERNAL GAMMA-RADIATION DOSAGE FROM THE MONTHLY DEPOSITION ZR-95 NB-95, CE-144 PR-144, RU-106 AND CS-137 AT SRINAGAR DURING OCTOBER 1958–JUNE 1959

Month	Zirconium-95 + niobium-95 (m.rems)	Cæsium-144 + praseodymium-144 (m.rems)	Ruthenium-106 (m.rems)	Cæsium-137 (m.rems)	Total (m.rems)
October	0·14	0·039	0·048	0·76	0·99
November	0·22	0·048	0·026	0·81	2·11
December	1·69	0·180	0·306	3·08	5·25
January	1·85	0·178	0·318	3·04	5·39
February	1·03	0·169	0·542	5·62	7·36
March	2·79	0·256	0·607	6·53	10·18
April	1·22	0·169	0·860	5·25	7·50
May	1·55	0·240	0·739	7·40	9·93
June	0·14	0·048	0·140	1·63	1·96

Zirconium-95/Cæsium-137 Ratio in Rain-water

Monthly collections of rain-water from Srinagar for the period October 1958–June 1959 and individual rain samples collected at Bombay during June 1959–September 1959 were analysed for zirconium-95 and cæsium-137 activity using a gamma-ray scintillation spectrometer. The scintillation spectrometer consisted of a 10-channel pulse-height analyser, and a well-type sodium iodide scintillation detector. Each sample was counted several times over a period of 5–6 months, and the 0·75-MeV. gamma-ray peak due to zirconium-95 verified for its 65 days half-life. The activity of each sample was corrected for decay to the middle of the collection period.

Fig. 2 shows the zirconium-95/cæsium-137 ratio for the period October 1958–September 1959 for both Srinagar and Bombay samples. It will be seen that the ratio rises at Srinagar in December 1958. This indicates the increase of fresh nuclear debris in the troposphere, presumably from the October 1958 tests. During December 1958–May 1959 the ratio decreases, and the points lie close to the decay curve of zirconium-95 (half-life 65 days) shown by line *AA*. The observed ratios for June 1959 and subsequent samples show an increasing departure from line *AA*. The departure may be explained as follows.

As will be seen from Fig. 1, the airborne activity which had shown an increase following the October 1958 tests came down to a fairly low level in June 1959. After June 1959 one would therefore expect an increasing proportion of fission products from the earlier equatorial tests, which probably have a larger residence-period in the stratosphere. Thus the ratio zirconium-95/cæsium-137 in the precipitation samples after June would be more dependent on the relative abundance of cæsium-137 from equatorial and polar tests. If we assume that the fall-out from the polar tests in 1958 is superimposed on a constant background of cæsium-137 from earlier tests, and that all the zirconium-95 activity in the atmosphere during June–September 1959 is from October 1958 tests, the departure of zirconium-95/cæsium-137 ratio from the calculated value from June onwards should be due to the rapid depletion of the debris of polar tests in the atmosphere. The residence-time in the atmosphere for the debris from polar tests is estimated from a least-square fit to the points between June and September as shown by line *BB*. The slope of this line gives $(\lambda_R + \lambda_T)$, where λ_R is the radioactive decay constant for zirconium-95 and $\lambda_T = 1/\tau$, where τ is the mean residence-time in the atmosphere for debris from polar tests. The value of τ is calculated from line *BB* to be about 60 days.

Estimates of the External Gamma-radiation Dose

The levels of deposition of (zirconium-95 + niobium-95), (cerium-144 + praseodymium), ruthenium-

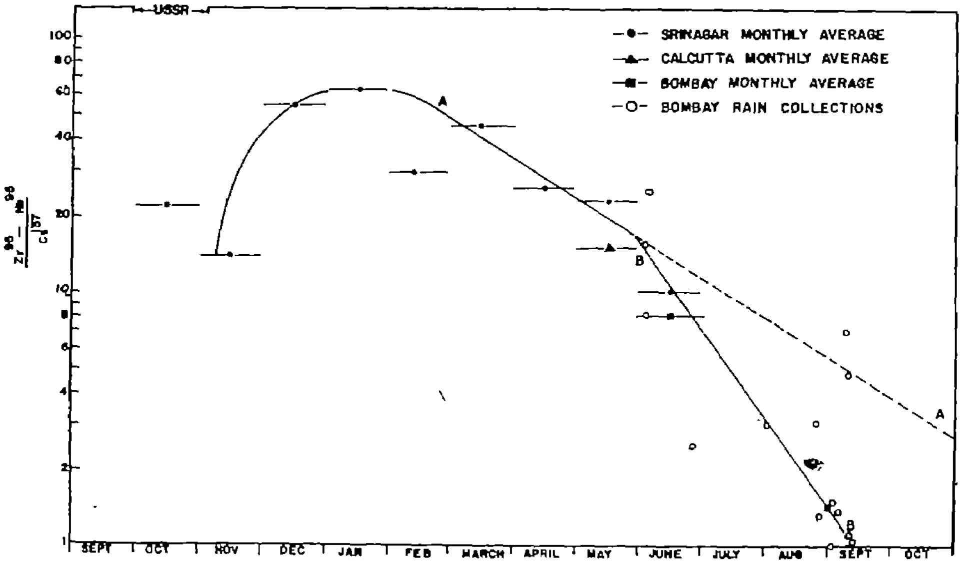

Fig. 2. (Zirconium-95 + niobium-95)/cæsium-137 ratio in rain-water for the period October 1958–September 1959. Line *AA* corresponds to the radioactive decay of zirconium-95, and line *BB* is a least-square fit to the experimental points during June–September 1959

106 and cæsium-137 were measured in the monthly collections of rain-water at Srinagar for the period October 1958–September 1959. The infinity gamma-dose from these isotopes has been estimated for the different months and the results are shown in Table 1. The maximum dose is about 10 m.rems observed in the month of March 1959. The total dose from these isotopes during October 1958–June 1959 is about 50 m.rems. The actual dose will be higher than this, because the contribution from the shorter-lived isotopes has not been considered.

MEMORY EFFECT IN THE THERMAL INITIATION OF EXPLOSIVES

By Dr. WERNER R. HESS and Dr. RUFUS C. LING*

Picatinny Arsenal, Dover, New Jersey

THE 'memory effect' is a quite well-known phenomenon in the thermal sensitization of explosives. It manifests itself through the apparent equality between the time of ignition delay (induction period) of an unsensitized sample and the sum of the durations resulting from several thermal treatments. Thus, Ubbelohde[1] found that the total induction periods of lead azide and mercury fulminate heated at a given temperature T_0 are practically the same whether measured in one or more stages. Multi-stage heating involves heating a sample at T_0 for a time t_1 followed by chilling and repeating this cycle one or more times until an explosion is finally observed. Algebraically, this can be stated by the equation:

$$\tau_0 = t_1 + t_2 + \ldots + \tau \qquad (1)$$

where τ_0 is the one-stage induction period, $t_1, t_2 \ldots$ are the durations of the first, second, etc., heating stages, and τ is the time to explosion associated with the last heating stage. It is experimentally observed that τ_0 is a lower limit for the sum of terms on the right side of equation (1).

Jones and Jackson[2] observed the memory effect in both primary and secondary explosives. These authors presumed this effect to be related to the kinetics of the decomposition reaction, since a shortening of the induction period occurred only where autocatalysis by condensed decomposition products had been definitely established. In this article an attempt is made to explain the effect in terms of equation (1) and a particular autocatalytic reaction equation. Then, the memory effect is seen to depend primarily on the concentration of catalyst formed during the thermal treatment, since the rate of the decomposition reaction naturally increases with increasing initial concentration of catalyst.

Measurements of the induction period as a function of temperature generally follow the Semenov equation:

$$\ln \tau = B + \frac{E}{RT} \qquad (2)$$

which permits one to calculate values for an apparent activation energy E. Theoretical justifications of the validity of equation (2) have been supplied by several authors. For example, from the fundamental thermal theory of explosion by Franck-Kamenetski[3] (which was extended to solids by Rideal and Robertson[4]), Cook[5] derived a relation of the Semenov-type which takes into account both the heat conduction and the geometry of the sample. On the other hand, Eyring and co-workers[6] gave an expression for the induction period by assuming a first-order reaction and neglecting losses of heat by conduction. Then again, Semenov[7] treated self-ignition of gases on the basis of an autocatalytic reaction equation and the influence of heat conduction. Similarly, Andreev[8] showed that a Semenov-type relation for the induction period is obtained when an autocatalytic reaction equation is used as will be discussed later.

The basic problem in any theoretical explanation of the induction period derives from the difficulty of finding a kinetic law which is valid for the reaction under consideration. In the chain theory[9] possible mechanisms for reactions in solids have been described to a large extent. However, in spite of extensive agreement with experiments, the general validity of this theory has not yet been established.

Accordingly, we shall assume the simple autocatalytic reaction:

$$B \xrightarrow{A} A + C \qquad (3)$$

which is governed by the kinetic equation:

$$\frac{dx}{dt} = K_0(a + x)(b - x) \qquad (4)$$

Here, x is the concentration of the reaction product A with its initial concentration a, b is the initial concentration of the substance B, and K_0 is the temperature-dependent reaction-rate constant. Equation (4) enables one to derive the relationship between the amount of catalyst x produced after the time t.

It is known that equation (4) is primarily valid for certain reactions in the gaseous phase or in solutions. However, a number of experimental investigations showed that the simple autocatalytic relation is a sound approximation also in cases concerning condensed systems.

Hinshelwood[10] reported that the decomposition behaviour of molten tetryl satisfies equation (4). Prout and Tompkins[11] described the decomposition of potassium permanganate by an expression similar to the solution of the above autocatalytic law (4) derived from the expanded chain theory. The same relation fitted the decomposition curves of some organic compounds as found by Vaughan and Phillips[12]. In the theory of branching and terminated chains the following equation is derived[13]:

$$\frac{dx}{dt} = K.x.(x_f - x) \qquad (5)$$

---

* Present address: Annandale, Virginia.

which neglects chain interference at $t = 0$, and differs from the autocatalytic law (4) only by the omission of the initial concentration a. This formal identity emphasizes a similarity of the picture of the Brownian movement and collisions in gases to the branching of chains in solids.

It is, however, not necessary that the kinetic law be fulfilled over the total decomposition-range. An agreement is demanded only up to the accelerating region, where slow decomposition changes to explosion. In the beginning of the reaction, the formation of catalyst nuclei takes place and secures a proportionality to the concentration. At a later stage, these nuclei may grow during the reaction, so that a certain amount of catalyst is screened out from further participation in the catalysis. As the reaction proceeds further, a transition to an interface catalysis will occur. When the interface process becomes dominant compared with the 'linear' chain catalysis the diminution of active catalyst may be described approximately by means of exponents :

$$\frac{dx}{dt} = K_0(a + x)^n . (b - x)^m \qquad (6)$$

An equation of this kind has been used already for complicated gas reactions by Semenov[14].

The simple type of reaction equation (4) will, however, be used for mathematical treatment in this work. That means that a duration of the reaction is considered in which the growth of nuclei is negligible compared to the formation of new nuclei. This is justified very well by the chain theory itself, which claims that the reaction in a solid goes on along certain preferred paths. On the other hand, however, this supposition does not affect the autocatalytic view of the reaction. It seems reasonable that decomposition products may catalyse much more easily those neighbours in the lattice which are already in a higher energy stage. (Edge sites are preferred to surface, etc.) An autocatalytic process demands that an initial concentration of catalyst be present to start the reaction. Mathematically, this is reflected in the integrability of equation (4) from $x = 0$, when $a > 0$ is taken. The concentration a may be represented by lattice defects, etc., and will in general depend on the history of the sample. This explanation does not seem sufficient, however, when a assumes values too large relative to the concentration b as shown later. In these cases, one may follow the suggestion of Andreev[15] by superposing a first-order reaction which is responsible for starting the decomposition :

$$\frac{dx}{dt} = k_1 . (b - x) + k_2 . x . (b - x) \qquad (7)$$

It can easily be seen that equation (7) is identical to equation (4), when a is set equal to k_1/k_2.

In all the following calculations, heat conduction losses will be neglected. First, the limiting case is that in which the temperature is considered to be constant. Then, the existence of a true memory effect according to equation (1) can be shown easily. The isothermal solution (K_0 = constant) of equation (4) permits determination of the time t after which any desired amount x of catalyst has been formed :

$$t = \frac{1}{(a + b)K_0} \ln\frac{b(a + x)}{a(b - x)} \qquad (8)$$

The induction period is assumed to be the time at which the maximum reaction velocity is reached, and is determined for the untreated sample as :

$$\tau_0 = \frac{1}{(a + b)K_0} \ln\frac{b}{a} \qquad (9)$$

and for the preheated sample containing an amount of catalyst $(a + x)$ as :

$$\tau = \frac{1}{(a + b)K_0} \ln\frac{b - x}{a + x} \qquad (10)$$

Addition of equations (8) and (9) and comparison with equation (10) proves the existence of equation (1).

The experimental results show, however, that a true memory effect is never exactly achieved and that only the following inequality :

$$\frac{\tau}{\tau_0} > 1 - t \qquad (11)$$

written in relative terms agrees with the observations. Therefore, self-heating will be introduced to improve the description of the effect. The significance of self-heating is evident not only in the thermal theory of initiation of explosions by Franck-Kamenetski[16] (which is concerned with temperature increase in a heated sample), but also by experimental results of Vaughan and Phillips[17] in the case of mercury fulminate.

For practical reasons, the kinetic equation (4) is rewritten in terms of concentrations normalized with respect to the initial concentration b :

$$\frac{dx}{dt} = ke^{-E/RT} . (\alpha_0 + x)(1 - x) \qquad (12)$$

where x is now the relative amount of the reacted material ; k is a proportionality factor which includes the frequency factor ; E and R represent, respectively, the activation energy and the gas constant, and α_0 is the (formal) initial concentration of the catalyst. If α_0 is interpreted as the ratio of the reaction-rate constants according to Andreev[15], α_0 will be dependent on temperature, though of a lower order than k alone. This fact may permit one to consider α_0 approximately constant compared to k.

Again, loss of heat by conduction will be neglected, which is a reasonable assumption when the self-heating is small during the main part of the induction period, as is shown later. The heat of reaction evolved by an exothermic reaction will then be used solely to raise the temperature of the explosive sample. On this basis, the amount reacted x is given by :

$$x = \frac{C_v(T - T_0)}{\Delta H} \qquad (13)$$

where T_0 is the bath or hot-plate temperature, and C_v is a mean specific heat. By introducing a hypothetical temperature T_∞ which is the maximum temperature attainable in an adiabatic reaction, equation (13) can be written :

$$x = \frac{T - T_0}{T_\infty - T_0} \qquad (14)$$

From equations (12) and (14), it follows that :

$$\frac{dT}{dt} = \frac{k . e^{-E/RT}}{T_\infty - T_0} . (T - T_1)(T_\infty - T) \qquad (15)$$

where :

$$T_1 = T_0 - \alpha_0(T_\infty - T_0)$$

Integrating equation (15), one obtains, in terms of the logarithmic integral :

$$t = \frac{1}{(1+\alpha_0)k}\left\{\left(e^{y_1}\int_{{}_1p_0}^{\infty}\frac{e^{-p}}{p}\mathrm{d}p + e^{y_\infty}\int_{-\infty}^{q_0}\frac{e^q}{q}\mathrm{d}q\right) + \right.$$

$$\left. -\left(e^{y_1}\int_{{}_1p}^{\infty}\frac{e^{-p}}{p}\mathrm{d}p + e^{y_\infty}\int_{-\infty}^{q}\frac{e^q}{q}\mathrm{d}q\right)\right\} \qquad (16)$$

where
$y = E/RT$, $y_0 = E/RT_0$, $y_1 = E/RT_1$ $y_\infty = E/RT_\infty$, ${}_1p_0 = y_1 - y_0$, $q_0 = y_0 + y_\infty$, ${}_1p = y_1 - y$, $q = y + y_\infty$.

Fig. 1 shows the temperature-time profile schematically. (The dotted line indicates the above-mentioned influence of loss of heat by conduction.) The steep rise of temperature represents a self-acceleratory reaction leading to ignition, and the time required for this to occur may be defined as the induction period τ_0, characteristic of the sample under study. Such a definition implies that near τ_0 the time is practically independent of the temperature, and consequently that the last two T-dependent terms in equation (16) compensate each other. Then the induction period:

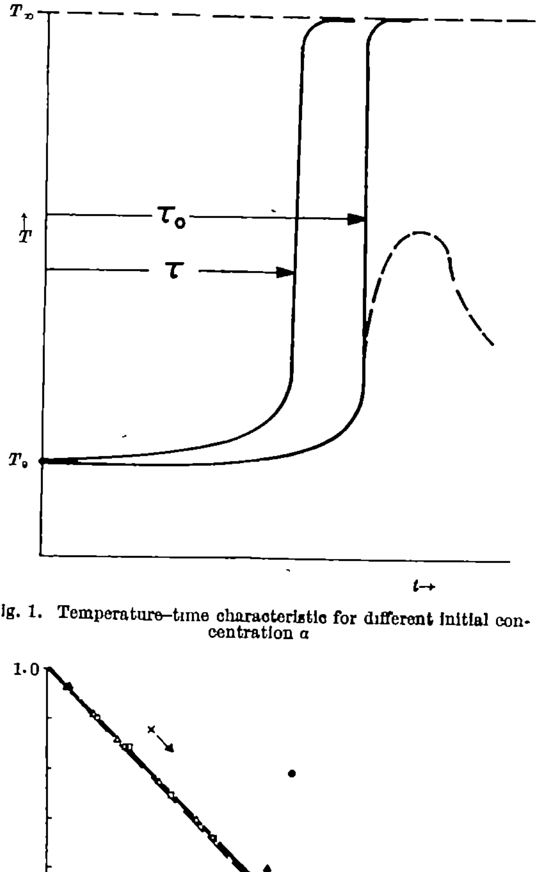

Fig. 1. Temperature–time characteristic for different initial concentration a

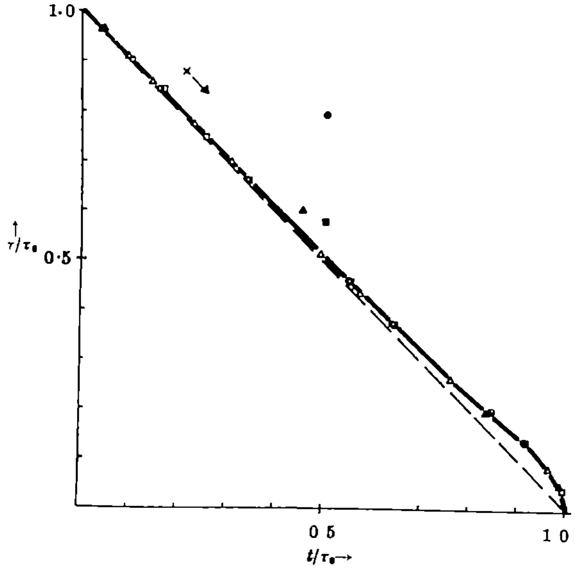

Fig. 2. Calculated pairs of values (τ/τ_0, t/τ_0) for: lead azide, △ : E = 38 kcal./mole, $\Delta H/C_v$ = 8,836° K., T_0 = 603° K.; PETN, ○ : E = 37 kcal./mole, $\Delta H/C_v$ = 5,130° K., T_0 = 521° K.; tetryl, □ : E = 52 kcal./mole, $\Delta H/C_v$ = 4,804° K., T_0 = 525° K.; in all three cases, $\alpha_0 = 10^{-6}$. The solid signs, ▲, ●, ■, represent experimental values

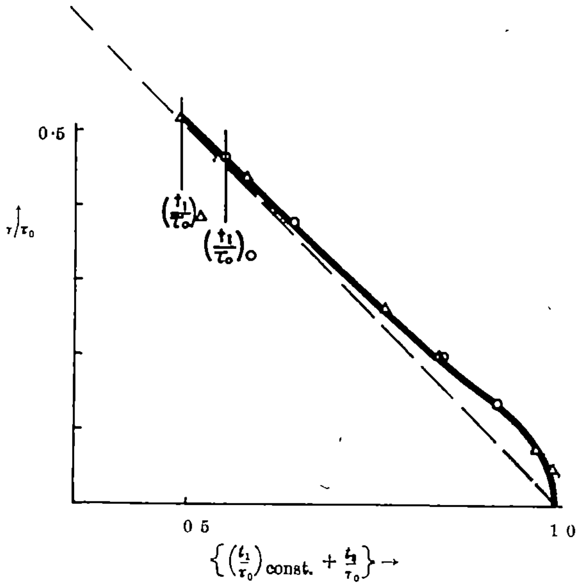

Fig. 3. Calculated pairs of values concerning the preheating times (t_1/τ_0 = const.) for lead azide (△) and PETN (○)

$$\tau_0 = \frac{1}{(1+\alpha_0)k}\left\{e^{y_1}\int_{{}_1p_0}^{\infty}\frac{e^{-p}}{p}\mathrm{d}p + e^{y_\infty}\int_{-\infty}^{q_0}\frac{e^q}{q}\mathrm{d}q\right\} \qquad (17)$$

depends, in essence, only on the initial concentration of the catalyst and the bath temperature T_0. The memory effect is now reduced to a description of the amount of autocatalytic decomposition product formed in a given length of time.

When the autocatalytic reaction is interrupted after a heating time t by cooling the explosive sample, an amount x of the catalyst formed can be calculated by using equation (16) and the relationship between x and T shown in equation (13). When the reaction is resumed by heating to the previous temperature T_0, the initial concentration of catalyst is increased by the amount x to $\alpha_1 = \alpha_0 + x$, and the new, shorter induction time τ can be evaluated by a similar integral:

$$\tau = \frac{1}{(1+\alpha_1)k}\left\{e^{y_2}\int_{{}_2p_0}^{\infty}\frac{e^{-p}}{p}\mathrm{d}p + e^{y_\infty}\int_{-\infty}^{q_0}\frac{e^q}{q}\mathrm{d}q\right\} \qquad (18)$$

where

$$y_2 = E\{R[T_0 - \alpha_1(T_\infty - T_0)]\}^{-1},\ {}_2p_0 = y_2 - y_0.$$

Knowing τ_0, τ, and t from the integrals mentioned, and assuming the constancy of k, one can check the memory effect by plotting τ/τ_0 against t/τ_0. For an exact linear memory effect, a straight line with a negative slope of unity will result. Fig. 2 shows a plot of three examples with known ΔH, E, and C_v. In all cases α_0 is chosen to be relatively small, such as

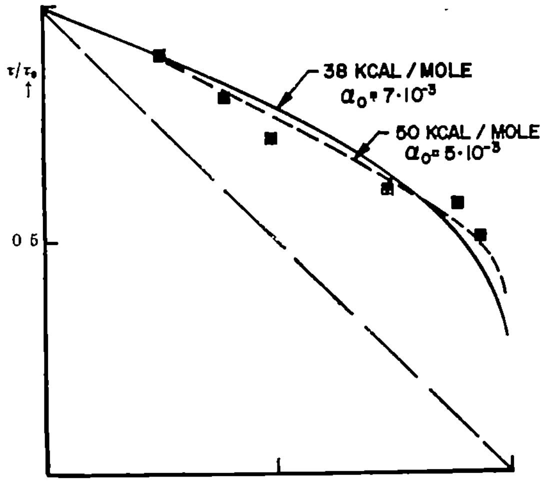

Fig. 4. Thermal sensitization of Service lead azide at 330° C. ■, Experimental values by A. S. Hawkes and C. A. Winkler, and calculated curves

10^{-6}. By this choice, the linear memory effect is still well approximated. Fig. 3 gives a demonstration of a second preheating time which causes scarcely any change of the curve (the heavy line in Fig. 3 is taken from Fig. 2).

As mentioned earlier, the experimental results for the most part do not agree with even a fairly linear relationship as also indicated by a few experimental points in Fig. 2. A theoretical curve which fits these results can be determined by changing the parameter α_0. Fig. 4 shows a comparison of memory effect data by Hawkes and Winkler[18] and two calculated curves at a constant bath temperature of 330° C. for activation energies of 38 kcal./mole and 50 kcal./mole respectively. The test material in these cases was Service lead azide, so the assumed α_0-values of 7×10^{-3} and 5×10^{-3} respectively cannot be said to be characteristic of the pure material. Nevertheless, it seems doubtful that such a relatively high α_0-value can represent lattice effects only. For lead azide, it was observed that the autocatalytic reaction is superposed by a simple, probably first-order reaction[19], in the sense used by Andreev[15]. Thus, even the degenerated, non-linear memory effect can be explained by the model demonstrated.

In summary, the mathematical treatment presented here provides a theoretical explanation of the relationship between the memory effect in an explosive and its autocatalytic decomposition as shown by the validity of equation (1) or the inequality (11), respectively.

We wish to acknowledge the encouragement of Dr. J. V. R. Kaufman.

OCTAHEDRAL CO-ORDINATION OF NICKEL IN NICKEL(II) *BIS*ACETYLACETONE

By Dr. G. J. BULLEN
Department of Physics, Birkbeck College, University of London, W.C.1
AND
Dr. R. MASON and Dr. PETER PAULING
Department of Chemistry, University College, London, W.C.1

DISCUSSION of fourfold co-ordination of the nickel atom in paramagnetic chelate complexes of nickel(II), $Ni(x—x)_2$, where $x—x$ is a bidentate ligand such as a β-diketone or salicylaldehyde, has centred on whether such co-ordination is tetrahedral or square planar. An early suggestion[1] that magnetic data indicated the tetrahedral arrangement was rejected by Calvin and Melchior[2] as inconclusive. More recently, Maki[3] has claimed that no *a priori* correlation between the magnetic moment and structure of these complexes is possible since a molecule having, say, a square planar configuration may be either diamagnetic or paramagnetic depending critically on the strength and symmetry of the ligand field. Maki[4] indeed suggests, on the basis of the ultra-violet absorption spectrum in benzene, that nickel(II) *bis*acetylacetone, often quoted as an example of a tetrahedral complex, has a planar structure. Tetrahedral co-ordination of nickel(II) has been demonstrated for *bis*triphenylmethylarsonium nickel tetrachloride[5].

An early X-ray diffraction analysis[6] of nickel(II) *bis*acetylacetone produced the unexpected result that the molecules are trimeric; a complete solution of the structure was not possible at that time, although it was clear that the nickel atoms in the trimer might well be octahedrally co-ordinated. We now report that the complete analysis of the structure, by Fourier and least-squares methods, confirms this suggestion. The usual discrepancy factor for this kind of analysis:

$$R = \frac{\sum_{hkl} \left| |F_{\text{obs.}}| - |F_{\text{calc.}}| \right|}{\sum_{hkl} |F_{\text{obs.}}|}$$

is 0·14 at the present stage of refinement and corresponds to average estimated standard deviations of 0·015 Å. and 0·05 Å. for the nickel–nickel and nickel–oxygen bond-lengths.

A perspective diagram showing the arrangement of the ligands around the nickel atoms is shown in Fig. 1; bond-lengths and bond-angles are given in Fig. 2.

A distorted octahedral co-ordination of each nickel atom results from the bridging of each pair of nickel atoms by three oxygen atoms. The Ni(1) – Ni(2) and Ni(2) – Ni(3) separations are 2·887 Å. and 2·896 Å. respectively (equal, within experimental error). The bond-angle Ni(1) – Ni(2) – Ni(3) is 179·2° ± 0·7°; the arrangement of the nickel atoms is thus linear.

The molecule as a whole is pseudo-centrosymmetric, the root-mean-square deviation of the lengths of chemically equivalent Ni–O bonds being 0·04 Å. and of equivalent O–Ni–O and Ni–O–Ni bond-angles 3°. Since the environment of the molecule in the crystal is not centrosymmetric, there is little evidence that intermolecular forces play any substantial part in establishing the molecular configuration in the crystal. The Ni–O bond-length appears to depend on whether the oxygen is bonded to only one nickel atom ($\bar{l}_{\text{Ni—O}} = 2{\cdot}00$ Å.) or shared between two nickel atoms ($\bar{l}_{\text{Ni—O}} = 2{\cdot}12$ Å.) (see Fig. 2 for spread of observed bond-lengths).

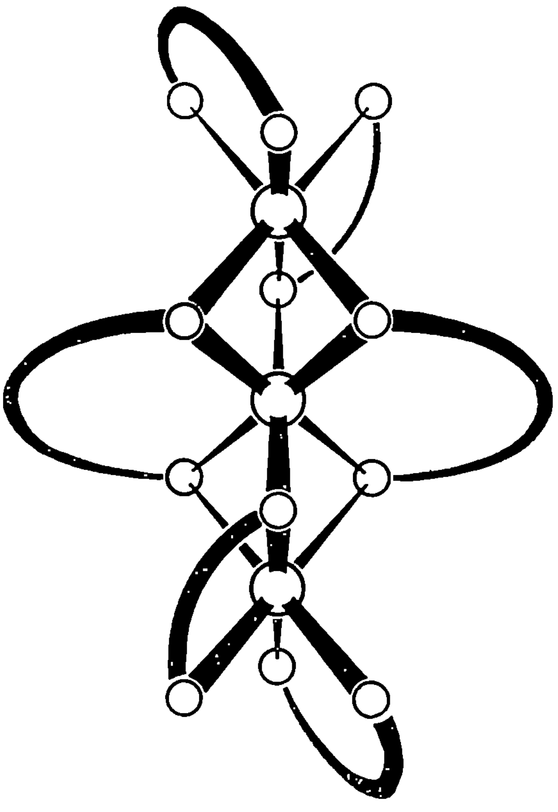

Fig. 1

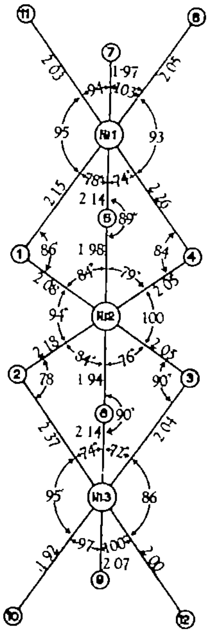

Fig. 2

The trimeric nature of the molecule is understandable in so far as a trimer is the smallest polymeric unit in which octahedral co-ordination of all the nickel atoms can be accomplished, provided there is only intramolecular sharing of oxygen atoms. It seems possible that trimerization occurs with other complexes of this type if the chelate groups are not too bulky for steric hindrance to prevent the association. A recent investigation[7] of single crystals of nickel(II) *bis*salicylaldehyde shows that the monoclinic unit cell contains twelve formula units. Zinc(II) *bis*acetylacetone crystallizes in a similar way with $a = 19{\cdot}2$ Å., $b = 8{\cdot}4$ Å., $c = 24{\cdot}4$ Å., $\beta = 113°$, and with twelve formula units in the unit cell ($\rho_{\text{obs.}} = 1{\cdot}40$ gm. cm.$^{-3}$, $\rho_{\text{calc.}} = 1{\cdot}45$ gm. cm.$^{-3}$). This implies that, as with nickel(II) *bis*acetylacetone, these structures contain trimeric units.

The present confirmation of octahedral co-ordination of the complex in the crystal makes it desirable to re-examine deductions regarding the structure of nickel(II) *bis*acetylacetone in the vapour phase and in solution. Shibata *et al.*[8,9] concluded from electron diffraction studies that the molecule is planar in the vapour phase; the analysis is inconclusive, since the possibility of octahedral co-ordination was not considered. The observed radial distribution curve does not agree well with that calculated on the basis of a planar model, and a rough calculation shows that an octahedral configuration is in reasonable agreement with the data. Isomorphism of nickel(II) *bis*acetylacetone and zinc(II) *bis*acetylacetone was also claimed[10], whereas our single-crystal X-ray studies demonstrate orthorhombic and monoclinic symmetries respectively; the identification of the present crystal structure with a yellow high-temperature modification[6] cannot be valid.

Maki favours a planar structure of the complex in solution[4]; Jørgensen[11] suggests that octahedral co-ordination results from two solvent molecules (benzene) interacting in the *trans* positions. Early molecular weight determinations in benzene made by one of us indicated molecular association; more accurate measurements (F. A. Cotton, private communication) appear consistent with a monomer–trimer equilibrium. We believe that trimerization will occur as a means of achieving octahedral co-ordination, which could also be accomplished through solvent interaction with the monomer or dimer.

The calculations for this work were carried out on the University of London *Mercury* computer. We wish to thank Mr. O. S. Mills and Dr. J. S. Rollett for making their computer programmes available to us.

SEPARATION OF UNIVALENT FRAGMENTS OF RABBIT ANTIBODY BY REDUCTION OF A SINGLE, LABILE DISULPHIDE BOND

By Prof. A. NISONOFF*, G. MARKUS† and F. C. WISSLER

Departments of Biochemistry Research, Biology and Biophysics, Roswell Park Memorial Institute,
Buffalo, 3, New York

PORTER[1,2] has shown that hydrolysis of the rabbit antibody molecule with papain yields three fragments, two of which possess combining sites; the third is inactive but crystallizable. He reported that the molecular weight of the inactive fragment is about 80,000, while that of each active segment is 50,000–55,000. Evidence indicating that the two active fragments are univalent is their capacity to block precipitation in the homologous system; the observation of two chromatographically separable active fragments derived from the originally bivalent molecule[1,2]; and the direct determination of valence by measurement of maximum hapten-binding capacity[3].

It has been found by Nisonoff *et al.*[4,5] that successive treatments of the antibody with pepsin at *p*H 4·8, and one of several disulphide-splitting reagents at *p*H 8, where pepsin is inactive, similarly yield univalent fragments. These split-products exhibit a sedimentation pattern and coefficient (3·5 *S*) almost identical with those of a papain digest[5], and are separated into two active and one inactive fractions on carboxymethylcellulose, under conditions identical with those used by Porter for a papain digest[1]. Proteolysis with pepsin alone causes a reduction in sedimentation coefficient from about 6·5 to 5 *S*, but the product is still bivalent, as indicated by the retention of capacity to precipitate specifically. Subsequent treatment with a reducing agent or cyanide yields fragments with $s \simeq 3{\cdot}5$. Strong evidence indicating that these fragments are univalent is discussed in ref. 5. It was therefore concluded[5] that the transformation from bivalent to univalent antibody was accomplished by the splitting of one or more disulphide bonds.

Since papain, being a sulphydryl enzyme, has always been used in conjunction with a reagent capable of splitting disulphide bonds, it appeared that a similar mechanism may exist in the digestion of rabbit antibody by that enzyme; that is, removal of an inactive fragment by proteolysis, followed by splitting of the bivalent residue through reduction of one or more S—S bonds.

Recently it has been found[6] that the molecular weight of the 5 *S* precipitating fragment formed by the action of pepsin alone is 106,000, while the average molecular weight of the univalent split-products formed by the further action of a disulphide-splitting reagent (2-mercaptoethylamine) is 56,000.

In the present report data are presented indicating that this transformation can be accomplished by reduction of a single, critical disulphide bond. The results further indicate that this bond is exceptionally labile.

Three gm. of a γ-globulin fraction[7] of rabbit anti-ovalbumin was treated with 2 per cent of its own weight of pepsin at *p*H 4·5 in sodium acetate–chloride buffer of ionic strength 0·14. After incubation for 18 hr. at 37°, the mixture was adjusted to *p*H 8 and dialysed against 4 litres of cold saline–borate buffer, *p*H 8, ionic strength 0·16. The major component was isolated by precipitation with sodium sulphate[6]. On examination in the ultracentrifuge a single peak was observed with $s_{20w} = 5{\cdot}1$. The yield of protein was 1·6 gm. or 53 per cent of the weight of γ-globulin initially present. In the procedure the final dialysis was carried out against 0·06 *M* sodium acetate adjusted to *p*H 7 with acetic acid.

Two-ml. aliquots of this preparation, containing 34 mgm. protein per ml., were adjusted to *p*H 5·0 with 2 *M* acetic acid and treated with varying amounts of 2-mercaptoethylamine hydrochloride (MEA) at this *p*H. Each reaction was allowed to proceed for 1 hr. at 37°. At the end of this period 1 ml. of 10 per cent trichloracetic acid was added to each of two 0·5-ml. aliquots taken from a reaction mixture. After standing for approximately ½ hr. each mixture was centrifuged and the precipitate was washed with two 1–2 ml. portions of 5 per cent trichloracetic acid. (It was found that MEA is soluble in 5–10 per cent trichloracetic acid.) The precipitate was then suspended uniformly in 1·2 ml. of saline–borate buffer, *p*H 8, ionic strength 0·16. A 0·1-ml. aliquot was removed for analysis of the protein concentration, and 1 ml. of suspension was dissolved in 30 ml. of the buffer used in the titration of sulphydryl groups[8]. The protein dissolved readily in each case and titrations were carried out immediately. 81–87 per cent of the protein was precipitated by trichloracetic acid in each experiment. More protein was precipitated from the supernatants during the next hour or two, but titrations were carried out early to minimize the possibility of re-oxidation of SH groups. Calculations of the number of SH groups per molecule were based on amounts of protein actually precipitated. As indicated, the procedure yielded duplicate values for the SH content of each sample.

Titration of sulphydryl groups was carried out amperometrically according to the method of Benesch, Lardy and Benesch[8] using 4×10^{-3} *M* silver nitrate. To increase the availability of SH groups a detergent, 0·5 per cent 'Duponol *C*', was added to the titration mixture[9]. In several preliminary experiments it was found that doubling the detergent concentration caused no further increase in the number of titratable SH groups.

A control was run by precipitating the protein with trichloracetic acid without prior treatment with 2-mercaptoethylamine. This was done in triplicate and gave a mean value of 0·75 mole of SH groups per mole of protein (molecular weight

---

* Present address: Department of Microbiology, University of Illinois, Urbana, Illinois.

† Established investigator of the American Heart Association.

106,000), with a mean deviation of 0·09 mole of SH.

For the purpose of testing the effect of reduction on the sedimentation characteristics, aliquots of each mixture, after the reaction with MEA, were quickly cooled to room temperature and treated immediately with enough 1 *M* iodoacetamide to yield a final concentration of 0·04 *M*. In each case this represented an excess in molar concentration over that of the MEA present. The solution was adjusted to *p*H 7·0 and diluted to a protein concentration of 10 mgm./ml. with 0·1 *M* sodium acetate containing sufficient acetic acid to lower its *p*H to 7·0. Samples were then examined in a Spinco model *E* ultracentrifuge at a speed of 59,780 r.p.m. Runs were started within an hour after completion of the reaction with 2-mercaptoethylamine, except in the case noted below, where the effect of standing after treatment with iodoacetamide was tested.

The effect on the sedimentation pattern of a 1-hr. treatment with increasing amounts of MEA is shown in Fig. 1. The s_{20w} values are indicated on the diagrams. With 0·014 *M* or 0·03 *M* MEA the breakdown to $s_{20w} \simeq 3·5$ appeared to be complete. With 0·006 *M* MEA 83 per cent of the protein was broken down, while the transformation reached 66 per cent of completion with 0·004 *M* MEA. The latter run was repeated in the ultracentrifuge after the mixture had been allowed to stand overnight at room temperature. There was no significant change in the pattern (fourth photograph, Fig. 1).

The correlation of these results with the number of new sulphydryl groups formed per molecule is indicated by the graph in Fig. 2. Complete breakdown of the 5 *S* protein was associated with the formation of between 1·7 and 2·9 moles of SH groups per mole of protein of molecular weight 106,000, which corresponds to the splitting of more than 0·85 and less than 1·45 disulphide bonds per molecule.

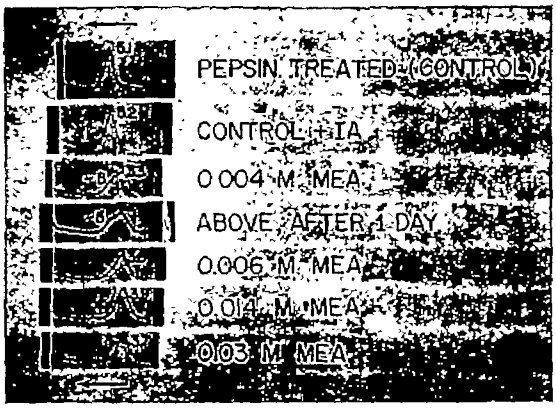

Fig. 1. Effect of 2-mercaptoethylamine hydrochloride (MEA) on the sedimentation characteristics of a purified peptic digest of rabbit antiovalbumin γ-globulin. Photographs taken 67 min after attainment of full speed (59,780 r.p.m.) in the Spinco model *E* ultracentrifuge. The abbreviation IA refers to iodoacetamide. Each sample except the control contained 0·04 *M* iodoacetamide. Each solution also contained 0·1 *M* sodium acetate, adjusted to *p*H 7 with acetic acid. Details of procedures are given in the text The S_{20w} value is indicated near each peak

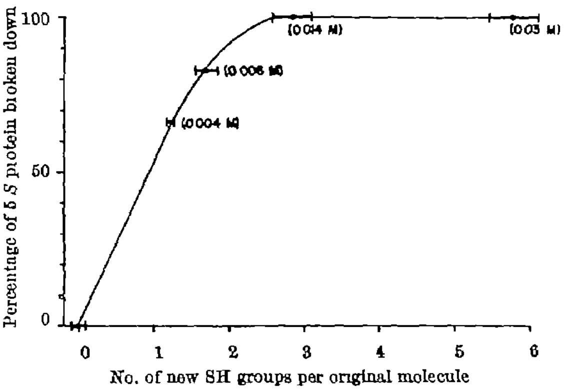

Fig. 2. Effect of 2-mercaptoethylamine hydrochloride (MEA) on a purified peptic digest of rabbit antiovalbumin γ-globulin. The molarity of MEA used is given on the graph. Each reaction was carried out for 1 hr. at 37° as described in the text

It is of interest to compare the fraction of 5 *S* protein broken down with the fraction of a disulphide bond per molecule split, for the experiments in which the breakdown was incomplete. The assumption is made that two new SH groups correspond to the reduction of one disulphide bond. The respective values are 0·66 versus 0·61 (0·004 *M* MEA), and 0·83 versus 0·85 (0·006 *M* MEA). The results indicate that the conversion from a sedimentation coefficient of about 5 *S* to 3·5 *S* is associated with the reduction of a single disulphide bond, and that this bond is exceptionally labile. (If the assumption is made that the 5 *S* protein consists of Porter's fractions I and II, his amino-acid analyses[2] would indicate that there are about 10–12 S—S bonds in the molecule.) Previous measurements of molecular weights further indicate that the molecule is split roughly in half during this conversion[6].

Another characteristic of the conversion is that the molecule loses its capacity to precipitate specifically and acquires the ability to block precipitation in the homologous precipitin reaction[4,5]. There is strong evidence that this is attributable to the univalence of the fragments resulting from treatment with a disulphide-splitting reagent[5]. In the present experiments a portion of each sample tested in the ultracentrifuge was dialysed overnight against 4 litres of the cold saline–borate buffer described above. The protein concentration was adjusted to 8 mgm./ml. and 0·25 ml. portions (2 mgm.) were tested in duplicate for their effect on the precipitation of 1·4 mgm. of untreated antiovalbumin γ-globulin with slightly less than an optimum concentration of ovalbumin, in saline–borate buffer, *p*H 8. Each solution contained 40 μgm. of antigen and the total volume was 0·65 ml. Mixtures were refrigerated for five days. In the absence of fragments, 335 ± 7 μgm. of precipitate was formed. In the presence of the samples treated with 0·006 *M*, 0·014 *M* or 0·03 *M* MEA, no precipitate was formed. The sample treated with 0·004 *M* MEA caused a reduction from 335 to 265 ± 6 μgm. of precipitate. This partial blocking may be ascribed to the fact that the sample was only partially reduced.

None of these preparations caused any significant inhibition in a heterologous reaction, that of bovine γ-globulin reacting with its rabbit antibody to yield 310 μgm. of precipitate. One of the preparations (reduced with 0·006 *M* MEA) caused an increase of 25 per cent in the amount of precipitate formed in the heterologous system. The reason for this apparent enhancement is not known.

None of the MEA-treated samples formed a precipitate when mixed with an amount of antigen that was optimal for the untreated 5 *S* protein, or with one-fourth this quantity of antigen. The limited amount of material available prevented further testing. However, previous work has shown that the 3·5 *S* protein does not form specific precipitates when tested with a wide range of antigen concentrations[8].

In another control experiment it was found that treatment with 0·04 *M* iodoacetamide at *p*H 5, followed by dialysis, had no significant effect on the amount of precipitate formed by a given weight of the pepsin-treated antibody preparation used in these experiments.

There is considerable evidence[5] suggesting that the univalent fragments formed by reduction of the peptic digest of rabbit antibody correspond to Porter's fractions I and II. The present results suggest that these fractions are linked in the antibody molecule by a single, highly reactive disulphide bond. The results do not preclude the possibility that additional bonds, hydrolysed by pepsin, also link these sub-units, or that other, weaker bonds may be involved.

EFFECTS OF ŒSTROGEN ON SOMATIC VARIATION OF AN ERYTHROCYTE AGGLUTINOGEN IN CHICKENS

By S. L. SCHEINBERG and R. RECKEL

U.S. Department of Agriculture, Agricultural Research Service, Beltsville, Maryland

SOMATIC variation of a permanent nature may arise from admixture of erythropoietic tissue during fœtal life[1]. More recently, somatic mutation has been proposed to explain the presence of a low frequency of inagglutinable cells in a population composed predominantly of agglutinable cells[2,3]. Somatic variation may also arise from events of a more transient nature, such as the coating of red cells by plasma as occurs in the '*J*' substance of cattle[4] and the '*R*' substance of sheep[5]. Evidence has been obtained that a hormone also plays a part in somatic variation of a red cell agglutinogen.

A survey of 69 seed extracts which could be used as typing fluids for chicken red cells was carried out with the following results: 64 per cent did not react with the red cells of any of the chickens tested; 9 per cent agglutinated the red cells of all chickens tested; 5 per cent hæmolysed the red cells of all chickens tested and 22 per cent detected differences among individual chickens, 20 or more birds being used in these tests. Among the extracts which could distinguish the cells of individual chickens, those from *Lathyrus cicera*, the falcon pea, and *Pisum arvense*, the Canadian field pea, gave identical reactivities with all birds tested; the substance detected by these extracts was designated 'H_1'. These extracts were found to agglutinate only the red blood cells of females. There were 54 males tested and all were found to be without reactivity; however, the cells of 75 of the 129 females tested were found to be reactive. Reactivity on the red cells was detected when the females reached sexual maturity. Among 7 females tested all became reactive after the onset of egg-laying and maximum macroscopic agglutination scores were reached from 14 to 31 days.

A number of correlative studies (62) were carried out in which chickens were typed monthly or more frequently and the cumulative egg production recorded from one test period until the next. On the basis of these results the hens were placed in three classes; those which were laying or which had laid and whose cells were reactive; those that had never laid and whose cells had never shown reactivity; and the third class consisting of those hens whose cells were non-reactive regardless of the condition of laying. One bird was found the cells of which were reactive but which had not laid any eggs. An autopsy of this bird showed that she was an internal layer, for there were a large number of yolks in the body cavity; therefore, this bird properly belongs in the first category.

Table 1. COMPARISON OF REACTIVITIES OF TERMINAL RED CELLS WITH BONE MARROW CELLS OF NO. *M*5792

	L. cicera		*P. arvense*		Saline or egg albumen	
	Terminal red cells	Bone marrow cells	Terminal red cells	Bone marrow cells	Terminal red cells	Bone marrow cells
11 days after ovariectomy	2–3	(+)	3–4	+	0	0
28 days following ovariectomy	0	—	0	—	0	0
4 days after treatment with diethylstilbœstrol	(+ – 1)	2–3	(+ – 1)	3–4	0	0
	In titrations with *P. arvense*					
	Undiluted	1 2	1 4	1 . 8	1 · 16	1 : 32
11 days after ovariectomy						
Bone marrow cells	+	+	+	(+)	0	0
Terminal red cells	–4	3–4	2–3	2–3	2	0
4 days after treatment with diethylstilbœstrol						
Bone marrow cells	2–3	2–3	2–3	1–2	(1–2)	0
Terminal red cells	(+)	(+)	*	0	0	0

Dashes indicate that tests were not carried out; values in parenthesis are microscopic scores; * refers to a questionable reaction.

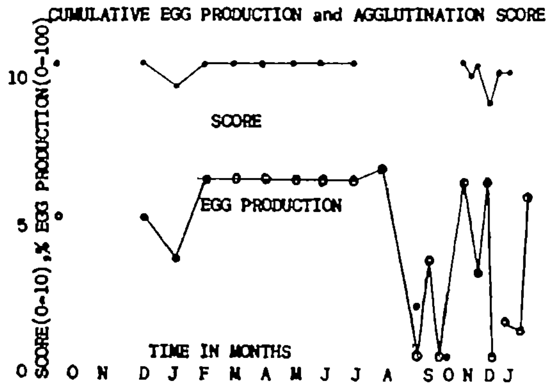

Fig. 1

Fig. 1 presents the results obtained over a period of months with one of the 62 birds under investigation; where the line is not continuous this indicates that information either on agglutination or egg production was not obtained for that date. It is evident that there is a relationship between egg-laying and the presence of the agglutinogen, since the score rises and falls when the egg production rises and falls and remains constant when the egg production is constant. There is a lag, however, between change in score and change in egg production which is most clearly seen for the month of January, when weekly and bi-weekly testing was carried out. A similar lag was observed when birds began egg-laying. The present hypothesis is that the lag was a consequence of transformation to agglutinability which occurs in the bone marrow. Evidence for this hypothesis is presented in Table 1. As expected, under the replacement hypothesis bone marrow was found to be less reactive when the bird was ovariectomized and the terminal red cells were decreasing in reactivity but were still reactive, and, conversely, when the terminal red cells were low in reactivity immediately following the injection of œstrogen, the bone marrow cells were more reactive. Similar experiments have been carried out with other birds, and analogous results were observed in birds beginning to lay or going out of egg production.

The basis for the association between egg-laying and the occurrence of the 'H_i' substance appears to be hormonal. In Fig. 2 it may be seen that the agglutination score decreases to zero following ovariectomy. When injections of diethylstilbœstrol were made, agglutinability increased and when injections of the hormone were discontinued the agglutinability of cells declined. Injection of corn oil (the hormone solvent used) in an ovariectomized bird did not result in a rise in agglutinability, whereas injections of hormones in two other ovariectomized birds gave marked increases in agglutinability as observed with No. *N*5792. All of these results paralleled the increase in agglutinability observed when birds began to lay or were coming back into egg production following a pause.

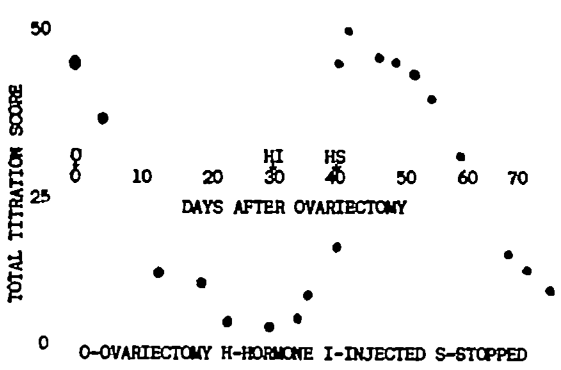

Fig. 2

Preliminary results from pedigree data indicate that the variation observed among the females with respect to the agglutinogen 'H_i' also has a familial basis. Pedigree data were obtained from laying birds the red cells of which were non-reactive and from laying birds the cells of which were reactive. Matings of non-reactive hens from a highly inbred line, from which all the hens tested were non-reactive, gave rise to 29 female progeny, all of which were non-reactive. Four other hens from the same line which were reactive gave rise to 29 female progeny, all of which were non-reactive. Four other hens from the same line which were dead at the time of typing had a total of nine female progeny all of which were non-reactive. The three sires were from lines in which the females were non-reactive and one male was closely related to all the dams. Since it had been shown that diethylstilbœstrol can cause an increase in agglutinability in females which were known reactors, it was of interest to determine whether the presumed genetically non-reactive birds could become reactive if the œstrogen-level were increased. Two females from the non-reactive progeny which were laying were given 16 injections of diethylstilbœstrol, each injection consisting of 0·53 mgm.; a third female, also laying from the same group, was given corn oil. The red cells of these three birds have remained non-reactive during the entire period of testing. These results suggest that there may also be differences in the red cells of the reactive and non-reactive birds not primarily due to the influence of hormone.

Some results were also obtained from test-cross types of matings which demonstrate segregation in the offspring of some reactive hens. Sires were from families in which the female sibs or maternal parent were reactive and such males were mated to non-reactive hens. The reciprocal matings were also made. A total of seven sires were mated to eleven dams and from these matings 12 reactive and 18 non-reactive female progeny were obtained. Results were also obtained from matings (4 sires, 14 dams) in which the hens were not available for typing (they were either dead or had been culled) and the males were from lines in which the hens were reactive. Such matings produced 14 reactive female progeny, 18 non-reactive female progeny and 3 progeny of questionable reactivity.

These observations suggest that the variation observed among the laying hens with respect to the 'H_i' substance is a function of the genotype and a hormonal factor extrinsic to the red cells.

The results presented here will be treated more fully elsewhere. We thank Prof. M. R. Irwin for suggestions in the preparation of this communication.

PHYSICS

Space-Charge Currents in Gallium Arsenide

Mott and Gurney[1] pointed out that an insulator should be able to carry an electronic current if electrons were injected into it by a suitable contact. Such currents were observed experimentally by Smith and Rose[2] in cadmium sulphide crystals. They showed that an essential condition was that the 'deep trap' density should be low, deep traps being centres with energy-levels well below the conduction band which can accept electrons. In a recent communication[3] a model was proposed to account for the properties of semi-insulating gallium arsenide. The model suggested that in this material the above condition should be satisfied, and as a result it was predicted that space-charge currents should be observable. Here we present experimental results confirming the correctness of the prediction.

Wafers of semi-insulating gallium arsenide were prepared from bulk ingots by cutting, grinding and etching. Typical dimensions were 3 × 3 × 0·15 mm. Tin contacts of 0·5 mm. diameter were alloyed at the centres of the two large faces. This configuration makes any surface leakage paths between contacts long. A current-voltage plot taken under d.c. conditions at room temperature for one such specimen is shown in Fig. 1. In the region in which current increases rapidly there were some changes with time, and Fig. 1 shows steady-state values.

Lampert[4] has given the theory for space-charge currents when a single trap-level is present, and we may readily adapt his theory to our model for gallium arsenide. At low voltages any injected charge is trapped, and to a good approximation Ohm's law is obeyed. At high voltages space-charge due to traps is small compared with that due to injected carriers and the variation of current with voltage is given by the solid-state analogue of Child's law[1]:

$$I = \frac{9}{32\pi}\frac{\varkappa\mu V^2}{L^3} \qquad (1)$$

The ohmic and space-charge regions are connected by a region in which the current increases by several orders of magnitude for a small change of voltage. The voltage at which this occurs, called by Lampert the 'traps-filled-limit' voltage, is just the change in potential produced by the space-charge of the filled traps, that is:

$$V_{TFL} = \frac{2\pi e}{\varkappa}L^2(N_A - N_D) \qquad (2)$$

For the specimen the characteristic of which is shown in Fig. 1 the magnitude of the space-charge current agrees with that given by equation 1 within a factor three, which is within the limits of experimental error. Since in this case the thickness L was 0·12 mm., the unfilled trap density $N_A - N_D$ is found from equation 2 to be 8×10^{10} cm.$^{-3}$.

For another specimen from a different ingot the value V_{TFL} was measured and found to be 60 V. Mr. N. A. C. Thompson, of this Laboratory, has measured the resistivity and Hall effect as a function of temperature for specimens cut from the same ingot. From equation 2 we determine $N_A - N_D$ at room temperature to be $3 \cdot 8 \times 10^{12}$ cm.$^{-3}$. Applying the analysis of ref. 3 to Mr. Thompson's measurements, we find $\chi - 1$, which measures the proportional departure from exact compensation, to be 5×10^{-6}. Now:

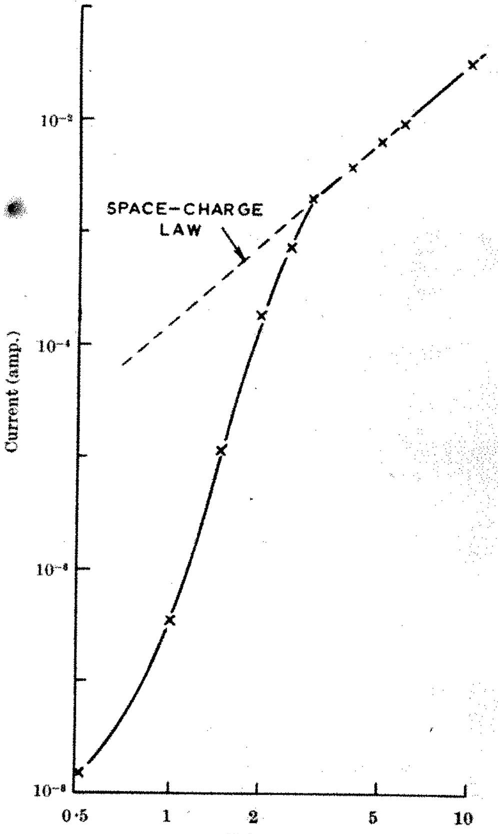

Fig. 1. Current-voltage curve for gallium arsenide showing ohmic and space-charge regions

$$N_D = \frac{N_A - N_D}{\chi - 1} \qquad (3)$$

so by combining space-charge and Hall effect measurements we find N_D, which for this particular specimen turns out to be 8×10^{17} cm.$^{-3}$, a rather high value but not improbably high.

Thus a model in which acceptors at a level deep in the energy-gap are auto-compensated by shallow donors seems a reasonable first approximation in explaining not only the Hall effect but also the space-charge currents in semi-insulating gallium arsenide. It would be interesting to know if a similar mechanism could explain the low trap density observed in cadmium sulphide, but the relevant measurements of carrier concentration as a function of temperature do not seem to be available.

We wish to express our thanks to Mr. N. A. C. Thompson for the use of his experimental results. Acknowledgment is made to the Admiralty for permission to publish this communication.

Hyperfine Splitting of Rubidium-87

RUBIDIUM has been used in the development of gas cell frequency standards, and from measurements of the variation of frequency with the pressure of the buffer gas used in the cell it has been deduced[1] that the frequency corresponding to zero gas pressure is :

6 834 682 608 c./s. ± 7 c./s.

where the second of time is that giving 9 192 631 770 c./s. for the cæsium hyperfine structure splitting at zero field[2]. It has been found, however, that when cæsium is used in a gas cell the extrapolated frequency is 30 c./s. lower than the value given above obtained by an atomic beam experiment[3]. There is therefore considerable interest in the atomic beam value for rubidium. For this purpose the oven of the long beam chamber[4] at the National Physical Laboratory was filled with a mixture of rubidium-87 and cæsium-133. A strong beam of atoms was obtained at an oven temperature of 120° C., and the application of the appropriate radio frequency produced, alternatively, resonances of the rubidium or cæsium atoms. The amplitude of the cæsium resonance was 50 per cent greater than that of rubidium, the higher vapour pressure of cæsium presumably compensating for the fact that a greater proportion of the rubidium atoms take part in the resonance. In both cases the signal to noise ratio was adequate for the precise measurement of the frequencies corresponding to the resonance peaks. The rubidium resonance, which was 71 c./s. wide, was excited in cavities independently tuned and separated by a distance of 254 cm. It was slightly asymmetrical, but the asymmetry was measured and a correction applied. The value on the atomic time-scale corrected for the asymmetry and magnetic field is :

6 834 682 614·0 ± 1 c./s.

It is proposed to continue measurements of the two atomic transition frequencies.

Whisker Growth from Quartz

WHISKER growth and associated phenomena have been extensively reviewed recently by Messrs. N. F. R. Nabarro and P. J. Jackson[1]. They cited observations of growth from metallic oxides, sulphides and hydroxides along with the more usual growth in metals. Whisker growth from fused quartz, apparently an unreported phenomenon, is unusual due to the vitreous nature of the substrate.

The whiskers are shown in Fig. 1. Large single whiskers and clusters of shorter ones grew from discrete places on the substrate. The quartz was heated in a 'Zirco' tube through which flowed 1 litre/min. of dry nitrogen. The temperature was approximately 1,425° C. and time for the growth was 24 hr. Immediately adjacent to the whiskers was a dense patch of pine tree-like dendrites. The whiskers ranged in length from millimetre to micron size.

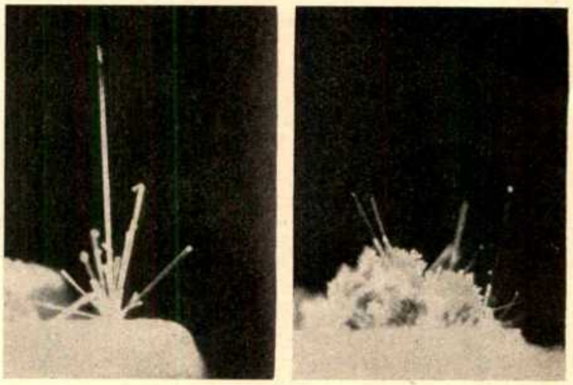

Fig. 1. Quartz whiskers. (× 15)

The quartz substrate from which these whiskers grew had a skin of devitrified quartz covering its surface due to regular use at elevated temperatures. There was silicon material placed on the substrate near the growth area. There is no apparent evidence to point to how the whiskers grew either from the base or at the tip. However, the devitrified skin afforded the conditions for nucleation.

Further work and mechanical tests will be undertaken on these whiskers.

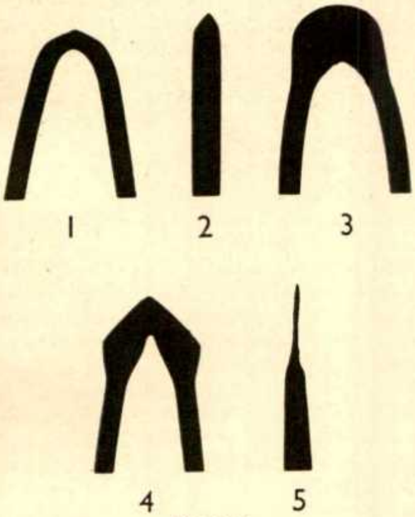
Simple Methods for preparing Pointed Filaments for the Electron Microscope

THE performance of electron guns used in the electron microscope has been studied by Haine and Einstein[1], Boersch and Born[2], and others. The present indications are that pointed filaments improve this performance. The first of these filaments was prepared by Hibi[3] by hand-polishing or etching a short length of tungsten wire which was welded or otherwise attached to a conventional hairpin filament according to Müller's method[4]. Heating was obtained by conduction from the hairpin.

The main disadvantage of the Hibi filament is that it is difficult to prepare and much may depend on the skill of the operator. The present communication describes a very simple method by which pointed filaments may be quickly prepared by any operator.

The basis of the method is to make a point on a conventional hairpin filament. This may be achieved in two ways, either by straightforward grinding or by pinching to make the filament thinner at the tip, followed by grinding. Details of the methods are as follows:

(1) A small disk of fine emery paper (grade 'Corosil' 600 or 000), about 3 cm. in diameter, is stuck to a metal disk and fitted to an electric motor which can revolve at 1,000–3,000 r.p.m. Four flats are ground, according to Figs. 1 and 2. The angles are not critical but should be about 120° in the front view (Fig. 1) and 70° in the side view (Fig. 2). Grinding is facilitated if a low-power lens is used and the following sequence is adopted: (*a*) Grind the faces in Fig. 1 so that a sharp point is obtained. Material is removed rapidly in this case. (*b*) Grind the faces in Fig. 2. More time is required to produce a point in this case. (*c*) Inspect under a × 10 lens, and if the point appears blunt from the front (Fig. 1) touch the faces on the revolving disk for a very short time. (*d*) Inspect the filament from the side (Fig. 2) and if this point appears blunt regrind very lightly.



Figs. 1–5

With a little practice a sharp point can be obtained in about 2 min. Care must be taken not to grind away more than half the diameter of the wire or premature burn-out will occur. This type of filament will be referred to as a ground filament.

(2) A much sharper point can be obtained by pinching a filament (not pre-heated *in vacuo*) at the tip before grinding, using a pair of smooth-faced pliers; the filament tip is inserted so that only about 0·5 mm. is gripped by the pliers. After exerting a sufficiently high pressure the tip will be plastically deformed to the shape shown in Figs. 3 and 5, the latter showing that it is in the form of a thin foil. Before removing the filament from the pliers it is desirable to ensure that the deformed tip has not been bent over, otherwise it must be straightened. It is important that the pliers should be properly hardened, otherwise the tip will not be flattened sufficiently.

Grinding is carried out with the same assembly as before, but it is desirable to use a finer grade of emery paper. A suitable sequence is as follows: (*a*) Touch the foil faces against the rotating wheel to produce the fine point shown in Fig. 5. (*b*) Grind a point subtending an angle of about 90° on the foil periphery (Fig. 4). (*c*) If the point shown in Fig. 5 has become blunt on inspection with a × 10 lens, regrind very lightly. (*d*) Retouch the other two faces if necessary.

The process can be carried out in 2 or 3 min., as the grinding is easier to carry out than in the first method. These filaments will be referred to as pinched filaments.

Consideration of the following general points may help to ensure satisfactory results: The lens used to view the grinding wheel must provide a magnification of about × 5. A telescope is satisfactory, provided that the image is not inverted, otherwise the handling of the filament becomes very difficult. The use of a rheostat to vary the motor speed is valuable if there is a tendency to grind away too much material from the tip. If a large number of filaments are to be made, it may be convenient to make up a simple jig with a swinging arm to hold the filament. Mounting the filament in a metal block will facilitate handling and improve grinding accuracy if a jig is not to be used. Filaments with a sharp bend at the tip give best results.

It is obvious that there is little flexibility in the way a filament can be ground, except perhaps in the case of the pinched type. Here some variation of angle

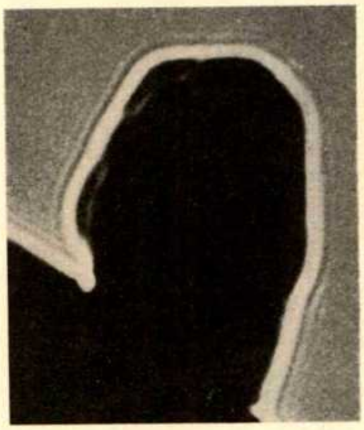


Fig. 6

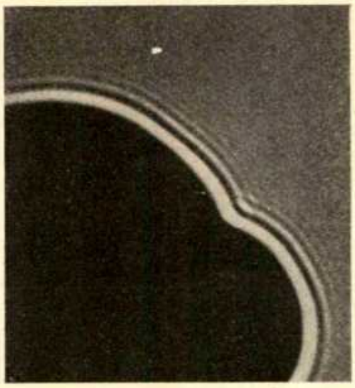

Fig. 7

and amount of material removed can be achieved, though generally with little effect on performance.

Before use, both types of filament should be heated to 2,500° C. *in vacuo*. It is, of course, very important that nothing should be allowed to touch the point, otherwise it will be damaged and the efficiency of the filament impaired.

The centring of the Hibi type of filament is critical, and this is also the case with ground and pinched filaments. All filaments have a tendency to move to a certain extent so that, particularly during the first few minutes of operation, it will be found that the electron gun requires frequent re-alignment. Some trouble can be saved by turning both filament and H.T. supplies on for a few minutes before operation ; this will give the filament a chance to settle into a stable position.

The Hibi filament provides increased coherence in the electron beam, which is also the case with ground and pinched filaments. This is demonstrated by Figs. 6 and 7, which are electron micrographs (×180,000) of under-focused Fresnel fringes taken with standard and pinched filaments respectively. Both condenser lenses were switched off for these experiments in order to have easily reproducible illumination conditions. On the original prints, three fringes were visible with the standard filament, and five with the ground and pinched types.

The increased brightness may be due to either an increased source temperature or to a reduction in space-charge effects on the emission. The temperatures of these pointed filaments have not yet been measured so that a full explanation cannot be attempted. In general, qualitative observations agree with the detailed results of Swift and Nixon[5].

I am grateful to Mr. T. Mulvey for valuable help and discussion, and also to Dr. T. E. Allibone, director of the Laboratory, for permission to publish this communication.

METALLURGY

Production and Mobility of Point Defects in Titanium and Zirconium

ELECTRICAL resistivity measurements have been made by many workers on quenched, irradiated or plastically deformed metals, in order to study the production of defects by these various treatments. By observing the recovery of the resistivity on annealing, it is possible to study the mobility of the various defects out of the material or to internal sinks. In this communication we present some results on the mobility of defects, introduced by low-temperature plastic deformation in titanium and zirconium.

Polycrystalline titanium and zirconium wires (of a purity of about 99·9 weight per cent), were strained in tension at 78° K., and the extra resistivity introduced by the plastic strain was measured at the test temperature as a function of the strain. The increase in resistivity expressed as a percentage of the original resistivity at 78° K. was approximately 8 per cent for titanium and 5 per cent for zirconium, both due to a tensile strain of 6 per cent. Strained wires were then annealed for 15 min. at 78° K., 195° K. and room temperature, the resistivities after each anneal being measured at 78° K. After the room-temperature anneal, more than 50 per cent of the extra resistivity introduced by the plastic deformation was annealed out in the case of titanium, whereas the corresponding value for zirconium was 30 per cent. These recoveries of resistivity showed that there was appreciable mobility of defects below room temperature, these having been produced by plastic deformation. In the case of zirconium, such mobility has been observed previously for defects produced by irradiation ; for Zartman[1] has bombarded zirconium with deuterons at 170° K. and observed a 60 per cent recovery of electrical resistivity on annealing at room temperature.

A very surprising feature of this work was that, for titanium, the resistivity was in fact recovering at the temperature of deformation, 78° K. This effect was not observed in zirconium, but we believed that in this case the recovery might occur too rapidly to be detected by annealing tests at the temperature of deformation.

To test this possibility, wires of both titanium and zirconium were strained in tension at 20° K., and the extra resistivity introduced by the plastic strain was measured at 20° K. as a function of the strain. The increase in resistivity expressed as a percentage of the original resistivity at 20° K. was approximately 30 per cent for titanium and 60 per cent for zirconium, both due to a tensile strain of 6 per cent. The wires were then annealed for 15 min. at 20° K., 78° K. and room temperature, the resistivities after each anneal being measured at 20° K. It was observed, both for titanium and zirconium, that whereas there was apparently no recovery at 20° K., approximately 20 per cent of the resistivity introduced by the 20° K. deformation was recovered after the 78° K. anneal.

This recovery, at temperatures below 78° K., of resistivity introduced by plastic deformation in the hexagonal metals titanium and zirconium, is in marked contrast to the behaviour of the face-centred-cubic metals, copper, nickel and gold, where there is essentially no recovery of resistivity after plastic deformation at low temperatures[2]. In these metals, recovery of resistivity below 78° K. is only observed after very heavy deformation, when some slight recovery does occur in the temperature interval up to 78° K., the recoverable fraction of the resistivity increasing with increasing strain. Of course, there is substantial annealing in the face-centred-cubic metals below 78° K. (the so-called stage I), when the damage giving rise to the resistivity is caused by irradiation with electrons, deuterons or neutrons[3].

Although it may not be altogether valid to compare energies for the movement of various defects in the hexagonal and face-centred-cubic structures, or to compare the temperature ranges in which they move, it is interesting to speculate why there is a difference between the two structures. It would seem that, in our experiments, isolated interstitial metal atoms are produced by plastic deformation, and that these then migrate at the low temperatures involved; whereas in the case of the face-centred-cubic metals the experimental evidence indicates that they are not produced[4]. This difference might be related to a difference in stacking fault energies, for in the hexagonal case where slip occurs mainly on the $\{10\bar{1}0\}$ prism planes, the dislocations should have a relatively high stacking-fault energy, probably much higher than copper, nickel or gold. Support for this idea is provided by the results obtained for aluminium[5], a face-centred-cubic metal with a very high stacking-fault energy; for Sosin and Koehler have found that if aluminium single crystals are deformed in tension to an elongation of 15 per cent at 4° K., then there is a 10 per cent recovery of resistivity on annealing at 78° K. One would expect the effect to be much greater for poly-crystals, where the operation of intersecting slip systems can cause increased production of point defects.

Initiation of Fatigue Cracks in Beta-Brass

FATIGUE cracks have been seen to be initiated in slip bands, twin boundaries and grain boundaries, in a number of investigations on the fatigue behaviour of metals[1-3].

During recent work on the fatigue behaviour of beta-brass a different mode of fatigue crack initiation has been observed, which has not been reported previously in the literature. Certainly, it does not occur in the case of fatigued copper.

Beta-brass was chosen because of the lack of knowledge of the fatigued behaviour of body-centred cubic metals. Polycrystalline material, with an average grain-size of 2 mm., has been fatigued in reverse plane bending at a frequency of 8,400 c./min. Specimens in the form of cantilevers were mechanically polished with care and finally electro-polished prior to fatiguing.

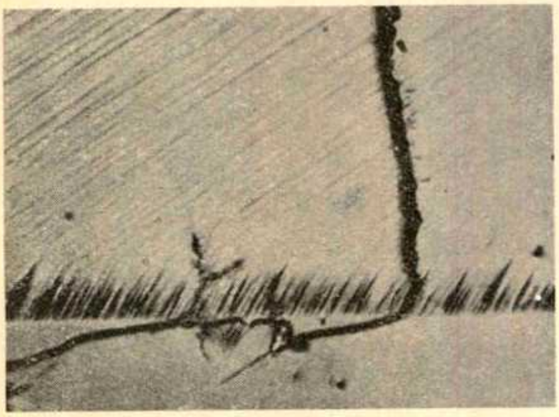

Fig. 1. Surface of fatigued beta-brass specimen. Fatigue cracks initiated in short slip markings adjacent to one side of a grain boundary. Oblique light. (× c. 1,860)

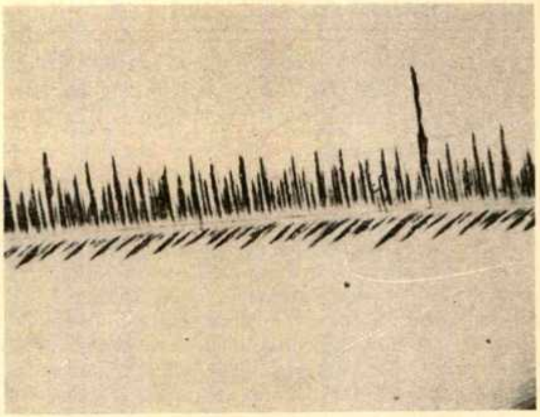

Fig. 2. Surface of fatigued beta-brass specimen. Extrusions on short slip markings adjacent to both sides of a grain boundary. (× c. 1,070)

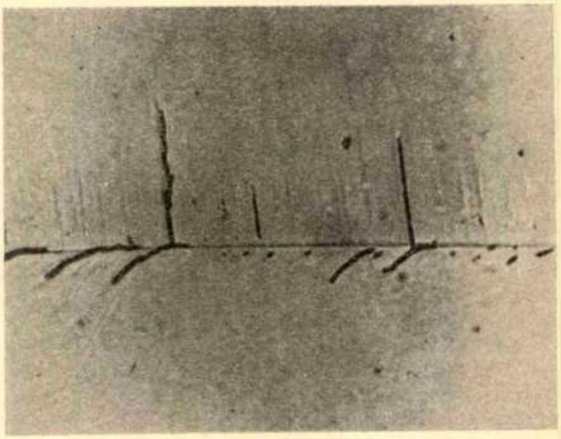

Fig. 3. Surface of fatigued beta-brass specimen. The same area as shown in Fig. 2 after extrusions and slip removed by electro-polishing. Persistent markings, that is, incipient cracks. (× c. 1,070)

One of the main observations has been the initiation of fatigue cracks and the formation of extrusions in short-slip markings, which form adjacent to grain boundaries, and in the majority of cases at an angle to the main slip. These cracks are afterwards propagated into and across the grain boundaries and frequently become linked together.

The most unusual features of this phenomenon are that these cracks form at an angle to the main slip but not in the main slip, and that they form adjacent to the grain boundaries but not in the grain boundaries (Figs. 1, 2 and 3).

Further work leading to a model for the mechanism is in progress.

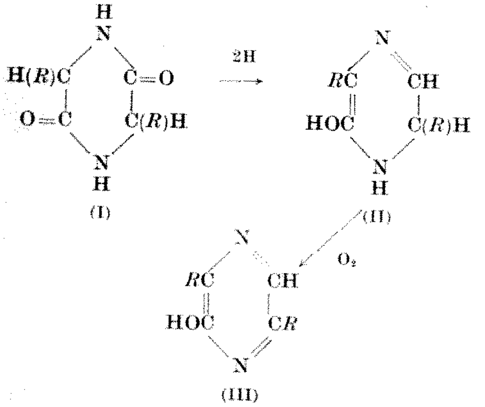
RADIATION CHEMISTRY

Production of Pyrazine Derivatives in the Radiolysis of Aqueous Solutions of the Cyclic Dipeptides

Radiation-induced reactions in aqueous solutions of amino-acids, peptides, and related compounds have been treated in a number of reports from this Laboratory[1]. In connexion with this work, we have had occasion to examine the effects of γ-irradiation on the ultra-violet absorption spectra of solutions of various simple peptides. The measurements reveal that solutions of the cyclic dipeptides under specific conditions exhibit pronounced and characteristic post-irradiation changes. If, for example, an oxygen-free solution of alanine anhydride is irradiated and examined spectrophotometrically, the differential spectrum (read against unirradiated solution) shows negligible absorption above 2600 Å. so long as the solution is not exposed to the atmosphere. However, if oxygen is introduced, an absorption maximum in the longer wave-length region slowly appears. This post-irradiation change is accelerated by addition of either acid or base. In neutral and basic solution the absorption maximum is at about 320 mμ; in acid solution the maximum shifts to 340 mμ. This shift is reversible, and the evidence is that the final yield of the absorbing species is essentially independent of the *p*H of the solution during the post-irradiation oxidation. Solutions of glycine anhydride exhibit quite similar properties except that the wave-length of maximum absorption (320 mμ) is independent of *p*H. It is also to be noted that these post-irradiation changes are not observed if oxygen is present during irradiation.

We believe the phenomenon involves the radiation-induced reduction (and subsequent dehydration) of the diketopiperazine molecule (I) to the corresponding 1 : 2-dihydropyrazine derivative (II) which is of a class of compounds known[2] to be readily oxidized (that is, in air) to the corresponding pyrazine structure (III)



Isolation of 2-hydroxy-3 : 6-dimethylpyrazine (III) from an irradiated solution of alanine anhydride (Nutritional Biochemicals Corporation, Lot 2104, recrystallized three times from water) has been effected. The irradiated solution was lyophilized, and an appropriate aliquot of a methanolic solution of the residue was transferred to a filter-paper strip, and then chromatographed in a butanol–ammonia solvent system[3]. At low radiation dosages a single fluorescent compound ($R_F \sim 0{\cdot}7$) was observed. This was eluted and compared spectrophotometrically with authentic material prepared according to the method of Baxter and Spring[4]. Fig. 1 shows a normalized plot of the results. Co-chromatographic studies of the authentic material and the isolated irradiation product fully support the identification. The initial yield of 2-hydroxy-3 : 6-dimethylpyrazine in 0·1 *M* alanine anhydride corresponds to a *G*-value of $\sim 0{\cdot}4$ (cobalt-60 γ-rays; 7×10^{19} eV./ml.).

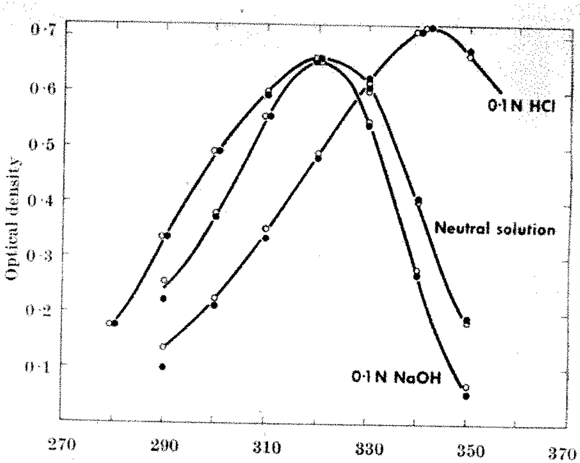


Fig. 1. Absorption spectra of authentic 2-hydroxy-3 : 6-di-methylpyrazine (○) and of product isolated from irradiated solutions of alanine anhydride (●)

This work was performed under the auspices of the U.S. Atomic Energy Commission.

CHEMISTRY

Porous Glass Chromatography

Chromatographic separations have now been achieved using porous glass[1] as a medium. Its extreme inertness, optical transparency, and small pore diameter (about 4 mμ) suggested this usage. Initial results strongly indicate that unusually fine chromatograms can be obtained with this material. Other than in the choice of medium, there is little difference between the techniques described here and those commonly used in paper chromatography.

The present investigation has been concerned with the characterization of fountain-pen inks. The procedure is quite simple, consisting essentially of four steps. First, a 2-μl. sample of ink is placed about one-half of an inch from the edge of a small (3 in. × 3 in.) piece of porous glass. Secondly, the glass is exposed to the vapours of the liquid solvent to be used for development for 1 hr. Thirdly, the sample edge of the glass is dipped into the solvent almost up to the spot of ink and held in this position

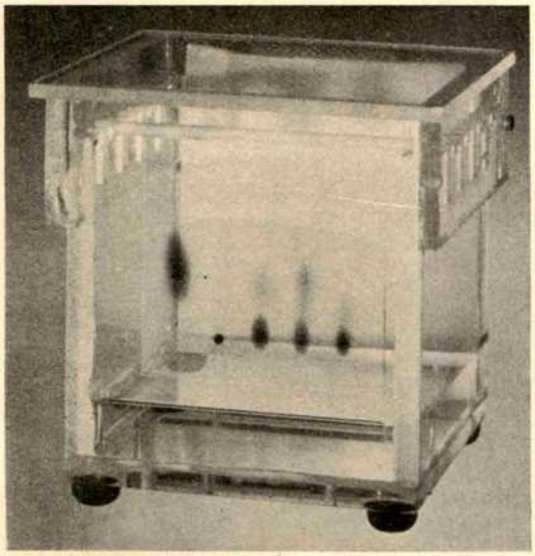

Fig. 1. Chromatographic cell

for about 24 hr. as shown in Fig. 1. Fourthly, and lastly, the glass is removed, wiped dry with a soft cloth, and placed in a warm place to remove completely the absorbed moisture.

Chromatograms resulting from this procedure have yielded excellent separation of the individual constituents depending on their relative solubilities, molecular size and shape, and relative retardation effect to the porous medium. Examples of chromatograms of five ink samples are illustrated in Fig. 2.

Unfortunately, a black-and-white reproduction of these porous glass chromatograms does not do justice to the colourful results which were actually obtained. Sample No. 41, for example, Carter's 986 black ink, resulted in a blue spot where the original sample was placed, a deep green over this, followed by orange and finally a rose or violet on top.

The other inks shown in Fig. 2 are identified: No. 38, Waterman's new permanent black; No. 39, Waterman's old permanent black; No. 42, Higgin's No. 812 eternal permanent black; No. 50, Carter's No. 99 permanent black.

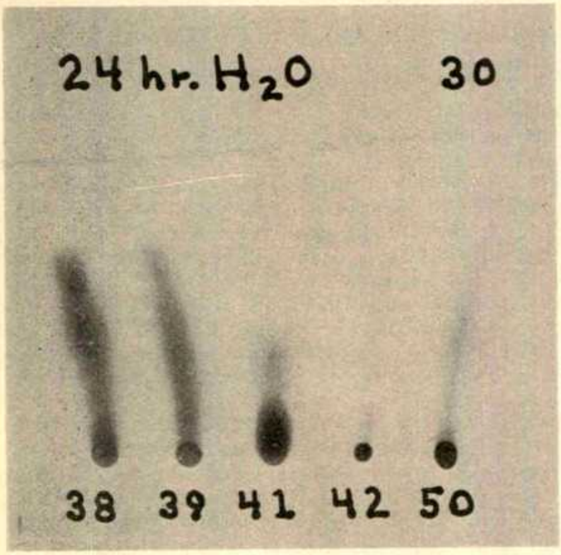

Fig. 2. Porous glass chromatogram

There are several advantages in the use of porous glass as compared to conventional paper for a chromatographic medium. Very high surface area of porous glass (about 150–200 m.^{2} per gm.) confines the sample to a small area due to immediate drying. This, in addition to longer development time, provides improved resolution or definition of the bands. Porous glass can be used with nearly all solvents except hydrofluoric acid and strong alkaline solutions. Being an inorganic inert material, organic contamination is at a minimum and pyrolysis rates of specific components have been observed as individual bands changing in appearance. Porous glass chromatograms can be permanently filed for reference. Optical measurements, including transmission, reflectance and fluorescence, have been made directly on the dry, transparent porous glass after the chromatographic separations have been accomplished.

The original interest in the use of porous glass as a chromatographic medium has been a result of my interest and activity in the field of criminology. It must be pointed out, however, that this medium is not in any way limited to the characterization of fountain-pen inks. The separations and/or purification of body fluids, virus, bacteria and other serological fluids which may be obtained due to their actual molecular dimensions must be investigated. Observations have been made which establish the fact that certain molecules are too large to pass through the small holes in porous glass. Finally, the use of this medium as a support for electrophoretic separations offers possibilities as yet unexplored.

Two New Amino-Sugars from an Antigenic Polysaccharide of *Pneumococcus*

THOUGH a large number of antigenic capsular polysaccharides of *Pneumococcus* are known to contain one or more amino-sugars[1], in only one case, namely, 2-amino-2-deoxy-D-glucose (D-glucosamine) from type XIV polysaccharide[2], has the amino-sugar been isolated and characterized. Two amino-sugars, designated 'pneumosamine' and 'amino-sugar X', have been isolated from purified Type V *Pneumococcus* capsular polysaccharide[3], and preliminary investigations, which included analysis of the crystalline *N*-acetamido alcohol derivatives, indicated that both sugars were 2-amino-2,6-dideoxyhexoses. Kuhn-Roth determinations on '*N*-acetylpneumosaminol' (1·52 moles CH_3) and on 'amino-sugar X' (0·68 mole CH_3) support the postulated 6-deoxyhexosamine structure. The sugars have now been tentatively identified as 2-amino-2,6-dideoxytalose (pneumosamine) and 2-amino-2,6-dideoxy-L-galactose (amino-sugar X). The sugars were isolated from a polysaccharide hydrolysate (hydrolysis conditions: 2 *N* hydrochloric acid, 24 hr., 100°) by chromatography on 'Dowex-50' resin[4]. The acidic effluents were neutralized with 'Deacidite *FF*' (carbonate form), lyophilized and the syrupy residues dried *in vacuo* over phosphorus pentoxide. Treatment of the 'pneumosamine' residue with methanol gave 'pneumosamine hydrochloride' melting point 162–3° (from methanol–ether); $[\alpha]_D^{18} + 6\cdot9^\circ$ (10 min.), $\rightarrow + 10\cdot4^\circ$

equil. (conc. 2·3 in water). Found: C, 35·9; H, 7·4 per cent; calc. for $C_6H_{14}O_4NCl$: C, 36·1; H, 7·1 per cent. 'Amino-sugar X' was crystallized from a water–methanol–acetone mixture.

A comparison of the electrophoretic mobilities of the *N*-acetyl derivatives of 'pneumosamine' (M_G 0·40), 2-amino-2,6-dideoxy-L-galactose (M_G 0·29) and 2-amino-2,6-dideoxy-D-glucose (M_G 0·0) in borate buffer indicated that the hydroxyl groups on $C_{(3)}$ and $C_{(4)}$ were *cis* related, since vicinal *trans* hydroxyl groups (as in 2-acetamido-2,6-dideoxy-D-glucose) do not complex with borate[5,6]. Such *cis*-related hydroxyl groups are present in sugars having the *allo*-, *altro*-, *galacto*- and *talo*- configurations. 'Pneumosamine' and 2-amino-2,6-dideoxy-L- or -D-galactose had different paper and ion-exchange chromatographic properties and optical rotations. The best method of distinguishing between the remaining three configurations seemed to be by deamination, despite the complexity of the reaction[7,8]. A chromatographically homogeneous product was obtained from 'pneumosamine' by deamination under rigorously controlled conditions. This product migrated the same distance as 6-deoxy-L-galactose and separated on the same chromatogram from 6-deoxyallose, 6-deoxyaltrose, 6-deoxytalose and 6-deoxymannose. The deamination therefore indicated that 'pneumosamine' was probably 2-amino-2,6-dideoxytalose, and that deamination proceeded with inversion at $C_{(2)}$. An analogy may be drawn with the deamination of 2-amino-2-deoxy-D-mannose (axial amino group), which proceeds with Walden inversion at $C_{(2)}$ (refs. 9 and 10). Deamination of 2-amino-2-deoxy-D-glucose (equatorial amino group) proceeds with ring contraction and the product is an anhydro sugar[9,11]. Possibly the difference in energy between the two chair conformations of 2-amino-2,6-dideoxytalose is sufficient, under the conditions of deamination, for the conformation with an axial amino group to predominate.

'Amino-sugar X' and its *N*-acetyl derivative were found to be indistinguishable from 2-amino-2,6-dideoxy-L-galactose (L-fucosamine) and 2-acetamido-2,6-dideoxy-L-galactose by paper and ion-exchange chromatography and by electrophoresis. The infra-red spectra of an equilibrium mixture of the isolated sugar and authentic L-focusamine were almost completely superimposable. *N*-Acetylation of a crude sample of 'amino-sugar X', followed by separation on Whatman No. 3 filter paper, gave a crystallizable product of melting point 195–198° (uncorr.), undepressed on admixture with authentic *N*-acetyl-L-fucosamine, $[\alpha]_D^{20}$ − 79° equil. (conc. 0·17 in water). The infra-red spectra of an equilibrium mixture of the *N*-acetylated product and of authentic *N*-acetyl-L-fucosamine were also identical. The amino-sugar was assigned to the L-series on the basis of optical rotation data. Furthermore, it was possible to epimerize[12] '*N*-acetylpneumosamine' to an equilibrium mixture containing a product chromatographically indistinguishable from either authentic *N*-acetylfucosamine or '*N*-acetylamino-sugar X'. This affords additional evidence that 'pneumosamine' and 'amino-sugar X' are epimeric at $C_{(2)}$.

Neither 2-amino-2,6-dideoxy-L-galactose (L-fucosamine) nor 2-amino-2,6-dideoxytalose has been previously found in Nature, and the latter sugar was hitherto unknown. Its synthesis is at present being undertaken in our laboratories. The discovery of these amino-sugars in the amino-sugar – rich *Pneumococcus* species should stimulate much work, both chemical and immunological, in order to improve our understanding of the specificity of immunological reactions.

We are indebted to Profs. R. Kuhn and T. Reichstein, Drs. D. A. L. Davies and C. J. Morel for providing gifts of amino-sugars and 6-deoxyhexoses. We are also indebted to Prof. M. Heidelberger, who supplied the Type V polysaccharide. Two of us (M. J. H. and J. M. W.) thank the University of Birmingham for research grants.

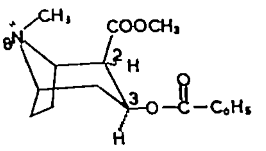
Specification of Asymmetric Nitrogen Atom. Application of the Cahn–Ingold–Prelog Nomenclature to some Tertiary Amines and Quaternary Ammonium Salts

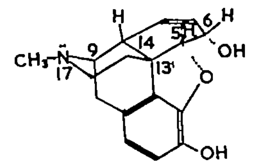
THOUGH the Cahn–Ingold–Prelog nomenclature[1] is quite generally valid for specifying asymmetric systems, and was proposed by its authors for the unambiguous description of both organic and inorganic systems, little application is to be found in the literature[2] so far relating to the characterization of nitrogen atoms of known configuration by this convention.

The specification of an asymmetric nitrogen atom follows from the general definition given by Cahn, Ingold and Prelog. Accordingly, in the case of a tertiary nitrogen atom, the three substituents attached to it should be regarded as the *a*, *b* and *c* groups, whereas the fourth substituent (*d*) of zero ordinal number is the unshared electron pair. Existence of tertiary amines of stable configuration makes it necessary to accept the orientation of the unshared electron pair of the nitrogen atom; this fact can be deduced both from quantum mechanical calculations[3] and evidence obtained in a synthetical chemical way[4].

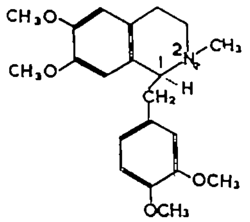
Compounds of known configuration and containing an asymmetric tertiary nitrogen atom are known among the tropane alkaloids[5]. Fodor *et al.*[6] showed that in the case of the tertiary tropane derivatives investigated, the substituents attached to the nitrogen and not contained within the ring had N-α-configurations. Summarizing the results of the investigations



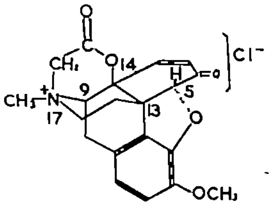
I



II



III



IV

of Hardegger and Ott[7] relating to the absolute configuration of the C_2 and C_3 carbon atoms of (−)-cocaine, and those of Kovács, Fodor and Halmos[8] as regards the absolute configuration of the asymmetric nitrogen atom of the skeleton, natural (−)-cocaine (I) may be described as having a 2*R* : 3*S* : 8*R* configuration.

In the course of earlier research work we[9] reported the configurational stability of the tertiary nitrogen atom of the morphine skeleton. Assuming an equatorial position of the N-methyl group (which is also supported by our recent investigations[10]) the asymmetric tertiary nitrogen atom will be of *S*-configuration. Consequently, morphine (II) should be regarded as having 5*R* : 6*S* : 9*R* : 13*S* : 14*R* : 17*S* configuration[11].

It is known from the work of Corrodi and Hardegger[12] that the C_1 atom of (+)-laudanosine (III) has the *S*-configuration. Since Knabe[13] ascribes an equatorial steric position for the C_1 substituent of laudanosine and an axial position for the N-methyl group, it follows that the nitrogen is of *R*-configuration.

The assignment of asymmetric quaternary ammonium salts is obvious. It follows that 14-hydroxycodeinone lactone hydrochloride[10] (IV) may be characterized by the configuration 5*R* : 9*R* : 13*S* : 14*R* : 17*S*.

Application of the Cahn–Ingold–Prelog nomenclature, in the sense shown here, to tertiary amines having nitrogen atoms of known configuration and of configurational stability, as well as to quaternary ammonium salts, permits a more complete and unequivocal description of the compounds.

BIOCHEMISTRY

Non-Enzymic Decarboxylation of Methionine by Ferrous Ion

IN work on the precursors of the volatile sulphur components of vegetable flavours and odours, a non-enzymic oxidative decarboxylation of methionine in the presence of Fe^{2+} was observed. The final reaction mixture had a very pronounced odour. Unlike other well-known Fe^{2+} oxidations, there was no need for added hydrogen peroxide[1,2] or ascorbic acid[3,4]. The addition of a metal chelating agent such as ethylenediamine tetraacetate (EDTA) or citrate was very stimulatory. Table 1 shows the absolute requirement for Fe^{2+}. Only Fe^{2+} was able to carry out this decarboxylation. Mg^{2+}, Mn^{2+}, Ca^{2+}, Co^{2+}, Ni^{2+}, Zn^{2+}, Cu^{2+} and Al^{3+} were completely ineffective. Fe^{3+} was 1 per cent as effective as Fe^{2+}.

Table 1. REQUIREMENTS FOR METHIONINE DECARBOXYLATION

Reaction system*	mμc. ^{14}C as CO_2
Complete	58·8
Minus Fe^{2+}	0
Minus EDTA	13 1
Complete, 0·5 μmole Fe^{2+} instead of 5 μmoles	7·2

* Complete reaction system contained 2 μmoles 1-^{14}C DL-methionine containing 0·5 μc., 5 μmoles ferrous chloride, 5 μmoles EDTA, 100 μmoles phosphate buffer *p*H 7, and distilled water to a final volume of 2 ml. This solution was in the main chamber of a Warburg vessel. In the centre well was 0·2 ml. 20 per cent potassium hydroxide and in the sidearm 0·8 ml. 5 *N* sulphuric acid. The reaction was incubated 90 min. at 30° C., the acid tipped and the potassium hydroxide collected 10 min. later. The absorbed carbon dioxide was counted as a gas in an ionization-type counter.

The participation of free hydrogen peroxide did not seem to be indicated since the addition of crystalline catalase only inhibited the reaction by 19 per cent. The reaction was found to be aerobic in nature. In a nitrogen atmosphere the amount of carbon dioxide produced from the methionine carboxyl group was decreased by 88 per cent. The residual activity remaining in the nitrogen-flushed reaction mixture was probably due to the small amount of dissolved oxygen which had not been displaced by the method of flushing used.

The addition of ascorbic acid to the reaction mixture gave a large increase in the amount of carbon dioxide released. In the presence of ascorbic acid, Fe^{3+} was as effective as Fe^{2+}. EDTA was required for the stimulatory effect of ascorbic acid to be demonstrated. These results are summarized in Table 2.

Table 2. ASCORBATE EFFECT ON DECARBOXYLATION

Reaction system*	Total counts as $Ba^{14}CO_3$
Complete	23,990
Minus EDTA	7,255
Plus ascorbate	42,145
Plus ascorbate, minus EDTA	8,834
Complete, Fe^{3+} for Fe^{2+}	332
,, ,, ,, ,, plus ascorbate	42,885
,, ,, ,, ,, ,, ,, minus EDTA	8,804

* Reaction system and conditions same as in Table 1. 5 μmoles ferric chloride and 10 μmoles ascorbic acid are added where indicated. Absorbed $^{14}CO_2$ was precipitated, plated and counted as $Ba^{14}CO_3$ by a thin-window Geiger–Müller-type counter.

The question whether the ascorbic acid effect is due to maintenance of Fe^{2+} concentration or to a different mechanism is left open. Preliminary work indicates that the reaction is not of an important general nature as regards amino-acids. 1-^{14}C DL-alanine was decarboxylated to only 1 per cent and 1-^{14}C DL-methionine sulphoxide to only 6 per cent that of an equivalent amount of methionine under the same conditions.

A large-scale reaction was carried out in order to isolate the reaction product. 250 µmoles phosphate buffer *p*H 7, 200 µmoles ferrous chloride, 200 µmoles EDTA *p*H 7, and 500 µmoles DL-methionine in a final volume of 9·5 ml. were incubated for 90 min. at room temperature with constant shaking. The reaction mixture was then acidified with 3 ml. 10 per cent trichloracetic acid, and 10 ml. 0·01 *M* 2,4-dinitrophenylhydrazine in 2 *N* hydrochloric acid were added. After cooling at 10° C. overnight, the precipitate which formed was removed by filtration and after drying over calcium chloride was recrystallized from ethanol–water. An infra-red spectrum of a potassium bromide pellet of the recrystallized material was obtained from 3 to 15µ. This spectrum was identical with that of a known sample of the 2,4-dinitrophenylhydrazone of methional. It would appear that the decarboxylation is also accompanied by some deamination to yield the corresponding aldehyde.

I wish to thank Mrs. Edith L. Gong and Mr. Glen F. Bailey for the infra-red analyses.

Chromatography of the Proteins from Wheat Flour soluble in Acetic Acid

THE heterogeneity of the gluten fraction of wheat flour has been well established by the moving boundary[1–3], starch-gel[4] and filter paper curtain[5] methods of electrophoresis. The last-mentioned technique has also been used for fractionation purposes. The chromatographic separation of gluten into four major electrophoretically distinguishable components by stepwise elution from carboxymethyl-cellulose has also been reported briefly[1,6]. This communication reports the resolution of the acetic-acid-soluble fraction of flour into six components by gradient elution from carboxymethyl-cellulose.

Flour, milled from Gabo wheat to approximately 70 per cent extraction on a Buhler laboratory mill, was extracted successively with water-saturated *n*-butanol (1 treatment), 0·01 *M* sodium pyrophosphate (*p*H 7·0 ; 4 treatments) and 0·05 *N* acetic acid (*p*H approximately 3·5 ; 4 treatments) in accordance with the procedure described by Coates and Simmonds[7]. Under these conditions 18–20 per cent of the nitrogen was soluble in the sodium pyrophosphate, 55–60 per cent was soluble in the acetic acid and the remainder could be extracted with 0·1 *N* sodium hydroxide. The butanol extract contained only 0·5–2·0 per cent of the total nitrogen.

The acetic acid extract, containing 50–100 mgm. of protein nitrogen in 100 ml., was dialysed against 0·005 *M* sodium acetate buffer *p*H 4·1, and loaded on to a carboxymethyl-cellulose column (1·5 × 15 cm.) previously equilibrated with the same buffer. Under these conditions most of the protein was bound to the carboxymethyl-cellulose, but a small amount, designated fraction α, passed unretarded through the column. In order to remove completely the remainder of fraction α, the column was washed with a further 30 ml. of the 0·005 *M* sodium acetate buffer, followed by 300 ml. of the same buffer containing 1·0 mole of dimethyl-formamide per litre (final *p*H 4·1). Three protein components (peaks β, γ and δ in Fig. 1) were then eluted using a sodium chloride gradient running from 0 to 1 *M*, total volume 1 l., the molar concentrations of sodium acetate and dimethyl-formamide being maintained at 0·005 and 1·0 respectively. Two additional components (peaks ε and θ in Fig. 1) could be eluted by running a further gradient from acetate buffer 0·005 *M* in sodium acetate (*p*H 4·1) to a phosphate solution *p*H 12, containing 0·005 mole of trisodium phosphate per litre, both solutions being 1·0 *M* with respect to sodium chloride and dimethyl-formamide : the total volume of this gradient was also one litre. Any protein still adhering to the column was then removed with 0·1 *M* sodium hydroxide (peak ω in Fig. 1) : this peak is not considered to represent a definite protein component and has been included in the elution diagram to indicate the amount of protein not recovered from the column by the two gradients employed. Fig. 1 shows the sequence of the elution pattern and the *p*H of the effluent at each stage, together with an estimate of the protein distribution between peaks, determined by the method of Lowry, Rosebrough, Farr and Randall[8].

Using this procedure, a series of acetic acid extracts from 12 Australian flours was examined, 100 mgm. of protein nitrogen being loaded in each case. This allowed a resolution of the main protein components similar to that shown in Fig. 1. However, the solubilities of these were such that material in the peak tubes of components β, δ, ε and θ was precipitated on elution from the column. This precipitate was soluble in 0·05 *M* acetic acid. The only obvious difference in the elution patterns obtained was a variation in the size of the δ peak, which was not even detected in several cases.

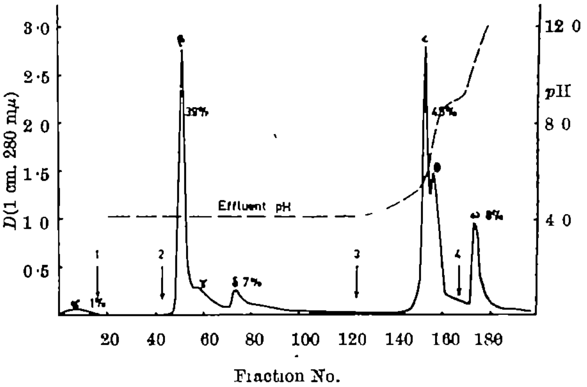

Fig. 1. Elution of flour protein components from a carboxymethyl-cellulose column. Loading : 100 mgm. of protein nitrogen derived from the 0·05 *M* acetic acid soluble fraction of Gabo flour Column : 1·5 cm. × 15 cm., equilibrated to *p*H 4 1 with 0 005 *M* sodium acetate buffer. Size of fractions . 12 ml. Eluting solvents changed as follows . Arrow No. 1, 0 005 *M* sodium acetate containing 1 0 *M* dimethyl formamide ; *p*H 4 1. Arrow No. 2, gradient started to 0 005 *M* sodium acetate containing 1 0 *M* dimethyl formamide and 1·0 *M* sodium chloride ; *p*H 4·1. Arrow No. 3, gradient started from previous final solvent to 0 005 *M* trisodium phosphate containing 1·0 *M* dimethyl formamide and 1 0 *M* sodium chloride ; *p*H 12·0. Arrow No. 4, 0·1 *N* sodium hydroxide

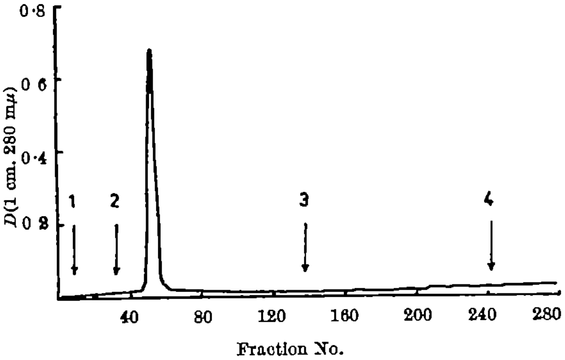

Fig. 2. Rechromatography of fraction β (Gabo flour) on carboxymethyl-cellulose. Loading: 15 mgm. of protein nitrogen. Column: 1·5 cm. × 15 cm., equilibrated to pH 4·1 with 0 005 M sodium acetate buffer. Size of fractions: 10 ml Order of change in eluting solvents as indicated in Fig. 1

Rechromatography of fraction β on carboxymethyl-cellulose gave a symmetrical elution peak as shown in Fig. 2, but there is no certainty that this or any of the peaks would behave as a single homogeneous protein when subjected to other methods of fractionation. In fact, Elton and Ewart[4] have demonstrated by starch-gel electrophoresis the presence of at least eight components in acetic acid extracts of glutens obtained by hand-washing flours with distilled water. It is possible that some of these components correspond to traces of albumin and globulin fractions[9], which would have been removed during our preliminary treatment of the flour with sodium pyrophosphate.

Dimethyl formamide, which has been used by Vercouteren and Lontie[10] to disperse gluten, was added to the buffer to prevent precipitation of protein from solutions of ionic strength greater than 0·04. In this case it has allowed the successful elution of components from the column using salt and mild pH gradients. There is evidence that the reaction between hydrogen bond - breaking agents and gluten is reversible[11,12].

Full details of this work will be submitted for publication in due course.

Optical Rotatory Dispersion of the Thrombin-induced Conversion of Fibrinogen to Fibrin Monomer

CONSIDERABLE evidence has now accumulated suggesting that the thrombin-induced conversion of fibrinogen to fibrin is a reversible triphasic reaction which may be represented thus[1]:

Step 1 Proteolysis $F \overset{T}{\rightleftarrows} f + P$
Step 2 Polymerization $nf \rightleftarrows f_n$
Step 3 Clotting $mf_n \rightleftarrows$ fibrin

where F is fibrinogen, T is thrombin, f is fibrin monomer, P represents non-protein nitrogenous material consisting primarily of two acidic peptides of molecular weights 1,900 and 2,400, and f_n represents intermediate polymers where n and m are variable numbers.

Hydrogen bonding has been implicated in this reaction scheme in two important aspects. First, the polymerization of f to intermediate polymers (step 2) has been shown to proceed through the formation of intermolecular hydrogen bonds between tyrosyl donors and histidyl acceptors[2]. Secondly, it has been suggested that either the donor or acceptor groups are unavailable in the intact fibrinogen molecule because they are hydrogen-bonded to the highly acidic groups of the two peptides released in step 1; they become available only when the hydrogen bonds in which they are participants are broken[1]. If such hydrogen bonds exist in the native fibrinogen molecule, they should be playing a significant part in stabilizing that portion of the molecule which is regularly folded; conversely, the rupture of these bonds should decrease the stability of the helical portions of the molecule. In order to observe whether configurational changes of this type accompany the thrombin-catalysed proteolysis of fibrinogen, measurements of the optical rotatory dispersion of this system were undertaken. To facilitate studies of step 1 free of steps 2 and 3, use was made of the finding that step 1 will occur in 1 M sodium bromide at pH 5·3 without the subsequent polymerization of fibrin monomer[3].

The bovine fibrinogen used ('Pentex' lot 20F 14) was refractionated by Laki's procedure[4]; a product which was 95 per cent clottable, as assayed by the method of Laki[4], was obtained. A purified citrate-activated thrombin preparation kindly supplied by Dr. W. H. Seegers was used. This product, received and stored in aqueous solution, had an activity of 4,000 tosylarginine methyl ester units/mgm. The optical rotatory measurements were carried out on a Rudolph model 260 automatic recording spectropolarimeter using a xenon compact arc-lamp as the light source. Kinetic measurements were made at 400 and 589 mμ. At the beginning and end of each reaction a complete optical rotatory dispersion curve was run; in these cases the results were evaluated in accordance with the method of Yang and Doty[5], by plotting the product of the specific rotation and squared wave-length versus specific rotation.

Column 2 of Table 1 lists the variation of optical rotation with wave-length for a 2·5 per cent fibrinogen solution in 1 M sodium bromide at pH 5·3 (0 time curve). It is to be noted that $[\alpha]_D$ is $-$ 53° and λ_0, evaluated from the slope of the plot of $\lambda^2[\alpha]$ versus $[\alpha]$, is 227 mμ; these values are to be compared with an $[\alpha]_D$ of $-$ 48·6° and a λ_0 value of 256 mμ, obtained

Table 1. OPTICAL ROTATORY DISPERSION RESULTS FOR FIBRINOGEN AND FIBRIN MONOMER

Wave-length, λ (Å.)	$-[\alpha]$ for fibrinogen (2·63 per cent)	$-[\alpha]$ for fibrin monomer (2 55 per cent) formed from fibrinogen of column 2	$-[\alpha]$ for fibrin monomer (3·2 per cent) formed from fibrin
5890	53	51	53
5500	65	63	62
5000	84	80	81
4500	103	99	100
4250	122	118	116
4000	141	141	141
3800	171	165	162
3700	—	—	181
3600	201	200	197
3500	224	223	216
3400	257	247	—

3200	327	325	—
λ_0 (mμ)	226·9	228 0	225·8

by Yang and Doty for fibrinogen in 0·3 *M* potassium chloride at *p*H 6·3[5]. The increase in lævorotation and decrease in dispersion constant in the bromide solvent are consistent with the idea that this medium is a denaturing one[6] and that it prevents steps 2 and 3 from setting in because of its ability to break hydrogen bonds.

At zero time, thrombin was added to the fibrinogen solution in the polarimeter cell such that its final concentration was 100 units/ml. The cell contents were mixed and the rotations at 400 and 589 mμ were followed for 20 hr. (half-time about 3 hr. at 25° C.[7]): these were not found to vary significantly, suggesting that the kinetics of the reaction are not reflected in optical rotatory changes. In this respect, this reaction differs from other examples of limited proteolysis reactions, notably the zymogenic activation reactions of chymotrypsinogen, trypsinogen and pepsinogen, all of which are accompanied by easily measurable changes in optical rotation[8]. At the completion of the reaction the solution was exhaustively dialysed against 1 *M* sodium bromide at *p*H 5·3 in order to remove the liberated peptides and an optical rotatory dispersion curve was carried out on the remaining fibrin monomer (see column 3 of Table 1). As can be seen, none of the rotations for the fibrin monomer differs significantly from the values obtained for fibrinogen alone; furthermore the calculated λ_0 values agree within experimental error, suggesting that the degree of ordered configuration in the two molecules is the same. As a further check that the dispersion results of column 3 represent the values for fibrin monomer and not those of monomer plus adsorbed contaminants, purified fibrin monomer was obtained by dissolving fibrin in 1 *M* sodium bromide at *p*H 5·3 (that is, by reversing steps 2 and 3 in the bromide solvent[3]). The optical rotatory dispersion of a 3·2 per cent solution of this material is presented in the final column, from which it is seen that essentially identical optical rotatory results are obtained for fibrin monomer prepared by either the forward or backward reactions.

The virtual identity in optical rotatory properties of native fibrinogen and fibrin monomer suggests that the two peptides liberated in the proteolysis reaction must be essentially devoid of helix; otherwise their removal would have resulted in different dispersion constants for the two solutions. This finding is consistent with the preliminary amino-acid analysis of the two peptides[9], which reveals in each the presence of a number of dicarboxylic amino-acid residues as well as two prolines; both the high density of negative charge and presence of two imino-acids would tend to favour a randomly oriented configuration. Finally, the lack of optical rotatory change associated with the kinetic process implies that the donor or acceptor groups liberated in step 1 appear, more likely as the result of an unmasking process, that is, a removal of a steric impediment exerted by the peptides rather than by rupture of side-chain hydrogen bonds which would be expected to have been reflected in optical rotatory changes.

We are indebted to Dr. W. H. Seegers of Wayne State University for his generous gifts of purified thrombin and to Mr. John Carson for his skilled technical assistance.

The Problem of 'Methæmocyanin'

IT was thought that, analogously to the iron in hæmoglobin, the copper of hæmocyanin remained in the cuprous (Cu^+) state when the pigment took up oxygen[1]. This was questioned[2] because the characteristic blue colour of the cupric ion (Cu^{++}) appeared when oxyhæmocyanin was formed, as well as on other grounds. It has since been shown[3], using the hæmocyanin of *Busycon*, *Loligo*, *Homarus* and *Limulus*, that in fact half the copper becomes Cu^{++} and the rest remains Cu^+. There was occasion to confirm this on the bloods of *Helix* and *Maia*, in the course of other work[4]. Klotz and Klotz[3] showed that the oxygenation probably depends on the co-operation of the two ions. A number of further differences in properties between hæmocyanin and hæmoglobin also were explained by their important discovery.

There still remains some obscurity, however, concerning 'methæmocyanin', which is prepared, like methæmoglobin, by the action of strong oxidizing agents on the pigment[5]. It is not clear why methæmocyanin should still be able to take up oxygen reversibly, with a colour change essentially similar to that of hæmocyanin itself. Since half the copper is converted to Cu^{++} even by atmospheric oxygen it appears to be more easily oxidized than the iron of hæmoglobin. Yet the latter is entirely converted to ferric in methæmoglobin and can no longer take up oxygen reversibly. It has been confirmed, using *Maia* blood, that hæmocyanin does retain this ability for reversible oxygenation–deoxygenation, with colour change, in the presence of such strong oxidizing agents as potassium ferricyanide and potassium permanganate. If the oxidizing agent is added to two samples of deoxyhæmocyanin and one is then shaken with air, the change in colour is readily apparent by comparison with the control.

It is also clear that oxidizing agents do not increase the amount of blue Cu^{++} ion present in oxyhæmocyanin or produce any in deoxyhæmocyanin. There is no increase in extinction of light of 570 mμ wavelength when *Maia* blood is saturated with potassium chlorate or treated with other colourless oxidizing agents, such as potassium iodate and hydrogen peroxide (neutralized with sodium peroxide). This may be confirmed also using potassium ferricyanide which absorbs very little light at that wave-length. The evidence is that the copper is quite 'unavailable' to these and also to other agents, though available to atmospheric oxygen. For example, sodium diethyldithio-carbamide, a sensitive, specific reagent for copper ions, gives no colour reaction with native *Maia* blood, though this appears sharply at a certain stage of denaturation, for example, by heating to 60° C. This applies equally to the reaction with 2 : 2′-diquinolyl, a specific colour reaction of the Cu^{+} ion[3], alone.

If an excess of such oxidizing agents as potassium ferricyanide and potassium permanganate is added to *Maia* blood, which is then denatured to 'reveal' the copper ions, it is found that all are now in the Cu^{++} state. Oxidation of free Cu^{+} to Cu^{++} is presumable instantaneous, as shown also by adding the oxidizing agent after denaturation in the presence of diquinolyl, in a suitable solvent (glacial acetic acid is most convenient since it also denatures the protein, and redissolves it on warming). Using potassium chlorate as oxidizing agent, some of the Cu^{+} survives for a time after release by denaturation and the pink colour with diquinolyl fades slowly.

A further feature of interest is that the Cu^{++} of denatured hæmocyanin oxidized by potassium permanganate returns spontaneously to Cu^{+}, slowly at room temperature and more rapidly on warming. Preparations from oxyhæmocyanin give a final yield of Cu^{+} about half the amount obtained from deoxyhæmocyanin preparations, indicating that ions initially in the Cu^{++} state remain so. However, on repeated oxidation with potassium permanganate, followed by spontaneous reduction, the amount of Cu^{+} progressively increases. Reducing agents still readily reduce the Cu^{++} to Cu^{+}. Potassium dichromate shows the same behaviour as potassium permanganate ; but ferricyanide, chlorate and hydrogen peroxide, in excess, appear to oxidize irreversibly. Using minimal amounts of hydrogen peroxide the ion can be reduced once more simply by exposure to low oxygen tension, over alkaline pyrogallol, so that denatured hæmocyanin might still be a reversible oxygen carrier, under appropriate conditions.

It is interesting that potassium permanganate should have been used[5] to prepare 'methæmocyanin', rather than ferricyanide, which is used for methæmoglobin and seems more capable of effecting irreversible change. The reason given was that ferricyanide does not release oxygen from oxyhæmocyanin, though there seems no good evidence that permanganate does. In any event, however, neither seems to affect the copper of the native pigment. This seems much more sensitive to reducing than to oxidizing agents therefore.

Some of these properties of hæmocyanin are mimicked by synthetic copper proteins, a further indication that there is no special prosthetic group in hæmocyanin. When ten volumes of 1 per cent egg albumen solution are added to one of 0·1 per cent copper sulphate, a copper protein is formed, the colour of the Cu^{++} ion becoming intensified. Moreover, on adding diquinolyl in *iso*amyl alcohol a positive reaction for the Cu^{+} ion gradually develops. The protein is near its isoelectric point and denatures spontaneously. At a more alkaline *p*H it can be denatured by heat without release of the Cu^{+} ion which, however, appears on acidification. The albumen appears to bind and to reduce some of the copper. It is even capable of reducing Cu^{++} added after it has been denatured with acetic acid. The Cu^{+} of the denatured copper protein, in acetic, is oxidized by potassium permanganate and spontaneously reduces on standing. This is also true of the copper protein of *Lithobius*[4], in the reduced, denatured state.

Thus it seems that proteins commonly have the power to reduce Cu^{++} to Cu^{+} and to do so repeatedly following reoxidation, whether it is bound in non-ionic form to the native protein or associated as an ion, after denaturation. In native hæmocyanin, at least, the $Cu^{+} \rightleftharpoons Cu^{++}$ change is associated with reversible oxygenation, and this process is not affected by strong chemical oxidizing agents. It would seem reasonable to keep the term 'methæmocyanin' in abeyance until there is evidence of a definite compound similar to methæmoglobin.

Activation of Cockroach Acetylcholinesterase by Water-miscible Organic Solvents

IT is common practice to treat insects with poisons dissolved in acetone or dioxane. Also, water-insoluble anti-cholinesterases are dissolved in organic solvents to determine their inhibition of acetylcholinesterase *in vitro*. While studying functional properties of acetylcholinesterase of the American cockroach[1], evidence was obtained that inclusion of acetone or some alcohols in a Warburg reaction mixture resulted in greater hydrolysis of acetylcholine. These results are given in Table 1, where 0·1 ml. of the organic solvents was included in a Warburg reaction mixture of salts, buffer, substrate and tissue homogenate, final volume, 2·7 ml. The increase in hydrolysis of acetylcholine was most striking in the presence of *n*-propanol and *n*-butanol. Further work showed that the optimal concentration of *n*-butanol for maximal hydrolysis of acetylcholine was 0·05 ml. in 2·7 ml. of reaction mixture. Acetone differed in this respect and optimal activity was obtained at 0·25 ml. of acetone in 2·7 ml. of reaction mixture.

Bovine purified erythrocyte and homogenates of housefly thoracic ganglia and mouse brain were used as sources of acetylcholinesterase for a comparison

Table 1. Effect of Various Solvents* on the Rate of Hydrolysis of Acetylcholine by Acetylcholinesterase from Cockroach Ganglia

Solvent	Average b_{30}†	Activation ratio $\frac{\text{Solvent } b_{30}}{\text{Control } b_{30}}$
iso-Octane	48·0	1·05
Dioxane	48·1	1·05
Ethyl alcohol	50·7	1·1
Acetone	71·5	1·56
iso-Butanol	106·0	2·31
iso-Amyl alcohol	124·5	2·72
iso-Propanol	132·1	2·89
n-Propanol	142·7	3·12
n-Butanol	180·8	3·95
Control	45·7 ± 2·1	

* 0·1 ml. acetone in 2·7 ml. of reaction mixture.

† b_{30} refers to the amount of carbon dioxide evolved in 30 min. after correction for non-enzymatic hydrolysis.

with homogenates of the thoracic nerve cord of the cockroach in the presence of solvents. The results given in Table 2 for acetone show that only the acetylcholinesterase of the cockroach was activated. The acetylcholinesterase from the other sources was inhibited when compared with controls in which acetone was omitted. This result shows a striking difference in the acetylcholinesterase of the cockroach-hydrolysing acetylcholine.

Table 2. Effect of Acetone* on Acetylcholinesterases from Various Sources

Source	Average b_{30}† control	Average b_{30} with acetone	Activation ratio $\frac{\text{Acetone } b_{30}}{\text{Control } b_{30}}$
Cockroach thoracic ganglia	48·2	83·1	1·72
Housefly thoracic ganglia	37·4	31·3	—
Mouse brain	140·4	115·8	—
Bovine purified erythrocyte	225·4	183·0	—

* 0·1 ml. acetone in 2·7 ml. of reaction mixture.

† b_{30} refers to the amount of carbon dioxide evolved in 30 min. after correction for non-enzymatic hydrolysis.

As the above results were determined with homogenates, experiments were then carried out with acetone and butanol powders of the nervous tissue of the cockroach. Manometric determinations of the reconstituted acetylcholinesterase showed that the activation effect of *n*-butanol and acetone was not eliminated when these solvents were included in the reaction mixture. Furthermore, these results showed that the effect found with homogenates was not due to a liberation of more acetylcholinesterase from tissue fragments or to an inhibiting factor. The use of differential centrifugation and various substrates gave positive evidence that only one enzyme hydrolysed acetylcholine. The enzyme appears to be particulate, and when solubilized by use of sodium cholate similar activation was found with *n*-butanol.

Results obtained on the kinetics of hydrolysis of acetylcholine and other substrates in the presence of *n*-butanol and anticholinesterases gave evidence of the possible mechanism of activation. This appears to be an effect of the solvents on the active sites of the acetylcholinesterase of the cockroach. If so, a specific property has been found for the acetylcholinesterase of the nervous tissue of the cockroach. Details of these results will be published elsewhere.

O-Demethylation as a Biosynthetic Pattern in the Formation of Opium Alkaloids

Comparative rates of incorporation of carbon dioxide labelled with carbon-14 led to the proposal[1] that, in *Papaver somniferum*, thebaine is the first octahydrophenanthrene alkaloid formed, and is converted by successive O-demethylations to codeine and finally to morphine. Although this sequence seemed best to explain the labelling ratio among these three alkaloids, conclusive proof was lacking. The results described here, considered with the previous data[1], constitute proof of this interrelationship.

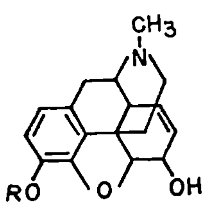
Three plants of *P. somniferum*, each 2½ months old, were root-fed, respectively, labelled morphine, codeine and thebaine, which were obtained from a three-day biosynthesis with labelled carbon dioxide[1]. The alkaloids were absorbed from a weak potassium dihydrogen phosphate solution over the course of 42 hr., and the plants then were frozen immediately and the alkaloids isolated as previously described[1]. The results are given in Table 1.

Table 1. Carbon-14 labelled Alkaloid Feeding Experiments

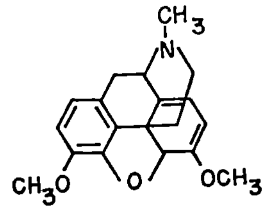
Plant No.	Alkaloid fed	Alkaloid isolated	Amount (mgm.)	Total activity (d.p.m.)	Specific activity (d.p.m./μmole)
1	Morphine	—	0·089 absorbed	621,000	2,000,000
		Morphine	1·53	337,000	62,800
		Codeine	0·088	none	—
		Thebaine	0·021	none	—
2	Codeine	—	0·12 absorbed	3,500,000	8,650,000
		Morphine	1·03	355,000	98,300
		Codeine	0·28	402,000	425,000
		Thebaine	0·042	none	—
3	Thebaine	—	0·04 absorbed	2,290,000	18,000,000
		Morphine	0·87	77,100	19,200
		Codeine	0·19	66,000	105,000
		Thebaine	0·026	29,900	321,000

Of the three alkaloids isolated from the morphine-fed plant, only morphine was radioactive; of those from the codeine-fed plant, only morphine and codeine were active; while from the thebaine-fed plant all three alkaloids were active. Since the alkaloids fed were from a biosynthesis with labelled carbon dioxide, they would be labelled both in the methyl groups and ring skeleton[4]. Hence it was necessary to demethylate and check ring skeleton activity in the isolated alkaloids in order to establish that incorporation of radioactivity was not simply due to transmethylation. The necessary degradations[1] were performed on thebaine which was fed to plant 3 and on the morphine and codeine isolated from that plant after 42 hr. It was found that the ratio of methyl group to ring skeleton activity was approximately the same in the thebaine as in the morphine and codeine isolated. Therefore, incorporation of radioactivity was not due to transmethylation, and the entire ring skeleton was converted to codeine and thence to morphine in accordance with the proposed scheme[1].

A comparison of the specific activities of the codeine and thebaine which were fed with the specific activities of the same alkaloids isolated at the end of 42 hr. shows that the final values are much lower than one would expect on the basis of pool dilution alone. This indicates a relatively rapid synthesis and conversion of the alkaloids, especially of thebaine, and a high percentage incorporation of specific activity would not be expected. Somewhat more meaningful



Morphine, $R = H$
Codeine, $R = CH_3$



Thebaine

in this case is the incorporation of total activity. Based on ring skeleton activities derived from the above-mentioned degradations, a 13 per cent incorporation was achieved from codeine to morphine in plant 2, while the incorporation from thebaine to morphine and codeine in plant 3 was 7·5 and 5·0 per cent, respectively. The values listed in Table 1 for the amount of alkaloid absorbed are based on loss of activity from the feeding solution. Experiments now under way show that a rapid adsorption or absorption of the alkaloids by the root hairs occurs, but that the further translocation is relatively slow. After the 42-hr. biosyntheses reported here, these root hairs had been removed and were not included in the total plant analysis. Therefore, the values for the percentage incorporation of total activity given above are undoubtedly minimal.

The proved conversion of thebaine to codeine and codeine to morphine clearly establishes O-demethylation as a metabolic pathway. This is in contrast to the commonly held concept[2] that the O-methylated alkaloids are metabolic end-products. Because of the relatively rapid synthesis and interconversion of alkaloids which has been found in this and the previous work[1], such demethylations could be a significant part of the total plant metabolism and perhaps provide one answer to the century-old problem of alkaloid function.

This investigation was sponsored in part by the United States Atomic Energy Commission.

Phenolase and Pectic Enzyme Activity in the Chocolate Spot Disease of Beans

The chocolate spot disease of beans (*Vicia faba* L.) caused by *Botrytis fabae* Sard. is so named because an early result of infection by the fungus is a small brown lesion on leaf or stem. In the course of studying the factors controlling the development of these lesions, it was found that the latent phenolase of bean leaves could be activated by certain pectic substances and by a soluble cellulose derivative in a way similar to that described by Kenten[1] for anionic wetting agents. The result of phenolase action, with the naturally occurring leaf phenols as substrate, is an intense brown coloration.

Kenten[1,2] showed that aqueous extracts of bean leaves had very little phenolase activity, measured by oxygen uptake or by coloured end-products, unless extracts were first exposed to acid or alkaline conditions, precipitated by ammonium sulphate, or incubated with certain anionic wetting agents. In the present experiments, mixtures of dialysed leaf extracts, citrate/phosphate buffer and activators were incubated for appropriate periods. They were then added to catechol or dihydroxyphenylalanine (DOPA) at *p*H 7·0. Phenolase activity was measured in an EEL colorimeter with green filter 623. Kenten's results were confirmed with sodium dioctyl sulphosuccinate as the activating agent; the optimum *p*H for activation was 5·5, and at this *p*H the buffer alone had little effect. Solutions of sodium polypectate, polygalacturonic acid and pectin had an optimum *p*H for activation of 4·5, and the buffer alone had a slight activating action at this *p*H. Monogalacturonic acid also activated the phenolase, but was less effective than the polymers; with carboxymethylcellulose, activation was most rapid between *p*H 4·0 and 4·5.

It is likely that soluble pectic substances are liberated from walls during the invasion of tissues by *Botrytis fabae* because the fungus readily produces polygalacturonase in culture. Enzymatic hydrolysis of sodium polypectate and pectin to short-chain polymers did not destroy the ability to activate the phenolase.

Filtrates from cultures of *B. fabae* on certain media containing pectic substances rapidly reduce the viscosity of pectic substances in solution. These filtrates also disintegrate bean stem tissue, but if leaf extracts are included in the original media the filtrates have little or no polygalacturonase activity, and do not disintegrate stem tissue. Other results suggested that the enzyme was inactivated by substances formed following the oxidation of phenols in the leaf extract, and direct evidence for this was obtained in the following experiment. Phenolase was activated by carboxymethylcellulose at *p*H 4·0 and allowed to oxidize DOPA at *p*H 7·0 for 6 hr.; red-brown products had now developed. Equal volumes of oxidized DOPA and *B. fabae* culture filtrate were mixed at *p*H 7·0. Viscosity-reducing activity changed little over 2 hr. in the control with DOPA, but in the presence of oxidized DOPA, although there was no immediate effect, activity was markedly reduced after 10 min., and, after 1 hr., polygalacturonase activity was very low.

From these and other experiments, it would appear that the formation of a chocolate spot results from an interaction of the polygalacturonase systems of the fungus and the phenolase systems of the host. Fungal polygalacturonase probably kills host cells rapidly[3] and liberates the phenolase system. It also degrades cell walls and so liberates pectic substances which have been shown to activate host phenolase between *p*H 4·0 and 5·0. This will be followed by the oxidation of host phenols and the formation of dark brown polymeric products, which now inactivate the polygalacturonase of the pathogen.

A hypothesis based on interactions of this sort could explain why chocolate spot lesions are generally limited in size and why the tissue of the lesion remains coherent for some time.

Absorption and Breakdown of Iron–Ethylenediamine Tetraacetic Acid by Tomato Plants

JACOBSON[1] was the first to show that plants could utilize iron supplied as the ferric chelate of ethylenediamine tetraacetic acid (Fe–EDTA). Subsequent workers[2,3] have concluded from experiments with isotopically labelled chelating agents that the iron was released after the uptake of the entire molecule by plant roots. Tiffin and Brown[4], however, showed that, at least initially, iron was absorbed by roots from a phenolic analogue of Fe–EDTA while most of the chelating agents remained in the culture solution. The absorption of Fe–EDTA was therefore further examined, using the iron chelate labelled in both portions of its molecule.

Tomato plants were raised from seed germinated in acid-washed sand and grown in an iron-free nutrient solution in the glasshouse. Ten days after the first true leaves had appeared, three plants of uniform size were transferred to each of six culture dishes. The nutrient solution included 1 p.p.m. of iron as Fe–EDTA, prepared from equimolar amounts of ferric chloride labelled with iron-59 and EDTA labelled with carbon-14 in the 2-position of the acetate group. The stability of the iron chelate in the nutrient solution was checked by keeping a further replicate free from plants under the same experimental conditions. During the experiment light was excluded from the nutrient solution and its *p*H was maintained at 5–6.

After 10, 17 and 24 days the plants and nutrient solution in two dishes were taken for isotope analysis. The plants in each dish were bulked, divided into tops and roots and dried at 65° C. overnight. For iron-59 assay, the material was digested with nitric and perchloric acids and the γ-radiation measured in a scintillation counter. For carbon-14, the plant material was oxidized with a Van Slyke acid mixture, the carbon-14 was collected as barium carbonate and counted under an end-window Geiger–Muller tube[5]. Solutions were evaporated to dryness in the presence of inactive carrier before oxidation and assay. No iron-59 was present in the barium carbonate precipitates. The iron-59 counts were converted to μgm. iron; carbon-14 results were expressed as μc. since the chemical form of this isotope was uncertain (Table 1).

Almost all the added iron was recovered either from the solutions or from the plants; by contrast the carbon-14 recovered fell steadily to about 60 per cent of its original value after 24 days, indicating decomposition of the EDTA. Both isotopes were almost completely recovered from the solution in which no plants were grown. The loss of carbon-14 was therefore not due to decomposition of the Fe–EDTA in the nutrient solution, but to absorption and breakdown in the plants.

After 10 days the plants had absorbed about 41 per cent of the added iron but only 26 per cent of the carbon-14. As there was no decomposition in the nutrient solution these figures imply that the plant roots had absorbed both iron and iron chelate. Later results showed that while the rate of uptake of iron decreased with time, that of the carbon-14 (EDTA) continued steadily. The EDTA liberated by the absorption of iron probably chelated other metals, for example, copper, zinc and manganese, in the nutrient solution. Subsequent absorption of these chelates would explain the steady increase in carbon-14 content and the progressive increase in the ratio of carbon-14 to iron in the plant tops.

This is the first report of experimental evidence that EDTA is broken down during the utilization by plants of the iron chelate, although it has been suggested previously that the iron might be released during breakdown of the chelate in leaves by sunlight[6].

A Lipoprotein Staining Method for Zone Electrophoresis

IN an attempt to overcome some of the well-known disadvantages of the commonly used lipoprotein stains, a new method, based on the use of Schiff's stain after preliminary ozonization, was developed. It does not depend on the use of lipid stains, and, consequently, washing the stain out of the background is not necessary. Furthermore, it can be used equally well on cellulose acetate material and on filter paper.

The electrophoretic separation is performed in the usual manner, but a somewhat larger sample than that used for ordinary protein separation is recommended. When the separation is completed, the strip is dried under a fan or in a hot-air oven at a temperature preferably not exceeding 80° C., and placed in a chamber for ozonization. The ozone can be introduced from an ozonizer or it can be generated chemically inside the chamber. I have been using a barium peroxide–concentrated sulphuric acid method which is both simple and cheap. A small glass container with the barium peroxide powder is placed inside the ozonizing chamber (a large jar or glass tank with a closely fitting lid, the size depending on the number and size of the strips) and a small volume of concentrated sulphuric acid is poured over the barium peroxide. The lid of the chamber is then quickly closed. The necessary amounts of the reagents will vary with the capacity of the chamber. After about 15–30 min. the strip is removed from the ozone atmosphere, rinsed in $N/1,000$ hydrochloric acid, and placed in Schiff's stain (prepared as for glucoprotein staining) until the lipoprotein bands acquire their maximum colour intensity. This usually takes about 5–15 min., but the staining time does not appear to be critical and the strips can be left for longer periods of time. When staining is completed, the strip is transferred into a reducing solution, for example, potassium metabisulphite crystals in $N/10$ hydrochloric acid. A thorough washing in three consecutive reducing baths is essential if the background is to remain colourless. A final wash in plain $N/10$ hydrochloric acid is recommended. The strip is then blotted and dried at room temperature. It was found that instead of the reducing bath, a 2–3 per cent aqueous nitric acid solution can be used with almost equally satisfactory results, with the advantage of not having to prepare the reducing solution each time and avoiding the irritating smell of sulphur dioxide. As an alternative to the preliminary exposure to ozone, quite satisfactory results can also be obtained by immersing the strip for about 20 min. in a 2–3 per cent solution of iodic acid, or in a 5 per cent aqueous potassium iodide solution which has been left standing in the light for a few days acquiring a very pale yellow tinge. It should then be kept in the dark. The intensity of colour of the lipoprotein bands, however, will not reach that obtained after ozonization.

The results are shown in Figs. 1 and 2. In normal human serum two lipoprotein fractions are usually seen, but it should be noted that on cellulose acetate the main lipoprotein fraction of the serum travels with α_2 mobility and not with the β fraction as on filter paper. The stained bands obtained by this method coincide exactly with those obtained with any of the conventional lipid stains such as sudan black. This can be seen by comparing the bands with parallel lengths from the same strip by the ozone – Schiff and sudan black methods respectively (Fig. 1).

PHYSIOLOGY

Some Pharmacological Actions of D-Lysergic Acid Methyl Carbinolamide

D-LYSERGIC acid methyl carbinolamide, $C_{18}H_{21}N_3O_2$, is a new alkaloid produced by a strain of *Claviceps paspali* Stevens and Hall. Arcamone, Bonino, Chain, Ferretti, Pennella, Tonolo and Vero[1] isolated the new alkaloid from submerged cultures and determined its structure. I have now investigated some of the pharmacological actions of the new alkaloid.

D-Lysergic acid methyl carbinolamide was kindly supplied to me by Prof. E. B. Chain. Freshly prepared aqueous solutions of the maleate salt ($C_{18}H_{21}N_3O_2\ C_4H_4O_4$) were used in my experiments.

The intravenous *LD*50 of the new alkaloid was approximately 150 mgm./kgm. for mice and 0·75 mgm./kgm. for rabbits. Before death, the mice showed periodic convulsions of a clonic type, erection of the hairs and excitability. At doses of 50–100 mgm./kgm. it produced only this peculiar symptomatology: the mice stood upright and pressed on each other's noses and chattered their teeth. In rabbits, an injection into the ear vein in doses of 0·1–1 mgm./kgm. produced dilatation of the pupil, excitability or convulsions of a clonic type. The ears became pale and cold with intense vaso-constriction. The toxicity of the alkaloid to rabbits seemed to depend on its power of raising the body-temperature in this species. In rabbits the similarity between the effects of the new alkaloid and ergometrine were particularly striking, but ergometrine was less toxic to rabbits (the approximate intravenous *LD*50 of ergometrine was 3·5 mgm./kgm.).

D-Lysergic acid methyl carbinolamide induced, in low concentrations (minimum active concentration 0·1–1 μgm./ml.), a contracture in the isolated uterus of the virgin guinea pig. There was a satisfactory dose/response relationship. This contracture was very similar to that produced by ergometrine maleate, which, however, was 1–2 times more potent.

On the rabbit uterus *in situ* both alkaloids produced a prompt contraction and increased rhythmic activity of the uterus. For ergometrine the minimum active dose by intravenous route was 0·1–0·3 mgm./kgm. and for the new alkaloid 0·2–0·5 mgm./kgm. The actions of both alkaloids lasted some minutes, and owing to the favourable circumstance that the interference between the effects of the two alkaloids was negligible, it was possible to test them on the same preparation. Ergometrine was 1–2 times more potent than the new alkaloid.

On the isolated seminal vesicles of the guinea pig, the new alkaloid was approximately 200 times less potent than ergotamine tartrate as an adrenergic blocking drug.

Rabbits anæsthetized with urethane supported doses of D-lysergic acid methyl carbinolamide which would have killed unanæsthetized animals. Rapid intravenous injections of small doses (0·1–0·2 mgm./kgm.) of the new alkaloid caused an evanescent decrease or a small increase of blood pressure; with higher doses (0·3–0·5 mgm./kgm. and more) the blood pressure increased moderately without showing any dose/response relationship. Ergometrine maleate seemed to be less active on blood pressure, and there was no significant change of blood pressure with 0·3–0·5 mgm./kgm.

The new alkaloid was without effect, when given in small doses, on the blood pressure of cats anæsthetized with chloralose. Higher intravenous doses (0·1–0·3 mgm./kgm.) caused a sustained hypotension of long duration and a moderate decrease of heart-rate. The respiration of rabbits and cats was depressed by small doses of the new alkaloid; cats seemed to be less resistant than rabbits. In cats, 0·01 mgm./kgm. of the new alkaloid caused broncho-constriction and contraction of the nictitating membrane of long duration.

The new alkaloid had no action on isolated rabbit auricles at doses up to 100 μgm./ml.

In summing up, the new naturally occurring alkaloid D-lysergic acid methyl carbinolamide has powerful ergometrine-like oxytocic actions and weak ergotamine-like adrenergic blocking actions. It must be included, on the basis of pharmacological evidence, in the ergometrine group of ergot alkaloids. Ergometrine, however, is less toxic and more active than the new alkaloid. Some of my results suggest that it could have a lysergic acid diethylamide-like activity, but this hypothesis must be checked by experiments on humans.

Full details of this work will be published elsewhere.

Repression and De-repression of Enzyme Synthesis as a Possible Explanation of some Aspects of Drug Action

ACCORDING to recent theories, the induction of enzyme synthesis occurs as a result of the displacement from an enzyme-forming system of a natural repressor[1]. For example, the synthesis of alkaline phosphatase by *E. coli* is normally repressed by inorganic phosphate[2]. De-repression occurs when there is only a small amount of inorganic phosphate in the medium. The repressor theory is in good agreement with most of the observations which have been made on enzyme-inducing systems. The inducer need not be a substrate for the enzyme which is formed, nor need it serve as a template for the formation of new enzymes[1].

While this phenomenon is best known from work with bacteria, examples of the de-repression of various mammalian enzymes have also been reported[3]. Especially interesting are instances of the apparent de-repression of enzymes which metabolize certain drugs and carcinogens. There is an enzyme system in liver microsomes which, in the presence of reduced triphosphopyridine nucleotide and oxygen, can carry out a number of 'detoxifying' reactions. These include: the hydroxylation of aromatic rings, the O-dealkylation of aromatic ethers, the N-dealkylation of substituted amines, reductive cleavage of diazo groups, and the oxidation of alkyl side-chains. There are probably several different enzymes involved, but they all have similar requirements, and all are inhibited by diethylaminoethyl-diphenylpropyl acetate (*SKF 525-A*)[4].

Many of the known substrates of the reduced triphosphopyridine nucleotide – oxygen – microsomal system, and some compounds of similar structure, can produce marked de-repression of various enzymatic activities when injected into young rats. Examples of such increased enzyme synthesis are: increased hydroxylation of 3,4-benzpyrene[5] and 2-acetylaminofluorene[6]; and increased N-demethylation and reductive cleavage of azo dyes[7,8]. Actual enzyme synthesis is believed to be taking place in these instances because treatment with ethionine prevents such increases in enzyme activity and this inhibition is overcome by methionine.

Another enzyme system which can be de-repressed by the same treatment is that which converts glucose to glucuronic acid and ascorbic acid. This de-repression leads to striking increases in excretion of ascorbic acid and glucuronic acid by treated rats [8–10]. There is also increased conversion of glucose-^{14}C to glucuronic acid and ascorbic acid[9]. The increased excretion of ascorbic acid appears considerably later than the rise in activity of the reduced triphosphopyridine nucleotide–oxygen–microsomal system, and may perhaps be a secondary response to increased synthesis of glucuronic acid. It can be pointed out that the detoxified products of the microsomal system are usually further metabolized as glucuronides[4]. While barbital is not metabolized by the microsomal system which 'detoxifies' other barbiturates, it can nevertheless produce the same type of de-repression[8].

It may well turn out that the physiological substrates of both the 'detoxifying' microsomal system and the glucuronide-synthesizing system are actually steroids. The injection of 3-methyl cholanthrene or related carcinogens increases the hepatic metabolism of hydrocortisone[11]. Compounds such as methyl cholanthrene, benzpyrene and dibenzanthracene could act as de-repressors by virtue of their similarity to natural steroid repressors. These carcinogens are known to potentiate the biological activities of steroids[11]. There is a sex difference in the activity of the microsomal system in adult rats. This produces marked differences in the rates of detoxification of hexobarbital[4] and the N-demethylation of morphine[12]. Such sex differences can be altered in either direction by treatment with sex hormones, and this may represent an example of repression and de-repression by steroid hormones.

Examples of drug-induced enzyme repression can also be found. An outstanding case is the striking decrease in N-demethylase activity found by Axelrod in the liver microsomes of rats made tolerant to morphine[13]. This was suggested as a model system for the phenomenon of drug tolerance as seen in narcotic addiction[13,14]. It was postulated by Axelrod that continued exposure to morphine might lead to a similar inactivation of a receptor site in the central nervous system. This theory does not explain the development of physical dependence as manifested by the appearance of withdrawal symptoms.

The concept of drug-induced repression of enzyme synthesis can be used to formulate a scheme which serves to explain the features of tolerance to, and physical dependence on, narcotics like morphine as shown in Fig. 1.

According to this scheme, morphine can act at two sites. By inhibiting at site *A* the action or synthesis of a neurohormone required for proper functioning of the central nervous system, it can bring about its characteristic effects of depression of the central nervous system, analgesia and sedation.

On repeated administration (or on a few treatments with very high doses[14]) morphine also begins to act at site *B*, causing de-repression of the system which makes the neurohormone-synthesizing enzyme. This would increase the amount of neurohormone acting on the central nervous system. Tolerance to the depressant effects of morphine develops because more morphine is now required to depress the central nervous system.

Another way in which the same result could be achieved is also indicated in Fig. 1. Instead of acting at site *B*, morphine could increase the concentration of neurohormone by repressing, at site *C*, the synthesis of an enzyme which destroys the neurohormone. Such a repression would be similar to the repression by morphine of the synthesis of morphine N-demethylase.

When morphine is afterwards withdrawn, the increased amount of neurohormone is no longer 'neutralized' by morphine, and the result is the excitation of the central nervous system typically observed as withdrawal symptoms. This creates an apparent physical dependence on the narcotic, since these symptoms are readily controlled by a resumption of morphine administration. The withdrawal symptoms gradually diminish in intensity as the concentration of neurohormone returns to normal and tolerance also disappears. The morphine antagonist N-allylnormorphine can precipitate withdrawal symptoms in an addicted animal by competing with morphine for site *A* and thus unmasking the effects of an increased concentration of neurohormone.

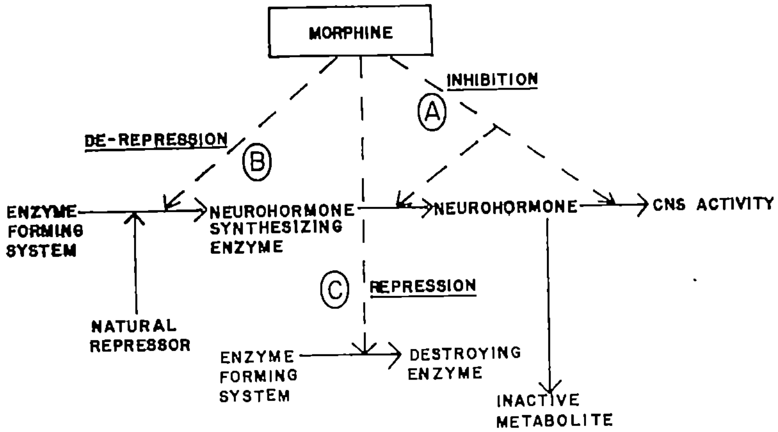

Fig. 1. Hypothetical scheme for explaining some of the actions of morphine in terms of repression and de-repression of enzyme synthesis

The examples given here indicate that the concept of repression and de-repression of enzyme synthesis may prove useful in understanding how drugs can modify the biochemical mechanisms which make for a normal homœostatic condition in the mammalian organism.

Glutamic Oxaloacetic Transaminase Activity in Different Zones of the Ventricular Muscle of the Dog

OF the tissues of several animal species the myocardium has the highest concentration of glutamic oxaloacetic transaminase (GOT)[1-3]. Distribution of this enzyme in several zones of the cardiac muscle has received but scant attention in the literature. However, it has been shown that the dog's left ventricle has a higher GOT activity than the right one[4], and a similar difference has been described for the concentration of adenosine triphosphatase and succinic dehydrogenase[5]. On the other hand, Jennings, Kaltenbach and Smetters failed to note significant differences in the left ventricle of the dog between the GOT activity of the posterior papillary muscle, the left ventricle immediately beneath, and the anterior superior septum[6]. The present observations show that GOT activity of the myocardium is not uniform, and that there are significant differences in dogs among several zones of both ventricles.

Six male and four female adult mongrel dogs, weighing between 5 and 8 kgm. were anæsthetized with sodium pentobarbital (33 mgm./kgm.); the heart was removed and two small muscle samples from each one of the following zones of the ventricles were excised: (*a*) outer surface from the middle part of the free wall (to be called left epicardium); (*b*) inner surface of the free wall beneath the removed epicardial zone (to be called left endocardium); (*c*) muscle lying between the two formerly described (to be called mesocardium); (*d*) inner endocardial layers from the middle part of the left side of the septum (to be called septum). In six further dogs (four male and two female), (*a*) and (*b*) were removed simultaneously with (*e*) outer surface from the middle part of the right free wall (to be named the right epicardium) and (*f*) inner ventricular surface beneath the previous one (to be named right endocardium). Twenty mgm. were immediately weighed from each sample in a torsion balance to the nearest mgm., and cut in 10-µ sections with a freezing microtome. The enzyme was extracted by incubation at 2–4° C. for 30 min. in phosphate buffer at *p*H 7·4. Enzyme activity was determined by a modification of the technique of Cabaud, Leeper and Wroblewski for blood serum[7]. Incubation was carried out at 25° C. for 20 min. with D,L-aspartic and α-keto glutaric acids as substrate. All observations were performed 'blindly' in duplicate; results were compared with Student's t test according to Fisher and Yates's Tables[8].

The results expressed in µmoles of pyruvate liberated per mgm. of wet tissue under the stated conditions are shown in Tables 1 and 2. Error of the method ($e = \frac{Sm \times 100}{\bar{X}}$; where Sm = standard error of the mean; $\bar{X}$ = mean of observations) was found to be ± 0·81 per cent on 16 duplicate determinations and performed on one ventricular sample. As can be seen the GOT activity of the left endocardium (1·126 ± 0·041 *S.E.*) is higher than that of the left epicardium (0·817 ± 0·036). The enzymatic activity of the mesocardium (0·946 ± 0·029) lies between both, while in the septum (0·971 ± 0·027) it is lower than in the left endocardium. No significant differences in enzymatic activity are noted between the septum and the mesocardium. On the other hand, the right epicardium has a higher concentration than the right endocardium (1·205 ± 0·088 and 0·949 ± 0·063, respectively).

The high concentration of the GOT in the myocardium[1–3] may indicate that this enzyme has an important bearing on cardiac metabolism. Nevertheless, very little is known about the relationships existing between such an enzymatic activity and the main manifestations of cardiac activity, namely, bioelectric and contractile phenomena. Transamination reactions provide anaerobically certain metabolites (oxaloacetic and pyruvic acids, for example) which are aerobically oxidized stepwise by mitochondrial enzymes of the Krebs cycle, liberating a great amount of energy. In this connexion it has been pointed out that the cardiac muscle can use these metabolites to supply a large part of the energy required to support the contractile activity of the myocardium[9].

Table 1. GOT ACTIVITY IN DIFFERENT ZONES OF THE LEFT VENTRICLE

Zone	No. of determinations	GOT in µmoles of pyruvate/ mgm. of wet tissue
(1) Epicardium	20	0·817 ± 0·036
(2) Endocardium	20	1·126 ± 0·041
(3) Mesocardium	16	0·946 ± 0·029
(4) Septum	16	0·971 ± 0·027

t 1 vs. 2 = 5·722, $P < 0·001$; t 1 vs. 3 = 2·866, $P < 0·01$; t 1 vs. 4 = 3·500, $P < 0·01$; t 2 vs. 3 = 3·660, $P < 0·001$; t 2 vs. 4 = 3·875, $P < 0·001$; t 3 vs. 4 = 0·833.

Table 2. GOT ACTIVITY IN DIFFERENT ZONES OF BOTH VENTRICLES

Zone	No. of determinations	GOT in µmoles of pyruvate/ mgm. of wet tissue (mean ± standard error of the mean). Right ventricle	No. of determinations	GOT in µmoles of pyruvate/ mgm. of wet tissue (mean ± standard error of the mean). Left ventricle
(1) Epicardium	11	1·205 ± 0·088	11	0·956 ± 0·061
(2) Endocardium	12	0·949 ± 0·063	10	1·201 ± 0·077
t 1 vs. 2		2·370, $P < 0·05$		2·525, $P < 0·01$

It is probable that differences in enzymatic activity may be related to functional differences of the myocardium, since metabolic activity determines the fundamental properties of the cardiac fibres. Our findings indicate that the free wall of the left ventricle shows an enzymatic concentration that falls progressively from the endocardium to the epicardium. Furthermore, the samples from the left endocardial surface of the septum show a lower enzymatic activity than those from the endocardium of the left ventricular free wall. On the other hand, in the right ventricle the epicardium has a higher enzymatic concentration than the endocardium. When it is considered that some of the bioelectric properties, for example, rate of repolarization, are not the same in different zones of the myocardium[10], it seems worthwhile to study the relationships, if any, of these properties and transamination activity.

We gratefully acknowledge critical revision of the manuscript by Dr. Bernardo A. Houssay and Dr. Virgilio G. Foglia.

Inhibiting Effect of 2 : 4-Dinitrophenol on Calciferol-induced Metastatic Calcification in the Rat

PREVIOUS investigations by Trout[1] and by us[2] indicate clearly that the deposition of mineral in the aortæ of calciferol-intoxicated rats continued long after cessation of administration of this compound and after the blood calcium-level had returned to normal. It appears that, once initiated, this process follows an irreversible course, at least in the aorta, since even 160 days after the initial insult there was no evidence of a reduction in the mineral content of the aorta. Attempts to inhibit calciferol-induced calcification of the aorta by the simultaneous administration of papain (which reduces the mucopolysaccharide content of the aorta) were unsuccessful[3].

Since the calcification is accompanied by a large increase in aortic phosphorus content, it was decided to investigate the effect of 2 : 4-dinitrophenol (DNP) on the action of calciferol administered simultaneously; for it has been shown by Whitehead and Weidman[4] that DNP *in vivo* inhibits the synthesis of adenosine triphosphate, as measured by the incorporation of phosphorus-32, and also the incorporation of the isotope into the bone salt of kitten cartilage. Gutman and Yü[5] found that calcification *in vitro* was markedly inhibited by 2 : 4-dinitrophenol at 10^{-4} *M* concentration. Whitehead and Weidman suggested that the relationship between phosphorus-32 incorporated into bone salt and adenosine triphosphate is that the latter is required to initiate the formation of a primary seed which acts as a nucleus for the subsequent deposition of bone salt.

Accordingly, 20 male Wistar strain rats, initially weighing approximately 250 gm., were divided randomly into four groups of five. Group I was given, twice daily, intraperitoneal injections of 3 ml. of 0·9 per cent sodium chloride solution for twenty days. Group II received identical saline injections, together with calciferol (a total of 100,000 units/kgm. body-weight) given orally, in daily doses, as a solution in arachis oil from day 6 to 10 inclusive. Group III were given, twice daily, injections of 3 ml. of a saturated solution of DNP in 0·9 per cent sodium chloride, while Group IV received the same injections together with calciferol orally as in Group II. On day 20 the animals were killed and the aorta, lungs and stomach dissected out. The tissues were dehydrated with acetone, defatted with ether–alcohol (1 : 1 v/v) and dried to constant weight at 100° C. A second series of animals received the same treatment, but were killed on day 9 of the experiment, that is, 4 days after starting calciferol treatment, and bled from the heart; the serum was analysed for calcium and inorganic phosphorus. Differences between means were assessed by the Mann–Whitney *U* test, using the 5 per cent level of significance.

Table 1 shows the mean aortic dry weight and the calcium and phosphorus contents of the aortæ. Calciferol treatment resulted in an approximately two-and-a-half-fold increase in mean aortic dry weight, similar to that previously found by us[2]. We have found this increase in weight to be due largely to the increased mineral content of the aortæ (see below). For this reason, the results for calcium and phosphorus are expressed in mgm./aorta. It will also be seen from Table 1 that DNP, administered simultaneously with calciferol, significantly reduced the effect of calciferol on total aortic weight, although DNP alone had no effect at all on the aortic dry weight.

Table 1. DRY WEIGHT AND MINERAL CONTENT OF RAT AORTÆ

Group	Treatment	Dry fat-free weight (mgm.)	Calcium (mgm./aorta)	Phosphorus (mgm./aorta)	Calcium/phosphorus ratio
I	Saline only	16·7 ± 1·2*	0·21 ± 0·06	0·07 ± 0·01	3·0 : 1
II	Saline + calciferol	48·8 ± 5·5	6·23 ± 0·91	2·30 ± 0·33	2·7 : 1
III	DNP only	16·7 ± 1·0	0·11 ± 0·01	0·08 ± 0·01	1·4 : 1
IV	DNP + calciferol	28·1 ± 4·0	2·88 ± 1·04	1·15 ± 0·31	2·5 : 1

* Mean ± *S.E.*

Calciferol treatment also resulted in significant increases in both calcium and phosphorus contents of the aorta; DNP alone had no effect on these constituents, but when given simultaneously with calciferol, significantly reduced the degree of mineralization induced by calciferol, by approximately one-half. The calcium–phosphorus ratio of the aortæ tended to be reduced in the two groups receiving DNP injections, but, due to wide variations in individual values, the differences were not significant.

Results similar to those from aortæ were obtained for lung and stomach; for calciferol produced significant increases in the calcium and phosphorus contents of these organs as well[2] and DNP, given simultaneously, reduced this effect.

The results of the serum calcium and phosphate determinations showed that calciferol markedly increased both these serum constituents (calcium–phosphorus product raised to 125 compared with control value of 77). However, despite its marked effects on tissue mineralization, DNP given simultaneously with calciferol did not affect the increases in serum calcium and phosphorus induced by calciferol.

Hence it would appear that the inhibiting effect of DNP on the calcification induced by calciferol is not mediated via any overt action on blood calcium or phosphate-levels. It would thus seem to exert some direct effect on the tissues, although an indirect action, via the endocrine system, for example, parathyroids, cannot be ruled out at present.

A full account of this work will be published elsewhere. It was conducted with the aid of grants from the Nuffield Foundation, the Wellcome Trust, the South African Council for Social and Industrial Research, and Mr. Ronald Cohen.

Function of the Hypophysis–Thyroid System in the Rabbit Fœtus with Regard to Cholesterol Metabolism

THE experimental studies of Jost[1] and Hwang and Wells[2] have demonstrated the functional interrelationship of the pituitary and thyroid in the rabbit and rat fœtus. Rumph and Smith[3] showed that the thyroid of the 90-mm. pig fœtus contains a substance which would induce metamorphosis in the hypophysectomized tadpole. Geloso[4] demonstrated the presence of thyroid hormones in the blood of the rat fœtus. Jost and Picon[5] showed that fœtal thyroidectomy resulted in an increase in total body fat in the rabbit fœtus. Bearn[6] found an increase in liver fat following hypophysectomy by decapitation in the rabbit fœtus, and correlated this with the increase in the fat content noted in human anencephalic fœtuses. These experiments can be taken to indicate that the fœtal thyroid is capable of function, and that its function is regulated by the fœtal pituitary.

It is well known that there is in both adults and in infants a close relationship between thyroid function and cholesterol metabolism. A rise in blood cholesterol has been reported in hypothyroidism[7] and in cretinism[8]. It was therefore decided to investigate the role of the pituitary and thyroid of the rabbit fœtus in the regulation of cholesterol metabolism.

Nineteen rabbit fœtuses were decapitated by a modification of the method described by Jost[9]. Nine fœtuses were decapitated through the neck to remove the thyroid as well as the pituitary, and ten were decapitated through the mouth to preserve the thyroid. The operation was performed between days 21 and 23 following witnessed mating, and the fœtuses were recovered after seven days of further intrauterine development; 53 litter mates were used as controls.

The cholesterol-level of the blood was determined blind by the method described by Abell *et al.*[10], and the results expressed in mgm. per 100 ml. As used in this laboratory, the method has a standard error of blind duplicates of 8·3 mgm. The results are summarized in Table 1.

Table 1. CHOLESTEROL-LEVELS IN SERUM OF DECAPITATED AND CONTROL FŒTUSES

Fœtuses	Age at investigation	No.	Mean serum cholesterol (mgm./100 ml. ± S.E.)
Low decapitation (at 21–22 days)	28–29 days	9	142 ± 5·2*
Litter mate controls	28–29 days	29	87 ± 2·9*
High decapitation (at 22–23 days)	29–30 days	10	156 ± 6·5*
Litter mate controls	29–30 days	24	97 ± 4·2*

* These differences are significant, $P < 0.001$.

There is a variability in the level of blood cholesterol from one litter to another, but the level in each of the control fœtuses from a single litter shows little variation.

The decapitated fœtuses all showed a significant rise in blood cholesterol, even in those fœtuses in which the thyroid was left behind and only the pituitary removed.

These preliminary results indicate that the fœtal pituitary and thyroid play a part in the cholesterol metabolism of the fœtus. In addition, they indicate that maternal thyroid hormones and maternal thyrotropic hormone do not compensate for the absence of fœtal thyroid and pituitary hormones in the rabbit.

Rate of Anaerobic Glycolysis versus Structure in Pork Muscle

THE *p*H of pork musculature after cessation of post-mortem glycolysis (ultimate *p*H) has long been known to be decisive for structure and water-holding capacity of the muscle. Recent observations[1,2] have shown that considerable variation in structure of muscle with the same ultimate *p*H may be recorded. The rate of the post mortem *p*H fall was found to be of considerable importance.

The investigations which are briefly reported here were facilitated with a *p*H meter (Radiometer model No. 31; electrode-elector type *ELS*31; electronic recorder type 153, Honeywell) for continuous and simultaneous *p*H and temperature recordings. Six *p*H electrode pairs (glass electrodes *G* 2326, calomel electrodes 4116) were inserted in representative muscles and permitted to remain in position from 1 to 24 hr. post mortem. Careful tests have not revealed any indications of artefacts arising from this procedure. The carcasses from 20 Danish Landrace pigs (85–95 kgm.) were used in this work. The continuous recordings from these carcasses depict at least four distinct types of post mortem *p*H patterns: (1) A slow gradual decrease to an ultimate *p*H of 5·7–6·3. (2) A gradual decrease to approximately 5·7 at 8 hr. with an ultimate *p*H of 5·3–5·7. (3) A relatively rapid decrease to approximately 5·5 at 3 hr. with an ultimate *p*H of 5·3–5·6. (4) A sharp, significant decrease to a *p*H of approximately 5·1 at 1½ hr. and a subsequent elevation to 5·3–5·6.

The anaerobic glycolysis of the type 4 compared to the type 2 *p*H pattern and the effect on the tissue of the longissimus dorsi muscle will be briefly elaborated.

A Radiometer *p*H meter (model 24) was used to determine *p*H values at 15-min. intervals to the 1-hr. period while the carcasses were in the slaughter line. Afterwards the carcasses were transferred to a 3° C. atmosphere for continuous recordings (*p*H

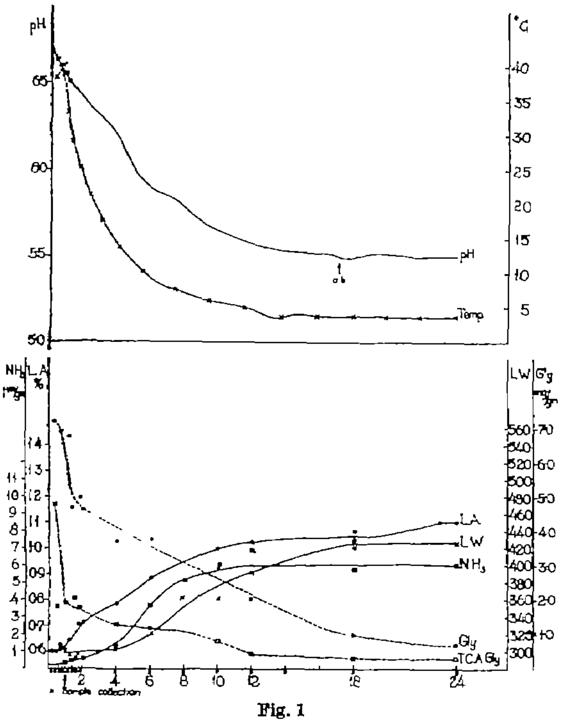

Fig. 1

and temperature) from 1 to 24 hr. Thermocouples and electrodes were uniformly placed in the muscle in the area of the second lumbar vertebra. Samples of the longissimus dorsi from the twelfth rib to the last lumbar vertebra of the opposite side were secured, for analysis, at various intervals as indicated in Fig. 1.

The results in Fig. 1 show the features of a slow rate of anaerobic glycolysis (type 2), those in Fig. 2 depict the rapid rate of the type 4 muscle. In the type 4 muscle *p*H decreased to 5·1–5·2 in 1½ hr., while the temperature was 36–40° C. In the type 2 muscle the lowest *p*H around 5·5 was not reached until the temperature approximated 4° C. The difference in the rate of *p*H fall was due to difference in rate of anaerobic glycolysis as illustrated by the glycogen[1] and lactic acid[3] determinations. The type 4 muscle initially contained a relatively high percentage of protein-bound glycogen. This may be seen by comparison of the amounts of glycogen soluble in trichloracetic acid in a single rapid extraction[4,5]. The liberation of ammonia[6] and depletion of labile phosphate (7'P) (ref. 7) suggest that rigor mortis occurred during the first 30–45 min. in the type 4 muscle, compared to 4–6 hr. post mortem for the type 2 muscle. It was furthermore noticed that the decrease in temperature during the first 2 hr. was comparatively slow in the type 4 muscle, apparently due to the heat of the rapid glycolytic reactions.

The effect of *p*H and onset of rigor mortis on the water-holding capacity of the tissue is depicted by the 'loose-water' (LW) number which gives the amount of water in mgm. which can be pressed out of 1 gm. meat under standardized conditions[1]. In the type 4 muscle these numbers rise very sharply to high values and the meat assumed a pale colour. These changes *suggest partial denaturation of the meat proteins*[1].

The sharp pronounced elevation in the type 4 *p*H curve appears connected to partial denaturation of the muscle proteins. In this context it is interesting to note that the proteins of the type 4 muscle show increased affinity for safranine and orange *G* dyes which have been used to determine acidic and basic groups[8]. Furthermore, these proteins bind increased amounts of congo red dye, which is regarded as a sign of denaturation[9]. Average results are reported in Table 1.

Table 1. DYE-BINDING PROPERTIES (24-HR. SAMPLES)

	Type 2	Type 4
Orange *G**	13·94	17·70
Safranin*	14·44	18·71
Congo red†	8·40 (7·79)‡	9·13 (7·31)‡

* Equiv. per 10^4 gm. protein.
† Mgm. dye-bound/100 mgm. protein.
‡ 15 min. post mortem.

Further support for the importance of the acid–temperature relationship has been shown by repeated trials with sections of the longissimus dorsi muscle. These sections were removed from the carcasses, immediately post mortem, and held at varied temperatures. The sections which were retained at 37° C. for 1½ hr. displayed the characteristics of type 4. Conversely, those which were chilled rapidly seemingly avoided the extreme drop in *p*H and were normal in colour and structure.

Preliminary observations of biopsy samples from six Danish Landrace pigs which ultimately showed the type 2 and type 4 *p*H curves are shown in Table 2. Three weeks prior to slaughter the pigs were anæsthetized with trichloro-ethylene and biopsy samples were removed from the lumbar region of the longissimus dorsi muscle[10]. The biopsy samples of pigs which ultimately showed the type 4 *p*H pattern contained greater total glycogen, higher percentage of protein-bound glycogen and faster phosphorylase activity. Similarly, these pigs possessed a smaller pyruvic acid pool and a greater lactic acid

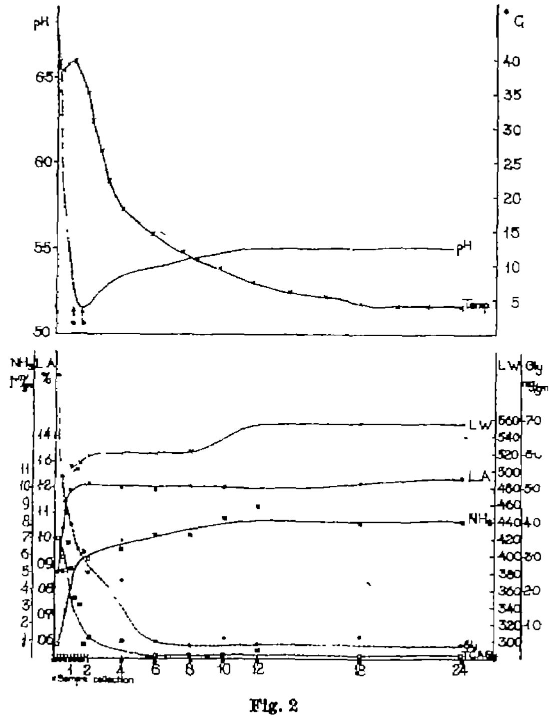

Fig. 2

Table 2. GLYCOLYTIC COMPONENTS (BIOPSY SAMPLES)

	Type 2	Type 4
Total glycogen (mgm./gm.)	4·02	7·45
Glycogen (acid-soluble) (per cent of total)	49 64	39 39
Pyruvic acid (mgm. per cent)	2 80	1·18
Lactic acid (per cent)	0·29	0 52
Phosphorylase (mgm. glycogen/gm. tissue/30 min.)	11·38	15 49

concentration. Results to date also suggest that lactic acid is converted to pyruvic acid, *in vivo*[11], at a slower rate in muscles with the type 4 *p*H pattern.

It is hoped to publish a complete account of these investigations elsewhere. One of us (E. J. B.) is grateful to Oscar Mayer and Co., Madison, Wisconsin, for their support (on leave from University of Wisconsin) for the duration of this work.

HÆMATOLOGY

Deformation of Red Cell Shape induced by *Vipera palestinae* Venom *in vivo*

IT has been previously reported[1] that *Vipera palestinae* venom causes *in vitro* disk-sphere transformation of red blood cells in the presence of plasma without producing hæmolysis. This phenomenon could be reversed by suspending the spherical red cells in normal plasma. In the present work an attempt was made to establish whether similar changes of red blood cells occur also *in vivo*.

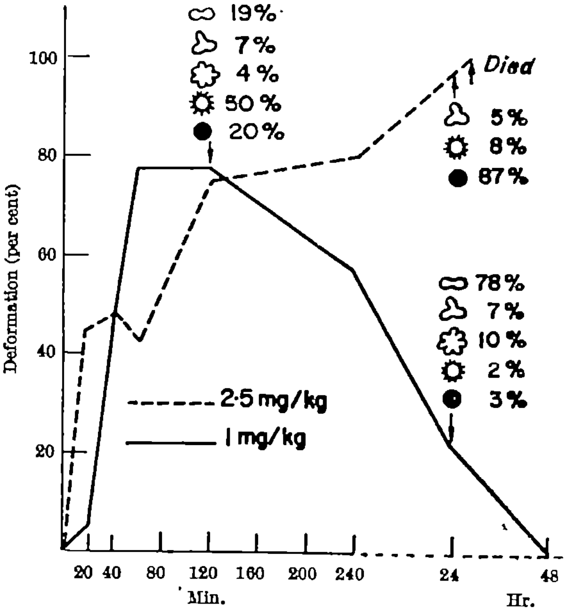

Fig. 2. *In vivo* deformations of erythrocytes of unanæsthetized rats after intramuscular injection of *Vipera palestinae* venom

Sublethal and lethal doses of venom were injected by the intramuscular and intravenous routes to rabbits and rats anæsthetized with urethane or pentobarbital sodium as well as to non-anæsthetized animals. A drop of rat blood from the tail tip was introduced directly into 0·5 ml. of 0·5 per cent osmium tetroxide solution in phosphate buffered isotonic sodium chloride, *p*H 7·2. Rabbit blood samples were drawn from the ear vein or from the jugular vein. Blood cells were examined under the phase contrast microscope, or, after a single washing of the fixed cells with distilled water, in aluminium shadow-cast smears[2], in which the various shapes of 200 erythrocytes were counted. The degrees of deformation observed were classified as follows: (1) normal bidiscoids; (2) slightly deformed cells (the bidiscoid form no longer recognizable, but not yet crenated); (3) grossly crenated cells; (4) finely crenated spheres of small diameter; (5) spheres of small diameter.

In unanæsthetized non-venom-treated animals 95–100 per cent of the red cells were bidiscoid. The majority of the anæsthetized non-venom-treated animals, however, showed some degree of deformation of the red blood cells, ranging from practically 0 to 37 per cent slightly deformed erythrocytes (degree 2). After intramuscular injection of venom the degree of deformation as well as the percentage of cells with a higher degree of deformation increased with time. With increasing doses the changes occurred more rapidly.

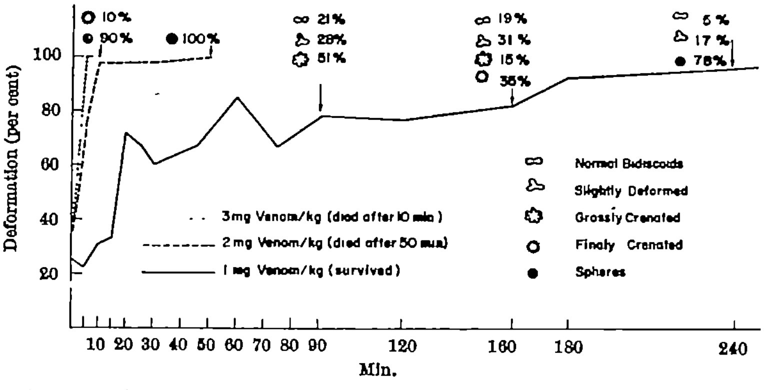

Fig. 1. *In vivo* deformations of erythrocytes of anæsthetized rabbits after intramuscular injection of *Vipera palestinae* venom

Fig. 1 presents the progressive deformation of erythrocytes of anæsthetized rabbits injected intramuscularly with sub-lethal and lethal doses of venom. The curves represent the percentage of deformed cells, counted after various time-intervals.

Sublethal doses (up to 1 mgm./kgm. intramuscular) induced maximum deformation after about 3 hr. Thereafter reversion to the normal bidiscoid shape began, reaching completion after 6–48 hr. Lethal doses produced rapid progressive deformations, culminating in complete sphering; the higher the venom dose, the earlier this occurred.

Fig. 2 represents the findings in unanæsthetized rats. When a lethal dose (2·5 mgm./kgm. intramuscular) was injected the deformation reached a maximum shortly before the animal died, while no ghosts were observed. This is in agreement with the venom having no direct hæmolytic activity *in vitro*[3]. On the other hand, injection of the venom of *Naja naja* (cobra), known to have direct hæmolytic activity, did produce ghosts. After administration of a sublethal dose (1 mgm./kgm.) reversion of the deformation occurred and was completed after 24–48 hr.

In view of these results it is suggested that the severity of *Vipera palestinae* snake bite might be judged by the study of the degree of deformation of the red cells in a sample of peripheral blood, fixed in osmium tetroxide.

Di^a, Js^a and V Blood Groups in South and South-East Asia

The red-cell antigens, Di^a and Js^a, are among those of special interest as genetic markers in human populations because they attain reasonable frequency in at least one of the major divisions of the human race, but are rare or entirely absent in all others. The Di^a blood-group factor is restricted to American Indians and Mongoloid populations[1] or those of mixed American Indian ancestry[2]. The more recently discovered Js^a antigen has been detected so far only in the blood of Negroes or of those with the possibility of Negro ancestry[3]. A third blood-group, the Rh antigen V, also may be highly restricted, since it is found most commonly in the blood of Negroes, and only rarely in Caucasians, American Indians or Orientals[4]. The distribution of none of these three antigens, however, has been studied widely in Asiatic populations. We consider it worth while, therefore, to present the results of such a study.

Samples were collected in the field into 'Bayer' venules and allowed to clot. They were sent as soon as possible in ice-cold containers to Perth and were generally tested not more than seven days after collection. Adults only were sampled. Although attempts were made to secure blood from unrelated individuals, this was not always possible in the case of relatively small breeding populations, such as the Veddahs in Ceylon, the Irulas and Kurumbas in south India and the Maeo and Yeo tribes in northern Thailand.

All tests were carried out using a standard anti-human globulin reagent prepared at the Commonwealth Serum Laboratories. The reactions were carefully controlled, and only cells were tested which gave a completely negative reaction against the anti-human globulin reagent alone. To check the validity of the Js^a and V reactions cells aged to the same degree were tested with anti-Js^a and anti-V by Dr. Eloise Giblett in Seattle, and known Js^a + ve and V + ve cells sent from Seattle were confirmed by similar reactions in Perth.

The results, as set out in Table 1, show no Js^a + ve or V + ve reactions for 1,274 individuals from twelve ethnic groups in south and south-east Asia. Similarly there were no Di^a + ve individuals among the Veddahs of Ceylon, the Veddoid Irula and Kurumba tribes of South India or among the Tamil, Singhalese, Punjabi or Pathan populations sampled. Di^a + ve reactions were found, however, in Malays, Thais in Bangkok and Chiengmai, the Maeo and Yeo tribes in northern Thailand and the Oraon tribe from the Chota Nagpur Plateau in India. Attention should be directed to the single Indian in the sample from Perlis in northern Malaya who gave a Di^a + ve reaction. This person was born in Malaya, and it is possible that there had been some admixture of Malayan blood which introduced the Di^a antigen in this case.

Table 1. Number of Di^a+ve, Js^a+ve and V+ve Reactions in Blood from Various Populations in South and South-East Asia

Ethnic group	No. tested	Di^a+ve	Js^a+ve	V+ve

Malaya				
Malays	40	1	0	0
Indians	131	1	0	0

* Not tested with anti-Di^a.

These results, together with those reporting the absence of Di^a + ve reactions in Australian aborigines and other Pacific Island populations[5], lend support to the view that the Di^a antigen is restricted to people of Mongoloid descent. But if this is true the presence of 5 per cent Di^a + ve individuals among the Oraons of the Chota Nagpur Plateau merits further study. It is possible that there has been a considerable flow of Mongoloid genes into the tribal populations of eastern India, and we hope to publish elsewhere a more detailed analysis of this problem.

The complete absence of the Js^a antigen reactions in the whole of south and south-east Asia, together with its previously reported absence in Caucasian, American Indian and Polynesian populations, supports the view that this antigen is restricted to Negroes. In this connexion its absence in the Irula and

Kurumba tribes, despite the presence among them of a high sickling frequency[4], is of special interest.

Finally, although there has been relatively little study of the distribution of the Rh antigen V, its complete absence in the present investigation is scarcely consistent with the finding of it in low frequency in Oriental, Caucasian and American Indian populations[4]. Because of its low frequency in these populations, however, a much larger series would be needed to exclude its presence in Asian populations with certainty.

We are indebted to Dr. M. Layrisse for supplying anti-Di^a serum and to Dr. Eloise Giblett for supplying anti-Js^a and anti-V sera, and also for assistance in checking Js^a and V reactions. Mrs. E. I. W. Vos gave us valuable technical assistance and many persons assisted in the collection of blood in the field, particularly Drs. R. L. Wickremasinghe, T. Perera, Ali Mohammed Khan, Sommai Sri-ngarm and Sister D. Piljain. The collection of blood samples was made possible by a South East Asia Treaty Organization fellowship to one of us (R. L. K.) and the cost of air transport of samples was defrayed by a grant from the Australian National Health and Medical Research Council. The University of Western Australia also gave generous financial assistance.

PATHOLOGY

Antibodies against Autologous Brain in Rats with Allergic Encephalomyelitis

It is known that rats and other animals injected with nervous tissue emulsified in Freund's adjuvant may develop allergic encephalomyelitis within 2–3 weeks[1–3]. Many of the injected animals, irrespective of whether they develop encephalomyelopathy, produce complement-fixing antibodies which specifically react *in vitro* with homologous or heterologous brain extracts[4–6]. The role of these complement-fixing anti-brain antibodies, however, in the pathogenesis of allergic encephalomyelitis remains unknown.

Paterson[7] has recently shown that allergic encephalomyelitis may be transferred in rats using lymph node cells from donors injected with nervous tissue-adjuvant. In this work, complement-fixing anti-brain antibodies appeared in the sera of many recipients, whether or not they developed allergic encephalomyelitis. For this reason, it could not be concluded whether the lesions in the recipients were caused by anti-brain antibodies released by the lymph node cells following transfer and/or by the transferred lymph node cells themselves.

Direct evidence that circulating antibodies are important in production of allergic encephalomyelitis, by passively transferring the disease using serum, has not been reported. Attempts by various workers (see review by Chase[8]) to accomplish transfer in this manner have failed. Kabat *et al.*[9] suggested that failure to transfer allergic encephalomyelitis by serum might well be due to continual absorption of circulating antibodies by the donor's own (autologous) brain. Indeed, Kabat, Wolf and Bezer[10] demonstrated that injection of autologous brain can induce allergic encephalomyelitis in monkeys. The present work indicates that complement-fixing antibodies induced in rats by nervous tissue-adjuvant can react *in vitro* with autologous brain.

Each of 22 adult Wistar rats received 0·7 ml. of guinea pig spinal cord homogenate in Freund's complete adjuvant, distributed equally among seven intracutaneous sites over the dorsum and ventral neck. The animals were observed daily for clinical signs of encephalomyelitis (for example, hindleg paralysis) for 21 or 25 days. They were then killed by cardiac puncture to obtain sera for complement-fixing tests. At this time, one half of each rat brain was used for preparation of autologous rat brain antigen. The remaining brain and spinal cord of each animal were used for histological studies. Each rat serum was tested for complement-fixing antibodies against autologous brain and homologous brain and kidney antigens. The complement-fixing technique employed and the method of preparing ethanol extracts of these tissues for use as antigens differed from those used previously[4,11] as follows: (*a*) the tissues were not lyophilized prior to extraction with absolute ethanol; (*b*) the complement-fixing reaction mixtures, containing five 50 per cent hæmolytic units of complement, were held at 4–6° C. for 18 hr. before addition of the hæmolytic system.

Fourteen of 22 sera tested (Table 1) fixed complement with autologous brain. Eleven of these 14 sera also fixed complement with homologous brain. None of the remaining 8 of the 22 sera tested fixed appreciable amounts of complement with either autologous or homologous brain. Past work in our laboratory indicated that such complement-fixing antibodies are not present in sera of normal rats or in sera of rats injected with guinea pig kidney-adjuvant[12]. Those sera tested against homologous kidney were negative.

Table 1. Complement-fixing (CF) Antibodies in Sera of Rats after Injection of Guinea Pig Spinal Cord in Freund's Adjuvant

Rat No.	CF antibody titre of sera against indicated antigen*		
	Autologous brain	Homologous brain	Homologous kidney
*D*321	8†	8	< 4

*D*325	32	32	< 4
*D*331	4	4	< 4
*D*333	16	8	< 4
*D*334	16	< 4	ND‡
*D*335	8	8	< 4
*D*385	8	4	ND
*D*387	4	< 4	ND
*D*388	8	4	ND
*D*390	8	4	ND
*D*392	8	4	ND
*D*394	8	4	ND
*D*396	4	< 4	ND

* Sera tested in dilutions of 1-4 to 1-128 against 1 : 25 dilution of brain and kidney antigens.

† Reciprocal of greatest dilution of serum giving maximum fixation of complement.

‡ ND, not done.

As expected from previous work[4-6,12], no direct correlation existed between the occurrence of allergic encephalomyelitis and the presence of the complement-fixing antibodies detected here against either autologous or homologous brain in individual rats. Ten of 14 rats, the sera of which reacted with autologous brain, had clinical signs and/or lesions of allergic encephalomyelitis. Five of 8 rats, the sera of which did not react with autologous brain, developed disease.

Our results (Table 1) indicate that injection of rats with heterologous spinal cord may induce complement-fixing antibodies which react *in vitro* with autologous nervous tissue.

Tyrosyluria in Human Subjects

Tyrosyluria, that is, an abnormal excretion of aromatic metabolites of tyrosine, has long been known to occur in human subjects in ascorbic acid deficiency, particularly after a high tyrosine diet; it is readily abolished by feeding ascorbic acid. Recently, however, Bloxam *et al.*[1] have reported fairly rare cases of a tyrosyluria in apparently normal infants which did not seem to result from ascorbic acid-deficiency and which disappeared spontaneously with time.

We find this observation particularly interesting, since we believe that other cases of tyrosyluria, detectable by chromatographic methods though probably mostly within the normal range of less-specific analyses, occur frequently in ill subjects. We have previously described an increased excretion of some tyrosine derivatives in stress[2], and have now often observed similar phenomena in pathological urines of many types, from subjects not obviously suffering from lack of dietary ascorbic acid or from liver damage.

In many of these subjects, as with those of other workers, the characteristic compounds excreted in abnormal quantity are *p*-hydroxyphenyl-pyruvic and -lactic acids. Both substances are probably invariable minor constituents of normal human urine: the pyruvic acid has always been detected (as *p*-hydroxybenzalhydantoin) in extracts of acid-hydrolysed urine[3] and is presumably accompanied by trace amounts of the lactic acid, its reduction product. However, using extracts of urine equivalent to 1-min. excretion prepared by the method of Hill *et al.*[4] and chromatographed in *iso*propanol–ammonia followed by *n*-butanol–pyridine–water (70 : 10 : 20), we have but rarely detected (diazotized sulphanilic acid) *p*-hydroxyphenyllactic acid in healthy male British subjects, mostly young Royal Air Force personnel. It may be noted, however, that Armstrong *et al.*[5] reported it as being one of the more common constituents in their normal urines. Though this difference from our observations may well be accountable in terms of technique, diet and a less-restricted age-group of subjects, at least one other factor is of interest—the altitude (5,000 ft.) of the Salt Lake City laboratories of Armstrong and his group. Tyrosine metabolism is so linked with that of ascorbic acid that possible changes in the latter as a result of anoxia[6] leaves some ground for speculation.

Bloxam *et al.*[1] noted that the urines they examined contained *p*-hydroxyphenylacetic acid, while Boscott and Cooke[7] examined a group of subjects who rarely excreted *p*-hydroxyphenyllactic acid, but in whom the major tyrosine metabolite appeared to be *p*-hydroxyphenylacetic acid. The technique employed by the latter workers is open to some criticism, while the former did not comment on the excretion of the acetic acid by infants in general and made no claims regarding its significance. Further difficulties in interpreting this latter arise, since the acetic acid might originate from tyrosine via tyramine or via *p*-hydroxyphenylpyruvic acid, either metabolically or by decomposition in urine. At least in rats, recent work[8] has shown that it does not appear to be dependent on intestinal micro-organisms. We find *p*-hydroxyphenylacetic acid to be invariably detectable in normal urine (cf. ref. 5). Occasionally it has been detected in usually large quantity, but, with the exception of one subject who excreted it consistently thus, such occasions appear to be atypical of the subjects. In contrast, high rates of excretion have often been noted in both stress and other pathological conditions, not necessarily in subjects also excreting *p*-hydroxyphenyllactic acid. It seems necessary to consider the possibility that two distinct types of tyrosyluria do in fact exist.

Yet other tyrosine derivatives are sometimes present in large quantity in pathological urines: *p*-hydroxyphenylpropionic acid has only occasionally been noted; *p*-hydroxybenzoic acid is unfortunately certainly only derived in part from tyrosine; tyramine may be intimately connected with *p*-hydroxyphenylacetic acid; the compound recently identified with *p*-sympatol[9] may, by reason of its known physiological activity and unusual structure, be more than a mere by-product of tyrosine degradation. Another type of hydroxyphenyluria is characterized by the excretion of a group of unidentified phenols, sometimes in such relatively large amounts that it is difficult to account for them except in terms of tyrosine metabolism (the possibility of an origin from drugs has been excluded). Failure to react with 2 : 6-dichloroquinonechloroimide indicates the presence of the appropriate *p*-hydroxy grouping, while ease of oxidation suggests a possible second oxygen substituent (perhaps a conjugated hydroxyl group) in the benzene nucleus. It is of interest that Bloxam *et al.*[1] detected an unknown phenol, while Boscott and Cooke[7] more specifically stated that their subjects excreted large quantities of polyphenols, including catechol. Further, in the single classical case of 'tyrosinosis'[10] the subject excreted, besides *p*-hydroxyphenyl-lactic and -pyruvic acids, a third compound identified as 3 : 4-dihydroxyphenylalanine, though unfortunately only on the basis of its properties and a carbon–hydrogen analysis. Normally degradation of tyrosine proceeds through a 2 : 5-dihydroxyphenol, homogentisic acid.

The term tyrosyluria may cover a number of abnormalities: how each may best be characterized is at present problematical. It seems likely that the development of accurate quantitative analyses for many urinary phenols will be essential for further progress.

RADIOBIOLOGY

Strontium-90 in Human Plasma

THE average daily dietary intake of strontium-90 in Britain during 1958 has been assessed as about 6 μμc. per gm. calcium[1]. It is well known that discrimination against strontium relative to calcium takes place in absorption from the gut and excretion by the kidney[2]. The combined effect of these discriminatory processes would lead to an expected concentration of strontium-90 relative to calcium in human plasma of about one-quarter that in the diet, that is, about 1·5 μμc. strontium per gm. calcium in 1958. No measurements of the strontium-90 content of human plasma have yet been reported. On the basis of the above estimation, at least 20 litres would be required for a measurable activity to be obtained. Thus the same individual must be bled on a large number of occasions over a long period of time or many individuals must be bled to provide a bulked specimen.

The Blood Products Laboratory, Lister Institute, provided us with 70 bottles containing about 120 litres of pooled plasma unfit for transfusion because of bacterial contamination. This had been prepared from whole blood collected between November 1958 and March 1959, except for about 2 litres dating from mid-1958. The consignment was divided into two parts: (1) South London, Birmingham, Bristol, Cambridge, Cardiff, Leeds and Belfast; (2) Liverpool, Manchester, Newcastle, Sheffield and the north-east Metropolitan area. The strontium-90 content per gm. calcium in these two bulked plasmas has been determined. The results are taken to be representative of an adult population at the end of 1958.

Strontium together with calcium was precipitated in each bottle of plasma by the addition of a known excess of saturated oxalic acid. The solids were separated by centrifuging, bulked and thermally ashed at about 400° C.

The calcium content of each of the two batches was determined on a weighed aliquot by the standard oxalate – permanganate method. Strontium was separated from the large excess of calcium in the resulting ash by successive precipitations of strontium nitrate in 78–80 per cent nitric acid. The strontium-90 content was determined by separating chemically the daughter product, yttrium-90, after radioactive equilibrium had been re-established. The radioactive decay of yttrium-90 (half-life, 64 hr.) was followed over about eight days using an anti-coincidence counter. After correction for chemical loss (about 40 per cent) and self-absorption (5–10 per cent) the final results obtained were 1·1 and 1·4 μμc. strontium-90 per gm. calcium in the two batches. The estimated error in each observation was 25 per cent, so that no significance is attached to the difference between the two results. The observed concentrations of strontium-90 in plasma are thus consistent with a daily dietary intake of 6 μμc. per gm. calcium

Strontium-90 and Cæsium-137 in Grass and Milk in Finland during 1959

MILK and milk products are the main source of calcium (85 per cent of the total) in the average Finnish diet. As they are also important links in the transfer of radionuclides from atmospheric fall-out to the human body, we have started an investigation to determine the contents of some important radionuclides in Finnish milk. Results of determinations of strontium-90 and cæsium-137 for the year 1959 are reported here.

Two sets of samples were collected. 'Local' samples (Nos. 1–9, Table 1) were taken during the period August 29–September 6, 1959, on nine experimental farms between latitudes 60–69° N. and longitudes 23–27° E., where soil conditions, fertilizer practices and other agricultural factors are known in detail. 'General' samples (Nos. 10–15), analysed for strontium-90 only, were taken between May 1 and November 17, 1959, from one-day's milk intake (60–80,000 litres) of two milk-powder factories of the Kuivamaito Oy, located in south-east (*A*) and south-west (*B*) Finland. Both factories collect milk from more than ten dairies within a radius of 100 km. between latitudes 60° and 62° N.

Representative samples of grass were also collected from the experimental farms for analysis and determination of the discrimination factors for grass and milk of strontium-90 and cæsium-137.

* The error due to counting (two standard deviations) is < 14 per cent.
† Standard deviation less than 20 per cent.

Radiostrontium was isolated by the method of Bryant *et al.*[1] and β-activity was determined with a low-background counter *CE*-14 manufactured by Tracerlab.

Cæsium-137 was determined γ-spectrometrically in milk and grass ash prepared below 450° C. in the manner described, for example, by Löw and Edvarson[2] and by Lillegraven[3]. The shielding system and pulse height analyser used in this work have been described by Vuorinen[4]. The cæsium-137 activity of the milk-ash samples was calculated after correction for background and potassium counts.

Determination of cæsium-137 in the grass-ash samples was only possible after an estimation of the relative amount of zirconium-95 + niobium-95 in the spectrum (Fig. 1) by using the channels outside the maximum of the cæsium photopeak (region I in Fig. 1). A correction for zirconium-95 + niobium-95 pulses in the cæsium-137 channels, in addition to the background and potassium-40 pulses, thus became possible.

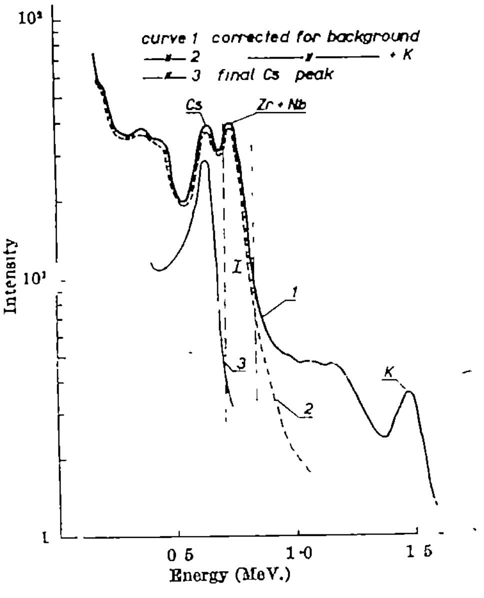

Fig 1. Differential pulse-height spectrum of the grass sample No. 9

The results are presented in Table 1. They show that the strontium-90 and cæsium-137 contents of milk in Finland do not differ essentially from that of the milk of other countries in corresponding climatic conditions[5,6]. The discrimination factor for grass and milk, that is, the ratio μμc. strontium-90/gm. calcium in milk divided by this ratio for grass, is about 0 048. The corresponding factor for cæsium-137 is 0·28.

The ratio μμc. cæsium-137/gm. potassium per μμc. strontium-90/gm. calcium for grass is 1·95 : in milk the mean for the samples from south and middle Finland (Nos. 2–8) is 5·66. The values of the two Lapland samples, however, are significantly higher, namely, the sample from Apukka (No. 1) 16·2 and that from Toivonniemi (No. 9) 19·0.

More detailed reports on this investigation will appear elsewhere.

We are greatly indebted to the Finnish Atomic Energy Commission for financial aid, to Prof. Jouko Vuorinen of the Agricultural Research Centre for advice and help, to Mr. R. Arasjärvi, and the Kuivamaito Oy for spray-drying the milk samples and to the Food and Agriculture Organization for an André Mayer Fellowship to one of us (J. K. M.).

Glutamic Acid Metabolism in Brain and Liver during Infusion with Ammonia labelled with Nitrogen-15

RECENT results of *in vivo* experiments using glutamic acid labelled with carbon-14 were consistent with the hypothesis that the amidation of the administered amino-acid to glutamine represents a metabolic event occurring in a tissue or cellular compartment[1,2]. Since glutamic acid and glutamine syntheses in the central nervous system are the two known processes by which ammonia enters organic linkage, it appeared of great interest to approach the question of setting into compartments the metabolism of glutamic acid and its derivatives with the aid of ammonia labelled with nitrogen-15.

^{15}N-ammonium acetate was infused into the carotid artery of cats over a period of 8–85 min. with simultaneous electroencephalographic and electrocardiographic tracings. The experiments were terminated by exsanguination of the animal, the blood was collected, brain and liver excised and frozen, and the level of glutamic acid and its metabolic derivatives determined in the tissue samples[3,4] as well as the concentration of nitrogen-15 in the amino or amide groups respectively of these compounds. The results of a typical experiment of 25-min duration are given in Table 1.

Table 1. ISOTOPIC CONCENTRATION IN GLUTAMIC ACID AND RELATED METABOLITES AFTER NITROGEN-15 LABELLED AMMONIA INFUSION INTO THE CAT

	Blood		Brain cortex		Liver	
	μM/gm. tissue	N-15 Atom per cent excess	μM/gm. tissue	N-15 Atom per cent excess	μM/gm. tissue	N-15 Atom per cent excess
Ammonia	2·8	81·9	1·8	65·7	4·6	42·6
Glutamine amide	0·32	21·4	7·8	38·7	0·83	28·7
Glutamine α-amino	0·32	1·8	7·8	8·6	0·83	5·4
Glutamic acid	0·08	3·1	9·8	0·87	1·6	13·6

Nitrogen-15 ammonium acetate (99·6 atom per cent excess) 1 mM/ml. infused into carotid artery of a succinylcholine paralysed 3·3 kgm. cat at a uniform rate for 24 min. (total dose, 16 m.moles). Experiment terminated at 25 min. by bleeding from the carotid artery; cortex and liver frozen *in situ* with solid carbon dioxide.

While the concentrations of the amino-acids measured in the various tissues remained constant or decreased slightly, the level of glutamine in the brain increased by at least 50 per cent (for normal values see ref. 4). The observation that the nitrogen-15 content of the amide group of cerebral glutamine is higher than that of liver or blood indicates that this amide is synthesized in the brain. Since the level of glutamine in brain increased considerably, the high specific activity of the amide group is probably not due to an exchange with free ammonia but to a net synthesis of glutamine. Circumstantial evidence for glutamine synthesis in the brain has come from experiments on hepatectomized animals[5] and is consistent with the high synthetase activity in this organ[6,7].

Of particular interest is a comparison of the concentration of nitrogen-15 in the α-amino group of glutamic acid and of glutamine isolated from the brain. Since the α-amino group of glutamine has ten times the specific activity found in glutamic acid, brain glutamine must be derived from a compartment of glutamic acid which is not in equilibrium with the total tissue content of this acid unless glutamine is synthesized appreciably by a pathway which does not require glutamic acid as the immediate precursor.

In contrast to the observations on brain, the α-amino group of liver glutamine is of lower specific activity than that of liver glutamic acid, a result which might be expected if the glutamic acid used for glutamine synthesis in the liver mixes rapidly with the total tissue pool of this amino-acid. However, in preliminary double-labelling experiments (^{14}C glutamic acid and $^{15}NH_3$) compartmentalization of glutamic acid used for glutamine synthesis can also be demonstrated in this organ in the presence of high ammonia concentrations.

If glutamic acid is utilized for the synthesis of the additional glutamine in the brain, the former amino-acid is apparently made in this organ and not derived from the blood, since the nitrogen-15 content of the α-amino group of brain glutamine (8·6 per cent) is higher than that of blood glutamic acid (3·1 per cent).

According to present evidence the reductive amination of keto-glutaric acid occurs in the mitochondria[8] while glutamine synthetase is localized in microsomes and mitochondria[9]. Further experiments will have to show whether the results of this and previous work together with evidence for the enzyme distribution in the cell are indicative of different metabolic pools within the cells for the metabolism of administered glutamic acid and of that synthesized in the tissue. This type of investigation may point the way by which the problem of setting into compartments of metabolic events *in vivo* may be approached[10]. A detailed account of the experiments as well as of the effects of ammonia infusion will be given elsewhere.

This work was supported in part by grants (*B*-557 and *B*-1312 *C*-3) of the U.S. Public Health Service.

Alpha-Activity of Wheat and Flour

IN their work on naturally occurring radioactivity in man and his environment, Mayneord and his co-workers have indicated[1,2] the wide range of alpha-radioactivity found in the more common foodstuffs. Using the same experimental method, we have recently made measurements on a number of samples of wheat and wheat products of known origin, and wish in this communication to report briefly on three aspects of our findings.

Using wheat from the United Kingdom, Canada, New Zealand, Victoria, South Australia and Western Australia, we have noticed that, while there are typical differences between wheats from these sources, with wheat from any one source there appears to be a connexion between alpha-activity and soil *p*H. As an example, we are indebted to the National Institute of Agricultural Botany for a series of samples of wheat varieties grown together, in trial, at nine different centres. A relatively small range in activity occurs between varieties, but as between locations we found these limiting cases: variety Cappelle Desprez grown on chalk soil at Sparsholt in Hampshire had an activity of 0·21 μμc./gm. ash, soil *p*H 7·8; the same variety grown on an acid loam at Winnarleigh in Lancashire had an activity of 1·66 μμc./gm. ash, soil *p*H 5·2. This ratio of 8 : 1 contrasts with that of only 2·5 : 1 for variety; the highest activity found at Sparsholt occurred in the variety Dominator, which was measured as 0·49 μμc./gm. ash. This effect of soil *p*H was also found in all foreign wheats when variety samples were compared.

With milled wheat we have compared the activities of bran and white flour with the wheat from which they were derived. The mean of six samples in each case was: wheat, 1·1 μμc./gm. ash; bran, 1·0 μμc./gm. ash; flour, 1·0 μμc./gm. ash.

It would thus appear that the alpha-activity of wheat is of soil origin, in contrast to the occurrence of strontium-90, in which the much higher content in bran as compared with flour has been interpreted[2] as due to retention of air- or rain-borne material in the developing ear of the plant.

In wheat from widely separated sources we have observed a considerable range in alpha-activity:

Source of wheat	Samples tested	Mean activity (μμc./gm. ash)
United Kingdom	30	1·0
Canada	15	1·0
New Zealand	30	2·5
Victoria	15	2·5
South Australia	2	2·6
Western Australia (Fremantle)	3	25·0

In respect of the high figures for Western Australian wheat, consistently high activities were obtained from three different shipments of this grain. The ratios of activity from thorium and radium families were similar in all cases, averaging 30 per cent.

Finally, we would mention that these results might be better expressed in terms of the calcium with which they are associated. Wheat ash (1·4–1·8 per cent of the dry weight) contains about 2·8 per cent of calcium, whereas in white flour the ash (0·5 per cent dry weight) contains nearly 4 per cent. Present legislation, however, makes it compulsory in the United Kingdom to add, as creta praeparata, 0·125 per cent of calcium to flour (except to wholemeal), thus increasing its content of calcium to 0·145 per cent.

BIOLOGY

Use of Gibberellin to hasten Germination of *Solanum* Seed

True seed of the potato (*Solanum tuberosum* L.) frequently has a delayed germination[1], and we find that this also applies to most other tuber-bearing *Solanum* species, where it is usual for seed to remain dormant from 1–3 months or longer. Geneticists and potato breeders have been inconvenienced by this difficulty. Our results with certain techniques[2,3] for hastening germination of *Solanum* seed have been variable. Since gibberellin has been used to promote germination and terminate dormancy of seeds in other genera[4–6], its effectiveness to hasten germination of *Solanum* seed was investigated by us.

In preliminary tests, gibberellin concentrations of up to 100 p.p.m. had little effect on breaking dormancy of recently harvested *Solanum* seed, but germination was stimulated by concentrations of 1,000–4,000 p.p.m. To confirm this result, dry seeds of several *Solanum* species and species hybrids were examined microscopically with transmitted light to select those containing mature embryos. Lots of 50 seed were soaked for 24 hr. in different concentrations of the potassium salt of gibberellic acid (75 per cent actual). The seeds were then washed in three successive changes of distilled water and placed on moist blotting paper in Petri dishes kept at room temperature (20–30° C.). As controls, similar lots of seed were treated with distilled water but otherwise handled in the same manner. The results (Table 1) show per cent germination for gibberellin-treated seed.

Although prolonged exposure of the seeds to the 1,000 p.p.m. concentration increased per cent germination appreciably, treatment with 2,000 p.p.m. for

[2] Agricultural Research Council Reports *A.R.C.R.L.* 1 and 3 (H.M. Stationery Office, London, 1959 and 1960).

24 hr. gave optimum germination. The 4,000 p.p.m. concentration was no more effective than the 2,000 p.p.m. concentration. At the optimum concentration the majority of treated seeds had germinated in 15 days. The gibberellin treatment accelerated germination in seeds which had little dormancy and in seeds approaching the end of their dormancy period. Seeds of *S. demissum* Lindl., U.S.D.A., *P.I.* 160227 and of a *S. chacoense* Bitt. × *S. phureja* Juz. et Buk. derivative exhibited no dormancy. Similarly, Odland[7] reported immediate germination in a number of seed lots of *S. tuberosum*.

Plants were grown to maturity from the gibberellin-treated seeds, and in all cases growth was normal. The above method has been used in our work with *Solanum* species and allows us to grow many more plant generations in a given period of time.

Pollen Germination in Some Gramineae

I. K. Vasil, in his communication under this title in *Nature* of September 24, p. 1135, states that "this is the first report of a successful germination of the pollen of Gramineae *in vitro*". May I point out that the germination of pollen of different varieties of *Saccharum officinarum* was carried out as a routine practice by the Sugarcane Research Station in Mauritius as far back as 1930. The methods used are described by Glendon Hill[1] and de Sornay[2]. Germination tests were discontinued later, as it was found that there was poor correlation between germination of pollen *in vitro* and number of sugar cane seedlings afterwards produced[3].

A Selective Medium for the Formation of Ascospores by *Aspergillus nidulans*

Little is known about the ascospore composition of the Ascomycetes, partly because of the difficulty of obtaining a massive production of such cells. During an investigation of the nutritional requirements of a strain of *Aspergillus nidulans* obtained from the Botany School Collection, Cambridge, observations were made that led to the recent development in this laboratory of a method for obtaining satisfactory yields of ascospores without interference from the conidiospores. This fact has enabled fractionation studies on *A. nidulans* ascospores to be undertaken, as well as other biochemica investigations which are now in progress.

Microscopically and culturally the strain used in these studies is similar to that described by Thom and Raper[1]. This organism, when cultured in Czapek's agar, produced colonies characterized by a dense vegetative mycelium spreading quickly on the agar, with abundant green conidial heads freely distributed on the surface of the colony, and relatively few perithecia scattered through the different area of the colony; ascospore production lasted severa weeks.

When the mould was cultured on a medium with the following composition: Urea or ammonium oxalate, 3 gm.; dipotassium hydrogen phosphate 1 gm.; crystalline magnesium sulphate, 0·5 gm. potassium chloride, 0·5 gm.; ferric sulphate, 0·05 gm.; sucrose, 30 gm.; agar-agar, 15 gm., and distilled water, 1,000 ml., colonies were formed with very different general morphology from those obtained on Czapek's medium. Under these conditions perithecia developed separately within or on the conidial layer with a dark reddish purple coloured envelope of scattered hyphæ bearing a considerable number of Hulle cells. On ripening, these became a mass of eight-spored asci which broke down quickly, releasing the ascospores. When a preparation of this material was examined under the microscope an enormous number of purple-red lenticular ascospores, with two equatorial crests, were observed, with very few contaminating conidiospores.

Another characteristic was particularly marked when plates were viewed in reverse, namely, an intense purple pigmentation extended through all the medium marking the under-surface of perithecia and ascospores. This pigmentation was absent after growth on plain Czapek's agar.

We are indebted to Mr. J. Bean of the Botany School, University of Cambridge, for sending us a culture of this mould.

Degeneration of Flight-musculature in the Corixidae and Notonectidae

Within the New Zealand species of the families Corixidae and Notonectidae (Hemiptera-Heteroptera), two distinct forms, depending on the development of the wings and the wing-musculature, have been recognized. In these species a proportion of the population is composed of flightless animals in which, apart from *Diaprepocoris zealandiae*, the indirect flight-musculature is reduced even though the two sets of wings are not significantly altered from the normal condition. In *D. zealandiae* the meta-wings are greatly reduced and the meso-wings differ in having a reduced membranous portion.

The differences in the musculature are obvious immediately the mesothoracic tergite is removed, for in place of the solid blocks of yellow fibre the flightless form contains either a pale white, loosely compacted ibrous mass, or, more usually, only parenchymatous tissue. There are a number of differences, too, in the form of the body and the extent of chitinization and pigmentation. Without recourse to dissection, the two forms may be readily distinguished. Flightless animals, besides being significantly smaller, are less pigmented, and the chitinization, particularly of the thorax, is greatly reduced.

Although the degree to which the flightless animal is modified from the normal condition varies throughout these species, within each of them the extent of the modification is remarkably uniform and no intermediate forms have been discovered. This uniformity applies not only to the condition of the musculature but also to the modifications already noted. This situation follows from the mechanism by which the condition is developed. Normal growth of the wing-musculature is not continued throughout the fifth instar, and at the conclusion of the moult to the imago the final modifications of the skeleton have been achieved, although the histolysis of the partly developed fibres and their replacement by parenchyma continues for a short period.

The factors responsible for the control of the development of the muscle-form reside in the environment, and until late fourth instar either form may be produced depending on the habitat conditions. A close association between the environmental conditions, with respect to stability of the habitat during drought, and the muscle-form developed in the population, results from delaying the critical period for this control until the fifth instar. Almost without exception, the less-stable habitats within the species range contain only animals with normal musculature. In stable areas—streams and lakes in which the population may be maintained throughout the year—both forms are found, but the population is predominantly of flightless individuals. Flying animals are necessary for the maintenance of populations in the unstable habitats of the species range; through migration they re-establish the species in habitats that have been dry during the summer.

From a comparison of the extent of the changes that are associated with the cessation of wing-muscle growth in the species of *Sigara* and in *D. zealandiae*, it is apparent that the loss of this musculature is an early stage in the process leading to the brachypterous condition: the wing-musculature is first reduced and only then are the meta-wings modified.

In the New Zealand fauna this condition of the musculature which gives rise to flightless animals without alteration of either pair of wings has been recognized in each of the seven species of *Sigara* (*Tropocorixa*) and in the two species of *Anisops*. With experience of the modifications resulting from the change in musculature, it is apparent from the accounts of these two families in other localities that this condition occurs in a number of other species. The two colour forms described by Brooks[1] in *Anisops* are due to this feature. *A. wakefieldi*, a species found in New Zealand, is considered in this work and the two forms dependent on the condition of the musculature are described, although no explanation is offered to account for them. The numerous brachypterous forms recorded in the species considered by Hungerford[2] and Poisson[3] suggest that many other species in which the musculature only is reduced probably occur also. Finally, Brown[4] attributes the anomalies noticed between the abundance and migration-rate in a series of British Corixidae to physiological factors. It seems more likely that, as the species in which the relation was least satisfactory were associated with stable habitats, this was a consequence of the reduction of the flight musculature in these animals.

A fuller account of this work is being published elsewhere.

Environment and Reproduction in Freshwater Triclads

Reproduction in triclads varies from asexual to complicated sexual methods[1,2] both within and between species. Attempts to determine the causes of such differences resulted in controversy between students favouring the external environment[3] and those favouring an internal physiological process[4,5] as the determinant.

Dahm's[2] researches on triclads inhabiting running water, coupled with work[6,7] on the triclads of standing water, suggest a broad relationship between habitat and mode of reproduction. When triclad species are arranged in a series based on increasing productivity of the habitat (*sensu* Ruttner[8]), often accompanied by higher average temperatures, it extends from *Phagocata vitta*, which is found in the harshest conditions inhabiting moorland streams and upland lakes, to *Dugesia lugubris*, which is found only in the most productive lakes and quieter reaches of some lowland rivers. Table 1 shows such a series for the commoner freshwater triclads of northern Europe

Table 1. North European Species arranged in Order of Productivity of their Habitats, showing Prevalent Types of Reproduction

	Species	Habitat		Reproduction			Cocoons
		Lotic	Lentic	Asexual only	Both	Sexual only	
Increasing productivity ↓	*Phagocata vitta* (Dugès)	X		+++	+	+	Winter
	Crenobia alpina (Dana)	X		+++	++	+	Winter
	Polycelis felina (Dalyell)	X		+++	+	+	Winter
	Dugesia gonocephala (Dugès)	X		+	+	+++	—
	P. nigra (Mull.)	X	X		+	+++	Early spring
	P. hepta (E. H. and Y. Melander)		X			+++	Spring
	P. tenuis (Ijima)		X			+++	Spring
	Dugesia lugubris (Schmidt)		X			+++	Early summer
	Dendrocoelum lacteum (Mull.)		X			+++	?

together with the mode of reproduction and the season of sexual reproduction.

Asexual reproduction is the usual means of population increase in species occupying unproductive habitats, and it becomes progressively less important and is finally replaced altogether by the sexual process in species found in the most productive habitats. This is also accompanied by a change in the season at which the sexual process occurs. Thus, in *Phagocata vitta* and *Crenobia alpina*, and to a lesser degree in *Polycelis felina*, sexual reproduction occurs mainly in winter in North European populations. *Polycelis nigra* starts to breed in the early spring[9], *P. tenuis* and *P. hepta* slightly later, while *D. lugubris* does not begin until the late spring or early summer[10].

Dahm showed that growth and reproduction of species living in unproductive streams are possible only when the basic metabolism is slowed down by low temperatures characteristic of winter conditions; this applied over a range of feeding regimes. In species such as *P. tenuis* which live in lakes of intermediate productivity I have found that, while winter temperatures inhibit breeding, it occurs at temperatures characteristic of the British spring and summer. Breeding in *D. lugubris* is rather more sensitive to low temperatures and rather less to high temperatures. In both species breeding ceases when they are kept at temperatures higher than those of an average summer (about 24° C.), and this is followed by retrogression of the reproductive organs and a decline in size despite a plentiful supply of food. Such a relationship between energy intake and expenditure might explain the infrequency of sexual reproduction in species occupying unproductive habitats and its restriction to colder periods. Under such conditions food would never be plentiful, but would be particularly scarce when low temperature would favour the channelling of energy into growth and ultimately reproduction. Sexual reproduction therefore might be so restricted that without other means of multiplication many populations would become extinct. The existence of asexual methods of reproduction in such species as *Ph. vitta*, *C. alpina* and *P. felina* solves this problem. The tendency to breed in winter suggests that high temperature is more important than scarcity of food in preventing sexual reproduction under natural conditions in northern Europe. In contrast, sexual reproduction in species living in productive habitats would be possible each year when abundance of food (relative to activity), permitted growth and reproduction in a proportion of the population. In these circumstances sexual reproduction, which is regarded as conferring advantages from an evolutionary point of view, would be more common.

Clearly, apart from the basic differences in the ability of the several species to function at various temperatures, any differential effect of temperature might emphasize the contrasts outlined above between the triclads of unproductive and productive habitats. From the available data[11,12] such a differential appears to be present, and species like *C. alpina* and *P. felina* not only have a higher basic level of activity but also are unable to control their activity when the temperature is increased as, for example, *Dugesia gonocephala* can.

It is interesting to note that Dahm also found that within a single species there were populations which could only reproduce asexually (usually polyploids with odd multiples of the haploid chromosome number), some which could multiply both sexually and asexually, and others which showed only sexual reproduction. It would be rewarding to study the ecology of such populations to determine the relationship between the habitat and mode of reproduction.

If it is assumed that the primitive triclad reproduced by both methods, then it appears that selection has operated to suppress sexual reproduction in the species of unproductive habitats and asexual reproduction in those of productive habitats.

A Possible Method of Sex Ratio Determination in the Parasitic Hymenopteran *Nasonia vitripennis*

Nasonia vitripennis (Walter) (Pteromalidae) is parasitic on the pupal stage of muscoid flies. The female drills through the host puparium and lays eggs on the pupa within. When a population of *N. vitripennis* has ready access to host puparia, each generation of the offspring is composed of females and males in the ratio 3 : 1[1]. The females are diploid and the males haploid[2]. So far, no suggestion has been made as to how this sex ratio may be determined; but it seems possible that it may be affected by the arrangement of the eggs in the ovariole before fertilization. The eggs are shaped like curved sausages and are more pointed at one end than the other. This is the typical hymenopterous shape. Owing to its curvature, each egg has in its meridional plane a convex and concave side. Within each ovariole the eggs are orientated so that the oldest eggs, namely those nearest the oviduct end of each of the four ovarioles which comprise a single ovary, almost always have their convex aspect pointing away from the axis of the ovary as a whole (Fig. 1). This arrangement was observed in 46 out of 50 insects examined.

The chorion of the egg is rigid compared with the very thin walls of the vagina and oviduct, and it is a reasonable assumption that the eggs either maintain their orientation or twist in a more or less constant manner as they leave the ovariole and pass one at a time through the short oviduct into the vagina. If either of these suppositions were true, the eggs from adjacent ovarioles would lie in the vagina successively so that their concave aspects make an angle of 90° to each other. All the eggs from any one ovariole should generally be orientated the same way when they arrive in the vagina.

In the vagina, the eggs come into contact with a muscular tongue which projects into the vagina from

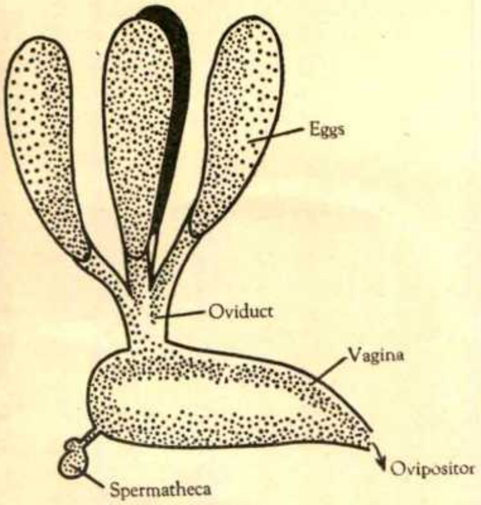

Fig. 1

its dorsal surface (Fig. 2). Flanders[3] described a similar tongue in *Nemeritis canescens* (Grav.) and suggested that it might press the micropyle of the egg against the spermathecal duct, which opens on the postero-ventral surface of the vagina in the mid-line. In this way the chances of fertilization would be improved. It seems possible that the vaginal tongue of *Nasonia vitripennis* functions in a similar way. From Fig. 2 (*b*, *c*) it can be seen that, when an egg's concave face is either dorsally or laterally orientated in the vagina, the tongue could press the egg's micropyle against the opening of the spermathecal duct; when the meridian of the egg is ventral as in Fig. 2 (*a*), however, the tongue would force the micropyle away from the duct of the spermatheca so that the sperm could not enter the egg. Therefore, on average one-quarter of the eggs laid would not be fertilized and so produce males. This suggests that all the eggs from one of the ovarioles may not be fertilized, and it accounts for the observed sex ratio of 21 per cent males in populations which had free access to host puparia[1].

When mated females are deprived of host pupæ for four days prior to oviposition, the proportion of males in the offspring increases to 38·9 per cent[1]. It is known that if eggs are not laid within two days of their reaching maturity a process of resorption begins. Until now it has been suggested that in many Hymenoptera a partially resorbed egg produces a female because it is in the ovary longer and so stands a better chance of being fertilized[4]. On the present hypothesis, an alternative explanation would be that the tongue cannot push the partially resorbed egg's micropyle against the spermathecal duct because the egg has lost its shape and rigidity, Fig. 2 (*d*). The egg is therefore not fertilized and produces a haploid male.

Occurrence of an Egg-String in *Enoplus communis* Bastian, 1865 (Nematoda : Enoplidae)

Adult members of the phylum Nematomorpha, residing in aquatic habitats, lay their eggs within long strings commonly referred to as 'egg-strings'. In the nematomorphs this egg-string is considered a secretory product of the antrum (a common chamber situated between the uteri and the cloaca and lined with a layer of glandular epithelium)[1]. Whereas the egg-laying habits of the nematomorphs are fairly well described, those of marine nemas are practically unknown. Hyman[1], in the Nematoda section of her invertebrate compilation, states that some marine nemas lay their eggs in an adhesive mass. Recently, the opportunity to elaborate on this observation was presented while I was studying marine nemas at the Woods Hole Oceanographic Institution, Woods Hole, Massachusetts.

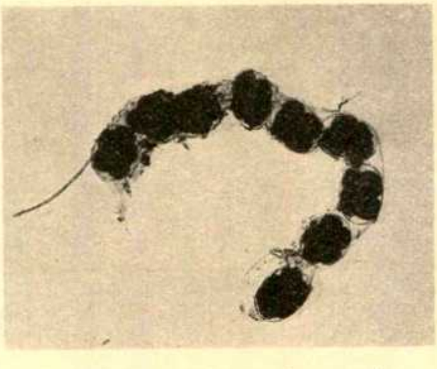

Fig. 1. 'Egg-string' of *Enoplus communis*

Live specimens of *Enoplus communis* Bastian, 1865, taken from the holdfasts of unidentified marine algae collected from Penzance Point at Woods Hole, were placed in a watch-glass in sea-water and left for 10–12 hr. Low-power examination of the specimens then revealed the presence of a line of 22 eggs. Higher magnification showed that each of the 22 eggs was contained within a continuous, transparent sheath (Fig. 1). In this respect the egg-containing sheath (egg-string) of *E. communis* appears to be analogous to that of the Nematomorpha. This sheath was attached to the bottom of the watch-glass, was adhesive, and contracted when probed with a dissecting needle. Presumably, the sheath anchors the eggs in habitats where they might otherwise be carried away or washed ashore by tidal action or else be subject to predation if deposited freely.

The sheath was at first thought to have arisen from vaginal (or vulvar) glands. However, on examination of *E. communis* females *in toto* and in cross-section, glandular structures were not observed. Histological studies are being conducted in an attempt to determine whether glandular tissue, possibly epithelium analogous to that of the antrum of the Nematomorpha, is associated with the distal portions of the reproductive tract.

It was also noticed that, though eggs within adult females were unsegmented, those in the egg-string were segmented and at the 6- to 8-celled stage of development.

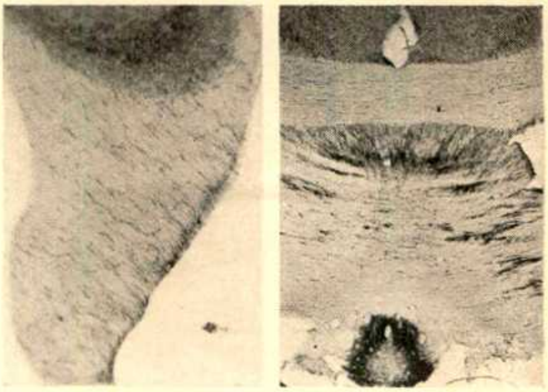
ANATOMY

Cholinergic Nervous Pathways in the Forebrain

In a previous communication[1] we described the use of a modified Koelle technique to produce selective staining of certain nuclei and tracts in the rat hindbrain. We have applied recently a similar method to the forebrain of normal animals and after transcortical lesions performed with an ophthalmic knife or cautery. The brains were removed after perfusion with 10 per cent formol saline, and 5–6 mm. transverse slices were afterwards fixed in the same fluid in the cold. To facilitate cutting, the tissue after fixation was soaked in 20 per cent alcohol, or embedded in an alginate gel according to a technique to be described elsewhere. The various media used for incubation contained either acetylthiocholine or butyrylthiocholine as substrates, with or without the addition of 10^{-4} M ethopropazine as a pseudocholinesterase inhibitor.

In sections of normal brains incubated with acetylthiocholine substrate, the forebrain tracts which stained selectively included the ventral supra-optic decussation, the central core of the fasciculus retroflexus, the cingulum, and the most lateral and most medial elements of the stria terminalis. In addition, stained fibres were interspersed in considerable numbers among the unstained fibres of the efferent projection pathways of the hippocampus: that is, in the alveus and in the dorsal fornix and fimbria behind the ventral hippocampal commissure. Caudally, most of the stained fibres of the dorsal fornix pierce the dorsal hippocampal commissure and so connect with the alveus, although some may connect with the cingulum via the corpus callosum. In the fimbria the stained fibres appear closely packed along its ventrolateral border (Fig. 1*a*). No fibres were seen in the descending columns of the fornix, and the crossed fibres of the ventral hippocampal commissure were likewise unstained. Below this commissure heavy staining due to true cholinesterase was rather unexpectedly found in the subfornical organ or intercolumnar tubercle (Fig. 1*b*), especially around its periphery, where a fine nervous plexus can be detected in sections stained by the Bodian silver method.



(*a*) (*b*)

Fig. 1. *a*, Stained fibres of fimbria. Blood vessels also present, unstained in sections incubated with pseudocholinesterase inhibitor. *b*, Stained fibres of cingulum above corpus callosum, and of dorsal fornix between corpus callosum and ventral hippocampal commissure. Stained cells belonging to nucleus of ventral hippocampal commissure. Subfornical organ heavily stained below commissure

A high concentration of true cholinesterase within the axon, such as has been demonstrated in all the tracts mentioned above, is characteristic of cholinergic neurons[2]. Having observed in the hindbrain that the cell bodies of such neurons are themselves rich in enzyme and stain heavily by the Koelle method[3], we have attempted to trace some of these presumably cholinergic pathways of the forebrain to their nuclei of origin. The lateral fibres of the stria terminalis appear to run caudally from cells of the bed nucleus of that tract to the unstained area occupied by the central amygdaloid nucleus. The medial fibres associated with the stria terminalis, on the other hand, have no connexion with either the lateral amygdaloid nucleus or the nucleus of the lateral olfactory tract, which are the two stained nuclei of the amygdala, but appear to run forward from the ventral nucleus of the lateral geniculate body, and curve downwards and backwards in front of the reticular nucleus of the thalamus. Sagittal sections show some fibres of the cingulum arising from small, deeply stained cells of the nucleus of the diagonal band; others are probably derived from similar cells of the medial septal nucleus. These two nuclei are also a likely source for the stained fibres of the dorsal fornix and fimbria, although there may be some contribution from the interstitial nucleus of the ventral hippocampal commissure. The cells of this nucleus stain intensely (Fig. 1*b*), but are larger than those of the medial septal and diagonal band nuclei, and are unusual in containing some pseudocholinesterase (found intraneuronally elsewhere in the forebrain only in the anterior nuclei of the thalamus). Our observations suggest, therefore, that the cholinergic neurons of the cingulum, dorsal fornix and fimbria belong to the afferent hippocampal system described by several workers, for example, Daitz and Powell[4] and Cragg and Hamlyn[5,6].

We have tried to confirm experimentally the polarity of the stained fibres related to the hippocampus in rats which have been subjected to lesions involving the tracts and allowed to survive four days. In these animals fibres caudal to the lesion fail to stain, whereas those immediately rostral to it dilate, stain more intensely than the equivalent fibres on the unoperated side, and become characteristically beaded[7]. We believe that this constant finding is due to enzyme accumulating on the cell body side of the axon adjacent to the cut and disappearing on the other side, as was found to occur in peripheral nerve by Sawyer[8], and indicates that the cholinergic fibres of the cingulum, dorsal fornix and fimbria are directed caudally. We hope to extend this method to investigate the polarity of other cholinergic tracts of the forebrain.

Effect of Limb Ablation on Neurones in *Xenopus* Larvæ

In the spinal cord of larval Anura, the motor cells which innervate the muscles of the hind limbs form ventral horns distinct both in position and time of appearance from the series of primary motor cells whose axons run to the trunk muscles. In the tadpole of *Xenopus laevis*, there are about 4,000 ventral horn cells at the time of their differentiation from the mantle layer of the cord, a number which has fallen to 1,200 by metamorphosis some eight weeks later[1]. 'Histogenic cell degeneration'[2] accompanies the differentiation of these neurones, but on a scale much beyond that required merely to reduce their number to the adult-level. It seems that, for every ventral horn cell that persists, some eight or nine undergo cell death during development. Differentiation of the ventral horn is thus accompanied by a continuous turnover of the constituent neuroblasts.

If the larval hind limb is amputated at the thigh, a sequence of cellular changes is initiated within both the cord and the dorsal root ganglia. From the second to the third day after amputation, the number of cell degenerations within the ventral horn on the operated side is increased, and the total number of cells thereby temporarily diminished. While the degeneration which normally accompanies differentiation of the ventral horn can be temporarily abolished by X-rays, the additional cell deaths consequent on limb amputation are unaffected by radiation.

Fresh neuroblasts from the mantle layer, however, enter the ventral horn, and the deficit in cell number is made good. This movement of cells continues beyond the level required to restore the original total, and from the fifth to the fifteenth day after amputation the number of ventral horn cells on the operated side is greater than that on the other. Finally, a second phase of cell degeneration reduces the ventral horn to a third of its normal total of cells. This final destruction of neurones affects particularly the posterior two-thirds of the ventral horn, which is thus shown to be principally concerned with the innervation of distal limb segments. The leg only rarely regenerates when the operation is performed at late larval stages.

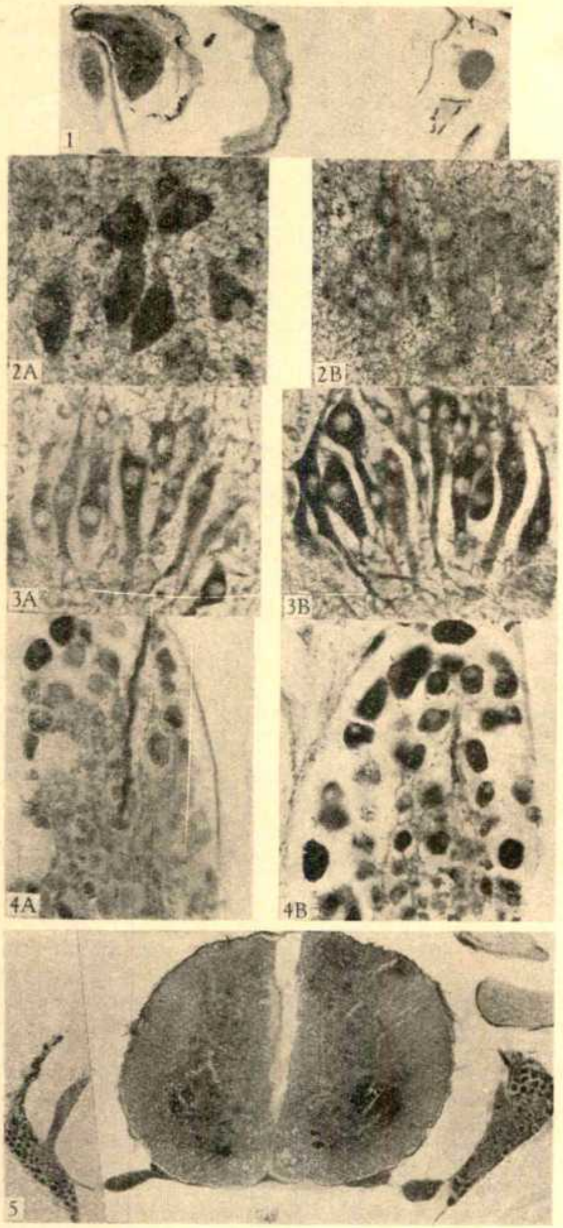
While these fluctuations in cell number are in progress, various changes are occurring in the ventral horn cells the axons of which have been severed by the operation. Attention was concentrated on changes in the Nissl substance and in the cholinesterase activity. Changes in Nissl substance were studied by ultra-violet absorption and controlled staining with basic dyes. Changes in the enzyme activity were studied by a special modification[3] of the thiocholine technique applied to small but intact specimens which were afterwards embedded in paraffin and sectioned. The sections were counterstained with buffered cresyl violet so that both Nissl substance and enzyme activity could be studied in the same neurone. In some of these preparations 10^{-4} M ethopropazine, a selective inhibitor of pseudocholinesterase, was used to confirm that only the distribution of true cholinesterase was being studied.

From the third to the fifth day, the ventral horn cells on the operated side show the typical reactions which were first described by Nissl in 1892 as 'chromatolysis', and have since been confirmed by numerous observers. The Nissl substance largely disappears, the cell cytoplasm becomes swollen, the nucleus moves towards the cell surface on one side, and the nuclear membrane becomes uneven in outline. By the eighth day, most neurones are recovering from this condition. The cytoplasm regains its normal dimensions, and, as the Nissl substance is re-formed, the chromosomal network within the nucleus becomes unusually distinct. In some of the largest cells this phase is succeeded by one in which cytoplasmic basiphilic material becomes densely piled round the nuclear membrane. This dense zone extends on opposite sides of the nucleus towards each pole of the cell. After the final phase of cell degeneration within the ventral horn, cells of this type are no longer to be found.

During the initial stages of chromatolysis the enzyme activity of the ventral horn cells on the operated side is at least as great as that on the control side and is often significantly greater (Figs. 2*A* and 2*B*). This enhanced enzyme activity is no longer present a week after ablation, and from then onwards an increasing proportion of cells on the operated side show only weak activity (Figs. 3*A* and 3*B*). Of such cells, although some are new immigrants which have not yet acquired the enzyme in any concentration, others are recovering from chromatolysis, and may show a dense perinuclear ring of basiphilic material. The weakly reacting neurones disappear from the ventral horn in the final wave of degeneration, after which the remaining cells, though of different sizes, are all strongly reacting (Fig. 5).

The most mature cells within the dorsal root ganglia of later larvæ show a weak but definite reaction for cholinesterase, the distribution of which can be studied by prolonging the incubation time in the thiocholine technique, and here, too, a sequence of changes is evident in those ganglia which supplied an ablated limb. Thus, after a week many of the cells no longer stain (Figs. 4*A* and 4*B*); during the third week many cells degenerate, leaving a ganglion which is much smaller than on the control, unoperated side but which contains about the same proportion of stained cells (Fig. 5).

Marked changes also occur peripherally. In the nerve trunk supplying a normal hind limb a proportion of the fibres stain for true cholinesterase. Following limb ablation this staining becomes much more intense, and individual fibres become noticeably distended (Fig. 1). Accumulation of enzyme in the severed axons is detectable near the cut ends within a few hours, and during the next few days it gradually increases in extent backwards towards the spinal cord at a rate of about half a millimetre per day. Later, this staining becomes less intense and eventually the fibres degenerate. Similar changes have been observed in the rat forebrain following lesions which interrupt cholinesterase-positive tracts to the hippocampus[4].



Figs. 1–5. All figures are from transverse sections prepared by the modified thiocholine technique through late larvæ of *Xenopus laevis* at various times after amputation of one hind limb. In each figure the operated side is shown on the left

Fig. 1. Through level of the sciatic nerves; 3 days after amputation. The nerve on the operated side is swollen and intensely stained

Fig. 2. Through level of the ventral horn; 4 days after amputation. The chromatolytic neurones, with displaced nuclei (*A*), are more intensely stained than the normal ones on the unoperated side (*B*)

Fig. 3. Through level of the ventral horn; 7 days after amputation. The post-chromatolytic neurones (*A*) are now less intensely stained than the normal ones (*B*)

Fig. 4. Through dorsal root ganglia supplying the hind limbs; 8 days after amputation. The proportion of strongly stained cells is much lower on the operated side (*A*) than on the normal side (*B*)

Fig. 5. Through dorsal root ganglia and cord; 18 days after amputation. There are now fewer cells in both the dorsal root ganglia and the ventral horn on the operated side

VIROLOGY

Determination of the Concentration of Myxoviruses and of Some Specific Antisera, based on Neuraminidase Activity

Of the different properties of the viruses of the myxogroup, for example, infectivity, antigenic properties, hæmagglutination and enzymic activity, only hæmagglutination has so far provided moderately rapid and accurate titration methods for the determination of myxovirus concentrations. A disadvantage of these methods is the necessary use of red blood cells, which are difficult to standardize.

We have devised a method for determination of myxovirus concentrations, based on the enzymic activity of the virus particles. The action of the virus enzyme—its ability to destroy the hæmagglutination-inhibitory capacity of some mucoproteins or to elute the virus from red blood cells—always leads to the splitting off of a sialic acid, mostly N-acetylneuraminic acid[1]. This neuraminidase activity can be measured by determining the amount of free sialic acid released by the enzyme when the virus is incubated at 37° C. with a suitable substrate. As substrates we use the mucoprotein prepared by alcohol precipitation from human urine[2], or the compound of low molecular weight N-acetylneuraminyl-lactose isolated from cow

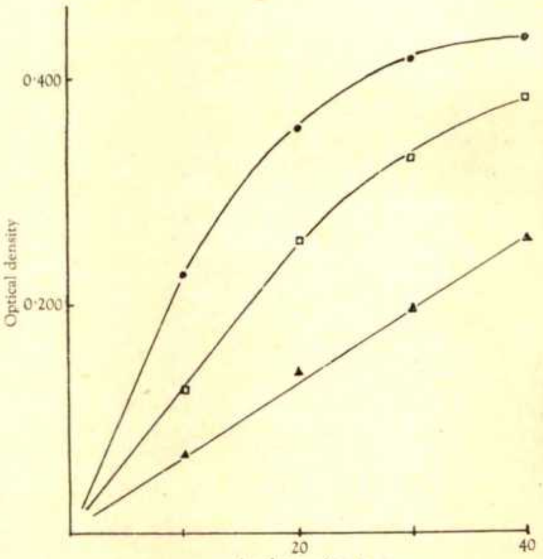

Fig. 1. Cleavage of N-acetylneuraminyl-lactose (100 μgm./ml.) by a sample of influenza virus neuraminidase (strain A_2-Singapore 1957) in several dilutions (▲, × 64; □, × 32; ●, × 16), as a function of the incubation time

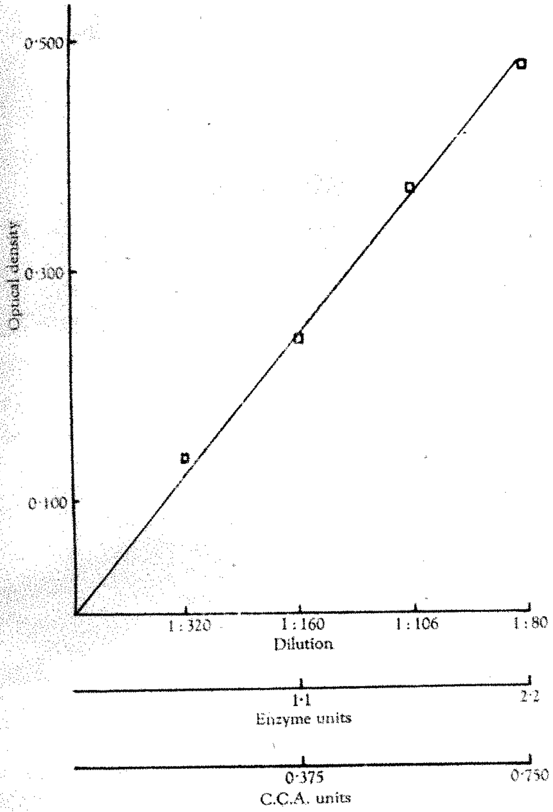

Fig. 2. Determination of neuraminidase (virus)-concentration, strain A_2-Singapore 1957 by cleavage of N-acetylneuraminyl-lactose. Relation between dilution factor and N-acetylneuraminic acid released (optical density) after incubation for 30 min. The virus dilutions on the horizontal axis are compared both with the amount of enzyme units in the sample (one unit representing the amount of enzyme that releases 1 μmole of N-acetylneuraminic acid in 1 min. under the pH and temperature conditions used) and with the amount of hæmagglutinin (chicken red cell agglutination units (ref. 6))

colostrum by a procedure rather similar to that used for N-acetyl-O-acetylneuraminyl-lactose[3]. The free N-acetylneuramic acid is estimated by the $NaIO_4$-thiobarbituric assay of Warren[4], which assay is negative for the N-acetylneuraminic acid, ketosidically linked in the substrate. We use the Warren method with some modifications such as a correction for slight cloudiness by subtracting the optical density at 600 mμ or by mixing the organic phase with 2·5 per cent v/v acetone to avoid any cloudiness. Cuvettes with a 4-cm. light path were used.

In Fig. 1 the action of a myxovirus enzyme is shown. During the incubation of the substrate (here N-acetylneuraminyl-lactose) and the enzyme—influenza virus A_2 1 (1957 Singapore)—at 37° C., samples are taken at various intervals for the determination of the N-acetylneuraminic acid release. By the addition to the samples of the strongly acid $NaIO_4$-H_3PO_4 reagent the enzyme reaction is stopped promptly. It may be seen that when the virus and substrate concentrations are rightly chosen, the amount of N-acetylneuraminic acid released is directly proportional to the incubation time. With this method it can further be shown that myxovirus neuraminidases follow Michaelis–Menten kinetics[5].

When a series of virus preparations of suitable dilution are incubated with the substrate for a standard time, the relationship between the N-acetylneuraminic acid released and the virus dilution factor is found to be linear (Fig. 2). It is thus possible to express the virus concentration in enzyme units; furthermore, the strength of an unknown virus suspension can be determined by measuring the enzymic activity of several dilutions of this suspension and comparing it with that of a standard. When the determination is performed with only one virus dilution, in the range where the effect varies linearly with the concentration, the accuracy is equal to that of the chicken red cell agglutination method[6].

We applied this method to the influenza virus strains: *A* PR_8(1934 U.S.A.), A_1FM_1(1947 U.S.A.), A_1 5(1953 Nederland), A_2 1(1957 Singapore), A_2 305(1957 Japan), *B* Lee(1940 U.S.A.), *B* Bon(1942 Australia), *B* 33(1958 Johannesburg), to *A* Swine influenza Swine 15(1930 U.S.A.) and to Newcastle disease, strain Hitchner *B*1. Determinations can only be carried out, however, with more or less purified virus suspensions, since crude allantoic fluid was found to contain inhibitory substances. The concentration of receptor-destroying enzyme in filtrates of *Vibrio cholerae* can be determined in the same way. It is interesting to note that the quotient neuraminidase units/chicken red-cell agglutination units varies strongly for the different virus types, being highest for the two *A*2 strains.

Myxovirus antibodies can be demonstrated by their inhibition of viral hæmagglutination. It seemed interesting to know if the viral enzymic activity is also blocked by antiserum. This proved to be true for the antibodies against two Asian influenza strains A_2 1(1957 Singapore) and A_2 305(1957 Japan), but not for some other strains, for example, A_1 5(1953 Nederland) and *B* Bon(1942 Australia). The concentration of the antibodies against the two Asian strains can be determined by measuring the degree of inhibition of enzymic activity (Fig. 3). In these antibody determinations we use monovalent vaccines, prepared with β-propiolactone, which retain their enzymic activity.

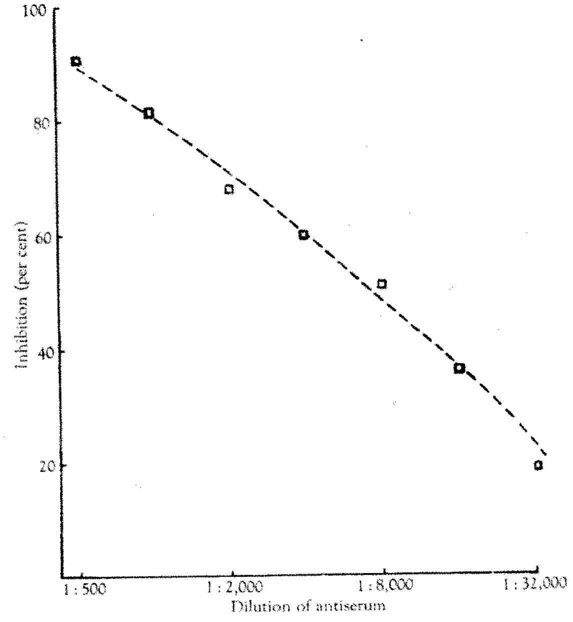

Fig. 3. Inhibition of neuraminidase activity of A_2-Singapore 1957 by homologous rabbit antiserum

This, and further work, will be reported in detail elsewhere. We acknowledge the technical assistance of Miss A. J. Schirmer.

MISCELLANY

Sampling of Sub-micron Particles for Electron Microscopy

IN recent work on the attachment of radioactive particles to Aitken nuclei, we have been concerned with the sampling and subsequent examination by electron microscopy of Aitken nuclei in the size-range $0 \cdot 01$–$0 \cdot 1\mu$ diameter. A thermal precipitator was used for sampling, and the nuclei were at first collected on an electron microscope grid covered by a carbon film, instead of on the usual glass coverslip. Doubts arose as to whether the sample was a uniform one or whether there was preferential deposition over the copper bars of the grid by reason of the increased thermal gradient in the neighbourhood of the bars or by sagging of the carbon film between them. This effect has already been reported by Cartwright[1], who, to obtain uniform samples, used the thermal precipitator with the usual coverslips coated with a 'Formvar' film. After collection of the sample the film was scratched into sections of suitable size, floated off the coverslip in distilled water and placed on a grid for subsequent examination by electron microscopy. Cartwright observed preferential deposition on the grid bars of dust particles up to a few microns in diameter by means of an optical microscope, but in the present work the Aitken nuclei were too small for optical microscopy, and nuclei deposited over the grid bars could not be seen with the electron microscope.

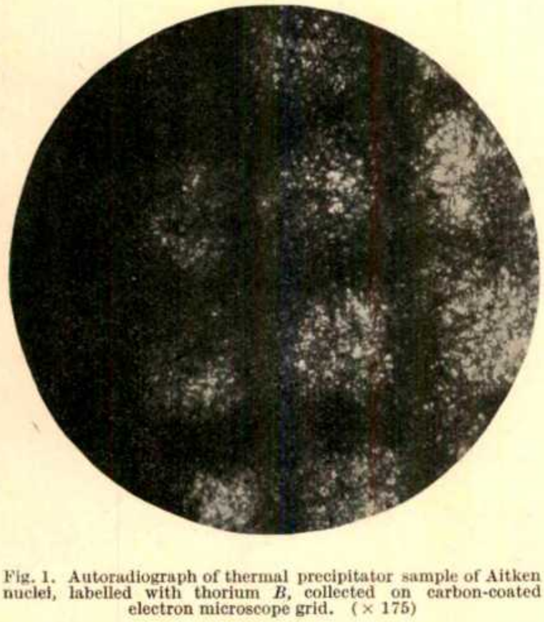

Fig. 1. Autoradiograph of thermal precipitator sample of Aitken nuclei, labelled with thorium *B*, collected on carbon-coated electron microscope grid. (× 175)

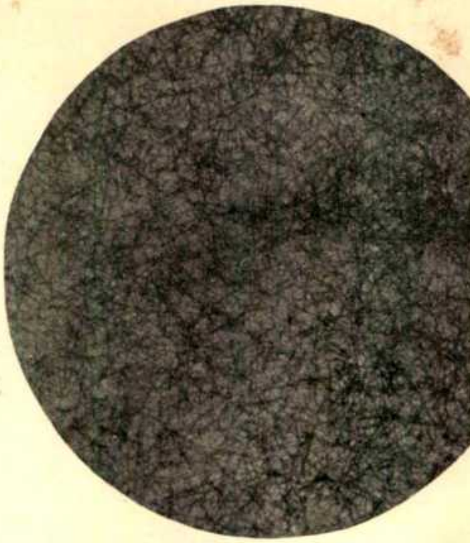

Fig. 2. Autoradiograph of simultaneous sample collected on carbon-coated coverslip. (× 175)

The technique finally used to test the uniformity of the sample was to mark the Aitken nuclei with atoms of thorium *B* and then to autoradiograph the samples. Areas where Aitken nuclei were concentrated could then be distinguished by the local concentration of alpha tracks. The autoradiographs shown are from the same thermal precipitator sample taken with an electron microscope grid (Fig. 1) and a coverslip (Fig. 2), both coated with an evaporated film of carbon, on opposite sides of the heated wire. It is apparent that the deposit on the coated coverslip is very much more uniform than that on the grid. Evaporated carbon films were used in preference to 'Formvar' because of ease of production and increased strength in the electron beam.

The method of marking the nuclei with thorium *B* was to pass filtered air at the rate of 200 cm.^{3}/min. through a solution of 5 mc. of radiothorium (thorium-228) in 40 ml. of $0 \cdot 05$ normal nitric acid. The thoron carried over was then passed into the vessel containing the nuclei to be marked. The short-lived thoron decayed in the vessel to give the thorium *B* atoms which attached themselves to the nuclei present.

Because of its low sampling-rate, the thermal precipitator is not a very convenient instrument in the present application, and we hope to develop a method of sampling on to carbon-coated coverslips by electrostatic precipitation.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, January 30

University of London (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 5 15 p.m.—Dr. P. F. R. Venables: "The Problems of Isolation in Technical Education".*

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 5.30 p.m.—Prof. J. P. Den Hartog (Massachusetts Institute of Technology) "Topics in Mechanical Vibrations. 1: Torsional Vibrations in Engine Systems caused by Gear Inaccuracies".* (Further lectures on February 1 and 2.)

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p m.—Dr. James Taylor "The Springs of Progress". (Second of three Cantor Lectures on "The Modern Chemical Industry in Great Britain")

Tuesday, January 31

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p m —Dr. W. A. Smeaton: "Science and Politics during the French Revolution".*

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 30 p.m.—Dr. H. E. M. Kay "Transplantation of Hæmopoietic Cells".* (Sixth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. L. S. Yoxall: "Instrumentation—Past, Present and Future".

Wednesday, February 1

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. F. G. J. Hayhoe: *"Cytology of Leukæmic Cells"*.*

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 p.m.—Dr D. J. Bartholomew: "A Test of Homogeneity of Means under Restrictive Alternatives".

Royal Society of Medicine, History of Medicine Section (at 1 Wimpole Street, London, W.1), at 5 15 p.m.—Mr. J. T. Rowling: "Pathological Changes in Mummies"; Dr. P. A. Zorab: "The Historical and Prehistorical Background to Ankylosing Spondylitis"; Mrs. Glemser: "The Anthropological Applications of Blood Grouping".

British Institution of Radio Engineers, Radar Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. D. E. N. Davies "A Fast Electronically Scanned Receiving System".

Institute of Information Scientists (at the Swedenborg Society Hall, 20 Bloomsbury Way, *London*, W.C.1), at 6.15 *p.m.*—Mr. F. W. Cousins: "Language at the Interface of Technology and the Law".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. J. C. Pinder: "The Economics of Agricultural Chemicals and Fertilizers".

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Meeting on "X-Ray Fluorescence". Mr. K. M. Bills: "X-Ray Fluorescence Spectroscopy"; Dr. F. Brown: "Some Analytical Applications of X-Ray Fluorescence Spectrometry".

Thursday, February 2

Institute of Physics and the Physical Society (in the Physics Department of Imperial College, Prince Consort Road, South Kensington, London, S W.7), at 2.45 p.m.—Dr. J H. Sanders: "The Optical Maser"; Dr. W. R. Hindmarsh: "Collision Broadening and Shift in Atomic Spectra".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m —Prof. W. D. M. Paton, F.R.S.: "A Theory of Drug Action Based on the Rate of Drug-receptor Combination"; Mr. B. B. Boycott, Mr. E. G Gray and Mr. R. W. Guillery: "Synaptic Structure and its Alteration with Environmental Temperature: a Light and Electron Microscope Study of the Central Nervous System of Lizards".

Institute of Refrigeration (at the Institute of Marine Engineers, The Memorial Building, 76 Mark Lane, London, E.C.3), at 5.30 p.m.—Mr. Carl Munters and Mr. Lennart Lindqvist: "A New Conception in Cooling Tower Design".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. J. Blundell, Mr. A. E. Garside, Mr. R. G. Hibberd and Mr. I. Williams: "Silicon Power Rectifiers".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C 1), at 5.30 p.m —Dr C. E. Ford · "The Inter-relationship of Nucleus and Cytoplasm".* (Seventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

University of London (in the New Physics Building, Imperial College of Science and Technology, London, S.W.7), at 5.30 p m.—Prof. A. B. Pippard, F.R S.: "The *Electronic Structure of Metals*".* (First of three lectures. Further lectures on February 9 and 16.)

Institute of Metals, London Local Section (at 17 Belgrave Square, London, S.W.1), at 6 30 p.m.—Mr. P. G. Forrester: "The Development of Some New Bearing Materials".

University of London (at Wye College, Wye, near Ashford, Kent), at 8.15 p.m.—Prof. R. Brown: "Morphogenesis in Plants".*

Friday, February 3

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W.C.2), at 6 p.m.—*Discussion on* "Recent Technical *Developments* in Eye Movement Recording" opened by Dr. P. A. Merton and Dr. C. Rashbass.

Society of Chemical Industry, Road and Building Materials Group (joint meeting with the Manchester Section, in the Robinson Theatre, The University, Manchester), at 6 p.m.—Mr. D. H. Matthews: "Surface Active Agents in Bituminous Road Materials".

Royal Institute of Chemistry, London Section (joint meeting with the Brighton Technical College Chemical Society, at Brighton Technical College, Brighton), at 7.30 p.m.—Sir H. W Melville, F.R.S.: "Research and Development in D.S.I.R. Stations".

Saturday, February 4

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E 23), at 3.30 p.m.—Dr. F. S. Wallis: "Prehistoric Stone Factories".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist (Principal grade), to take charge of the Biochemical Department of the Group Laboratory, Lakin Road, Warwick—The Group Secretary, South Warwickshire Hospital Group, 50 Holly Walk, Leamington Spa (February 2).

Assistant Lecturer or Lecturer in the Department of Pure Mathematics—The Registrar, The University, Liverpool (February 3).

Lecturer or Assistant Lecturer in Inorganic Chemistry—*The Clerk to the Governors*, Chelsea *College of Science* and Technology, Manresa Road, London, S.W.3 (February 8).

Lecturer in Agriculture (Animal Production); and a Departmental Assistant in *Animal Physiology*, at *the School of* Agriculture, Sutton Bonington—The Registrar, The University, Nottingham (February 4).

Lecturer (with graduate qualifications and wide experience of the paper-making industry) in Paper Technology—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent (February 4).

Research Assistant (with a degree in mathematics or equivalent qualifications, and preferably previous experience of electronic computers) in the Computing Machine Laboratory, to assist in the operation of a computing service on the Mercury and Atlas electronic computers—The Registrar, The University, Manchester 13 (February 4).

Senior or Junior Research Assistant, for the M.R.C. Research *Group in Enzymology in the Department* of Chemical Pathology—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (February 4).

Lecturer (male) in *Education*—The *Principal, Borough Road* College, Isleworth, Middlesex (February 6).

Assistant Lecturer in Philosophy—The Registrar, The University, Leicester (February 10).

Lecturer in Physics; and a Lecturer in Physiological Psychology—The Registrar, The University, Leicester (February 10).

Lecturer in Pure Mathematics; a Lecturer in Applied Mathematics; an Assistant Lecturer in Pure Mathematics; and an Assistant Lecturer in Applied Mathematics—The Registrar, The University, Leicester (February 10).

Lecturer (with special interest in genetics) in Botany—The Registrar, The University, Leicester (February 10).

Lecturer or Assistant Lecturer in Statistics in the Department of Pure Mathematics—The Registrar, The University, *Edgbaston, Birmingham* 15 (February 15).

Reader in Applied Mathematics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (February 15).

Assistant Lecturer (with a good honours degree in either botany or agricultural botany, and a special interest in mycology or plant pathology) in the Department of *Agricultural Botany*—The Registrar, University College of Wales, Aberystwyth (February 18).

Reader in Pharmacology; a Lecturer in Sociology; a Lecturer in Organic Chemistry; a Lecturer in Food Science, a Lecturer in Agriculture (Animal Production); Lecturers and Assistant Lecturers in Civil Engineering and Electrical Engineering; and Assistant Lecturers in Applied Mathematics and Botany—The Registrar, The University, Nottingham (February 18).

Lecturer in Aeronautical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (February 20).

Reader in Applied Mathematics at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 *(February 24)*.

Fellow and Lecturer (mathematician with interests in the field of theoretical physics) in Mathematics—The Rector, Exeter College, *Oxford (February* 25).

Lecturer or Assistant Lecturer in Applied Mathematics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (February 27).

Assistant Lecturer or Lecturer (with qualifications in any branch of pure mathematics and special interests in numerical analysis or mathematical statistics) in the Department of Mathematics; and an Assistant Lecturer (with special qualifications in inorganic chemistry or in physical chemistry) in the Department of Chemistry—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (February 28).

CHAIR OF MATHEMATICS in the Royal College, Nairobi—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (February 28).

LECTURERS OR ASSISTANT LECTURERS (3) IN PHYSICS—The Registrar, The University, Hull (February 28).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, PHYSICS, BIOCHEMISTRY or GEOLOGY—The Registrar, The University, Leicester (March 4).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOW IN CHEMISTRY AND PHYSICS—The Secretary, The University, Exeter (March 5).

ASSISTANT LECTURER IN CHEMISTRY; an ASSISTANT LECTURER IN GEOGRAPHY; and an ASSISTANT LECTURER IN PURE OR APPLIED MATHEMATICS at the University of Singapore, Malaya—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 31).

IMPERIAL CHEMICAL INDUSTRIES FELLOWS FOR RESEARCH IN PHYSICS, CHEMISTRY, COLLOID SCIENCE, BIOCHEMISTRY, ENGINEERING, METALLURGY, PHARMACOLOGY, CHEMOTHERAPY, or related subjects—The Secretary General of the Faculties, The University, The Old Schools, Cambridge (April 29).

DEAN OF THE FACULTY OF HOME SCIENCE, University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, April 30).

GEOLOGISTS (4), to teach in the fields of mineralogy, petrology, petrography, palæontology, stratigraphy, structural geology, economic geology and geophysics—Escola de Geologia, Universidade da Bahia, Salvador, Bahia, Brazil.

MASTER TO TEACH SCIENCE, CHIEFLY PHYSICS AND CHEMISTRY—The Headmaster, King's College, Taunton, Somerset.

RESEARCH ASSISTANT (with an honours degree and preferably some design experience), to investigate high strain fatigue of metals (work suitable for higher degree)—Prof. H. Ford, Imperial College of Science and Technology, London, S.W.7.

REPORTS and other PUBLICATIONS

STRENGTHENING SCIENCE AND TECHNOLOGY

MORE than a year has elapsed since an eminent group met in Paris to discuss ways and means of strengthening science in the Western world. As scientists with executive ability, they had been selected from countries within the North Atlantic Treaty Organization. Motives for bringing together such a study group were prompted partly by the Cold War. However, "even if there were no Soviet menace . . . the demands of the populations of the Western countries for a higher standard of living, for relief from toil and drudgery, for increasing health of body and mind, can only be met by the advance of science and its applications in technology". A report was issued*, and the gist of it appears in a leading article of *Nature* (188, 880; 1960). During December 19–23, countries of the Middle East and North Africa sent representatives to a meeting in Cairo to confer on ways of invigorating science and technology in their respective lands. This was held under the hovering auspices of Unesco, and the conference is reported on p. 362 of this issue of *Nature*. It is of interest to examine critically some of the points which arose from these meetings. Although the participants in the two meetings came from countries which vary widely in the degree of technological development, many of the obstacles encountered are common to all.

The outcome of these deliberations is very cogent and deserves praise. In particular it is heartening to see a resolution from the Cairo meeting (No. 17): "That all efforts and results reached by science should be used solely to help humanity. . . ". It has never been denied that a vast amount of scientific effort is directed according to military considerations. That such research lends an inevitable impetus to the scientific quest for truth is not wholly valid. The effect is of second-order importance—almost trifling, in fact. Perhaps this resolution portends that scientists, realizing the implications, will begin to emerge from their research cartels, exercise a certain political awareness and give a resounding, concerted negation to what amounts to a greater and greater refinement of preparation for cataclysmic war.

To achieve scientific and technological prowess, education is necessary, so much has been said about instructing the would-be scientist. In the Paris meeting it was considered that the logical place to start moulding the scientist and technologist was in the secondary school. That the claims of science and technology were very often subordinated to those of traditional courses in the humanities and law was deplored. Scientific interest should be aroused in the pupil. Quite often this was inhibited by conservative proclivities of teachers devoted to "inert ideas". Pupils should be able to relate the substance of their courses to what science is achieving, hence curricula should be topical. Sir John Cockcroft believes, quite rightly, that to strengthen Britain's science and technology it is more important to do so in the universities than anywhere else at the present time. On January 3 at Nottingham he stated that Britain needs a major new technological university of at least five thousand students if it is to catch up with the U.S.S.R. and the United States. Although during 1958–59 British students of the arts outnumbered slightly those reading science and technology, it seemed likely that by the late 'sixties there would be about twice as many technologists as students of the arts; the absolute number of the latter is not likely to diminish. He also alluded to a point which arose in the Paris meeting, namely, the possible foundation of an Atlantic institute of science and technology which would be a combined effort from countries of the North Atlantic Treaty Organization.

These various points on education for scientists and technologists are well taken. But perhaps a greater stress should be placed on quality rather than quantity. More should not mean worse. Large technological institutes have their place, but, after all, the birth of the Berlioz orchestra has never displaced the æsthetic need for the string quartette. The dangers of egalitarianism and conformity in large institutions are immense. In his book, *Teacher in America*, Prof. Jacques Barzun of Columbia University, New York, has pointed out the sorry plight of education in the United States. He feels that education should be a hand-to-hand affair. He refers to the 'preceptorial' system used successfully at Princeton University. This is a small university relative to the massive institutes of technology, but its educational calibre, both in the sciences and in the humanities, is unsurpassed in the United States. The preceptorial system is similar in principle to the tutorial system of Oxford and Cambridge, and possibly a few other universities, whereby students receive instruction in small groups. Standards of all degrees should be kept high, otherwise they become meaningless. It is quite revealing to examine some theses toward research degrees—their tortuous manipulation of symbols, numerous data, wealth of bibliography, but sadly a paucity of ideas. One is tempted to say with Virgil:

> "Why not apply yourself to useful tasks,
> Plait wicker crates and baskets of soft reeds?"

The probing spirit should be respected for what it is; not make a passport to probe, appended to it, a *sine qua non*. Perhaps atmosphere is lacking, and this could be partly ascribed to the passion for the research 'project'. The meditative approach was used by great men of science in the past—"What interesting questions does Nature pose and what is the minimum amount of experimental equipment needed to answer them ?"—and it resulted in great works. It is well worth a visit to the Cavendish Laboratory to see with what little equipment so much was accomplished.

---

* Increasing the Effectiveness of Western Science. Pp. iii+19. (Brussels: Fondation Universitaire, 1960.)

The criticism levelled at academic institutions which encourage the humane tradition in education is perhaps not entirely called for. Science should not displace the humanities but be an adjunct and partner. The scientific method is one way of approaching truth progressively—there are other ways, equally laudable. An educated man should have reasonable command over all these. How disquieting to envisage a growing host emerging from technological institutes, all thinking in the same way, all with similar utterance—in effect, a band of æsthetically impervious, socially unaware, but adept barbarians who will not deem any knowledge worthy unless it be formulated exactly. It is Anton Tchekov who tells Grigorovitch he had come to the conclusion that "an artist's instinct may sometimes be worth the brains of a scientist, that both have the same purpose, the same nature, and that perhaps in time, as their methods become perfect, they are destined to become one vast prodigious force which now it is difficult even to imagine".

That science syllabuses are kept up to date and the pupil's enthusiasm stimulated by emphasizing present scientific achievements is necessary. However, it is well to point out to the pupil what fundamental scientific thought means as opposed to the technological aspects. His imagination is captivated easily by the glamour of rockets and satellites. This to him is science *par excellence*. However, if he were to realize that it is the genius of Newton's laws plus a fuel of large enough specific impulse, developed with abundant funds, which enables 'rocketeers' to 'aim at the stars', it would sharpen his critical appreciation of scientific merit.

The dilemma faced by a research worker seeking specialized information in his field was discussed by the group in Paris and at the meeting in Cairo. The recent decline in adequate documentation was blamed on "the mushroom growth of scientific publications" and on poor methods of classifying publications. Unesco and allied organizations will attempt to improve the situation by unifying editorial practice, by instituting a single international indexing system, by requesting authors to submit abstracts with their research articles and by discouraging new publications. How avid scientists and engineers are to-day to get into print ; to place their morsel on the altar of fame ! Inundated by this spate of material of greater or lesser virtue, one cannot help but yearn for the modesty of the Darwins and Faradays of the past. To the solutions which Unesco will attempt, it seems appropriate to add a wily suggestion given by Mr. L. J. F. Brimble during an address to the Royal Society of Edinburgh on January 11, 1954. He felt that every scientist intending to publish research should be posed with the following questions : "(1) Are you sure you have said what you want to say ? (2) Have you said it in the minimum number of words ? (3) Is it worth saying at all ?"

EVOLUTION

Evolution After Darwin

Edited by Prof. Sol Tax. Vol. 1 : The Evolution of Life—Its Origin, History and Future. Pp. viii+629. Vol. 2 : The Evolution of Man—Man, Culture and Society. Pp. viii+473. (Chicago : University of Chicago Press ; London : Cambridge University Press, 1960.) 80*s*. net each volume.

Evolution

Its Science and Doctrine—Symposium presented to the Royal Society of Canada in 1959. Edited by Thomas W. M. Cameron. ("Studia Varia" Series, Vol. 4.) Pp. xi+242. (Toronto : University of Toronto Press, 1960. Published for the Royal Society of Canada.) 40*s*. net.

THE first of these books (Vols. 1 and 2) forms part of a series of three volumes of Darwin entennialc essays written by well-known scientists as the basis for discussions which took place between the writers during the Darwin centennial celebrations at the University of Chicago, 1959. The third volume, *Issues in Evolution*, is not included in this review. Altogether there are 42 essays and some of them are very long, up to 80 pages and with about 200 references. These essays are quality writings, perhaps designed more for experts than for general readers, who would require a large background knowledge to appreciate all of them.

About a year ago I heard a publisher publicly declare that evolution as a topic of concern was dead. I suppose this is true in terms of the old Darwinian controversies. It seems that there is now a more settled and intelligent view of the matter—the theory has been assimilated into the general intellectual background. The publisher's statement is certainly not true when we turn to biological literature, and the symposia presented by the books reviewed are evidence enough of the professional interest in evolution. There are still plenty of teaching and research biologists who would answer the question "Is evolutionary theory important ?" with "Yes, I suppose so". They accept it, but are not particularly stimulated by it. It is precisely to people like this that the present symposia should be of importance, if only because these essays range over such a very wide field. The essays will either provoke the 'bandwagon' biologist's anger or his acceptance, but they will not leave him unmoved.

These essays show unmistakably how intertwined all the sciences are. Biology is not just the study of the grosser aspects of plants and animals, but now takes in all empirical approaches to knowledge in its phenomenological aspects. This all springs from the uniqueness of man, from mind if you like, but, as some of the essays show, this knowledge stops there. A disheartening feature of the books as a whole is that no indication is given of a further step in the study of life, particularly in relation to man, where much of the cultural tradition of the older scholasticism, which rendered possible the development of the newer scientific scholasticism, is ignored. An essay by Teilhard de Chardin, if it had been possible, or by someone of similar cosmic outlook, would have completed the story of evolution as set out in these two volumes. An essay taking in man as a biological and as a spiritual creature would have set a truer balance between the essays. The lack of such a balance has destroyed the harmony of the whole plan, and this disharmony is emphasized in several of the essays in which a materialistic approach (as distinct from a necessary mechanistic approach) is maintained. Other essayists, such as C. H. Waddington, are not so dogmatic. He contends, reasonably enough, that the evolutionary theory does not critically answer the question of the acceptance or rejection of theism or atheism. It must be settled in some other way, and so he is not concerned with it. But if evolution is the process basic to the whole of the cosmos, and it is to this view that a wider view of evolution leads, then the question of theism or atheism is of the utmost importance, for either evolution leads to one or the other concept or the process of evolution lacks meaning for man and is relatively unimportant.

While all the writers justifiably emphasize the importance of the works of Charles Darwin and many of them seek explanations through natural selection, some writers tend to discuss the operation of selection in fields where there is no evidence of its operation. An interesting feature of the books as a whole is that the importance of selection is not now so over-emphasized, except perhaps by a few extreme selectionists, but the importance of a balance between the well-known factors of evolution is acknowledged.

In the essays on the evolution of man, L. S. B. Leakey gives an interesting account of the new genus *Zinjanthropus* and its importance. But in some of these essays it is clear that there is a general attempt to lessen the Cartesian split between body and mind and hence between man and lower animals. The method of doing this would seem to be unsound, for man is played down as it were, his really important attributes are glossed over in favour of finding him a place in a zoological classification, while at the same time the animal is played up until we are nearly led to think that there is scarcely any fundamental difference between man and animal. But, to a non-Cartesian who still holds to the spirit of the Thomists that the phrase *animal rationale* is meaningful, the evidence for the smallness of the gap between man and animal does not seem excessively strong. Although to some biologists the term 'man' may be a confounded nuisance, to other people it is far more than a colloquial word. I was beginning to think that perhaps the infra-human hominoids were more human than I myself, until I was brought back to earth by recalling a sentence of Humphrey J. T. Johnson that there is a wider difference "between a man and a gorilla than between a gorilla and a daisy. The one is as incapable as the other of creating civilization".

All these essays are interesting and, above all, most stimulating. They are full of sound information and points of view and cover most aspects of evolutionary theory and its implications, but not all. An important essay which is missing from this work is one which discusses the validity of the fundamental assumptions of all evolutionary theory, the value of the mathematical models, particularly in the genetical field and the tautology of selection. There are biologists, such as W. R. Thompson, who doubt some of these assumptions, such as that embodied in G. G. Simpson's twisted phrase of "the genetical relationships that are reconstructed as phylogeny". Indeed, Bernard Rensch has contributed a very valuable essay on the laws of evolution which would have better earned its *droits de cité* if it had been preceded by an account of the methodological bases of evolutionary theory. A critique of evolutionary theory has long been needed and the opportunity for its production was given by these centennial symposia, but, at least in these books, the opportunity was lost.

Evolution: Its Science and Doctrine is also the result of a symposium on evolution organized by the Royal Society of Canada to commemorate the Darwin centenary and held at the annual meeting of this Society in 1959. The book contains twenty essays, all by Canadians. These essays do not cover such a wide field as those in the Chicago symposia, and most of them are straightforward accounts of biological, geological, biochemical, sociological, philosophical and cosmological aspects of evolution. They are less for the expert than for the general trained reader. They are non-controversial except for one of them. This last essay gives a biochemical outlook on evolution which is so dogmatically materialistic and narrow in its interpretation as to lower the intellectual level of the book as a whole. It is, however, offset to some extent by an essay in French on philosophy and evolution. It is unfortunate that this symposium did not include an essay on the evolution of man. In general this is an interesting book containing much useful information and with a balanced outlook on evolutionary matters.

P. G. FOTHERGILL

A FARRAGO OF EARTH HISTORY

Biography of the Earth

Its Past, Present, and Future. By Prof. George Gamow. Revised edition. Pp. xiii+242+27 plates. (London: Macmillan and Co., Ltd., 1959.) 35*s*. net.

IN his presidential address at Cardiff to the British Association Sir George Thomson emphasized the obligation of "the popularizer to take anxious care lest in trying to simplify he make statements which are simply untrue". This book is a most unhappy example of not taking care. Prof. Gamow has a well-deserved reputation as a popularizer, and I have myself had so much entertainment and pleasure from some of his books that it was with real distress that I found in the first edition of this book (1941) so much that was misleading and irresponsible. One trivial example sent a wave of hilarity around the geological world: on p. 145 Gamow had written "the name 'Cambrian' indicates simply that the deposits of that period were first discovered and studied in Cambridge-shire (England)". In the 'revised' edition of 1959, p. 145 remains exactly the same, word for word, as before. On the same page, and the next, we still learn that "micaschists" are ordinary sandstones "metamorphized". Indeed, nearly all the pages are reproduced without change. The main alteration is in the treatment of the origin of the solar system.

Collision hypotheses are now abandoned in favour of Weizsäcker's modified version of the Kant–Laplace hypothesis. Two or three pages have been revised to include the possibility that life began with the natural synthesis of amino-acids and their eventual linking together as proteins. Piltdown man is disowned as a fake. The age of the Earth is increased from 2,000 m.y. to 5,000 m.y.; but no mention is made of the magnificent work of Claire Paterson and his co-workers; the credit all goes to the rubidium–strontium method, which we are told gives more reliable results than those based on the decay of uranium, and has "more than doubled the estimated age of various rocks". Despite this, however, it is still stated that 1,500 m.y. "definitely represents the upper possible limit" for the age of the oceans. "Before that time all the Earth's water must have existed solely in the form of atmospheric vapour."

Corresponding to these erroneous ideas, Gamow tells us that the first extensive period of sedimentation was followed by the Laurentian revolution (about 1,000 m.y. ago). Because these layers of sediment contain but little salt, we are asked to believe "that sea water must have been quite fresh at that time". Not a word about the older orogenic belts, going back to 3,000 m.y. and beyond. Not a word about granitization, one of the most important processes affecting the Earth's biography. Seismologists will be depressed to learn that according to Gamow "the outer layer of the crust consists of a layer of granite extending to a depth of from 50 to 100 kilometres. This granite layer rests on a layer of heavier volcanic material, known as basalt, which is probably several thousand kilometres deep". Nowhere do we find a word about the Moho discontinuity or the astonishing thinness of the oceanic crust. The exploration of the ocean floors, which is becoming one of the major achievements of our time, is passed over in silence. A certain amount of continental drift is admitted, but with the proviso that it must have ceased at an early stage of our planet's history, shortly after the birth of the Moon, which stripped away the granite layer from the region that is now the Pacific basin. Not a word about palæomagnetism. Not a word about the hundreds of miles of relative movement along the San Andreas and other great faults. Not a word about the discovery that these movements have been speeding up—on average—during the last 100 m.y. or more and that we are now living in a phase of exceptionally intense geological activities. Instead, Gamow thinks "we are now living during one of the relative lulls in activity". The cause of Earth movements and mountain building is still referred to "the steady cooling and shrinking of our globe". Not a word about phase transformations and the exciting possibility that the Earth is expanding.

So one could go on. Prof. Gamow has failed to realize that the earth sciences are progressing at an ever-accelerating rate. New knowledge is continually disrupting parts of the old framework, and the geologist has to assess the bearing on his subject of the interplay of almost daily discoveries in many branches of science besides his own. Prof. Gamow has simply not taken the trouble. It is not good enough to take a pot-boiler that was thoroughly bad from the start, revise a few pages, stick on the date 1959, ignore all the unprecedented advances made since the end of the War (except for the age of the Earth) and then to claim that "the revised edition embodies the currently accepted theories", which the author believes are "now here for good". I am sorry to be so severe, but a reviewer's first loyalty must be to his subject. I know that Prof. Gamow could do very much better if he would take the necessary trouble and then re-write the book and have it examined as he goes along by a competent geologist. Perhaps he will be inspired to make amends in this way by a pregnant remark made by Igor Stravinsky in 1958: "We all feel we are right; but we felt the same way twenty years ago and today we know we weren't always right then"

Arthur Holmes

ACHIEVEMENT IN THE GLASS INDUSTRY

Pilkington Brothers and the Glass Industry
By T. C. Barker. Pp. 296+20 plates. (London: George Allen and Unwin, Ltd., 1960.) 40*s.* net.

THE Pilkington glass enterprises began in 1826 when William Pilkington joined his brother-in-law Peter Greenall and two other men in the purchase of a small glass-works in St. Helens. This works manufactured window glass by the crown process, that is, the spinning of an opened-out bulb on the end of an iron so that a flat circular disk was formed. The disk was of uneven thickness, the centre part where it had been held on the iron being the bull's-eye sold cheaply at the time, but now sometimes made specially to provide a false appearance of antiquity. Soon William's elder brother joined him, and in 1829 the two bought out the other partners. William Pilkington's business ability was of great importance; he toured the country making contacts and obtaining orders, and the building boom of the 1830's helped the young firm to prosper. To this day the Company remains a private, family one.

The activities of the Firm have always been marked by very sound judgment in the choice of developments which were worth backing. During a depression in the industry around 1840 the improved cylinder process for sheet glass, which their rivals Chance's had been developing for some years, was introduced and the initial troubles had been overcome when the market boomed once more. Much later, in 1921 the development of the continuous process of manufacture of plate glass was undertaken in co-operation with the Ford Motor Co., and Pilkington's were ready to meet the new market which came with the expanding car industry. This fascinating story of the Ford–Pilkington co-operation is told in appendix 8. In 1919, C. W. Avery began to experiment in Detroit with a continuous process for plate glass. In 1919, he wrote: "We sent for a little crucible from Germany. It was about a month before we got the crucible back and it only held about a pint". By December 1921 1,500,000 dollars had been spent and the progress made impressed Pilkington's representatives so much that agreement was reached for co-operation in the further development of the process. Pilkington's, with their extensive knowledge of melting glass in tank furnaces, were then able to make a very important contribution. The continuous grinding and polishing plant was first put into use in 1923. In this process a continuous ribbon of glass nine feet wide issuing over a weir from a tank furnace passes through the annealing lehr and then under the grinding heads. In 1935, the twin grinder, a Pilkington development, which grinds both sides of the ribbon glass simultaneously, began operation at Doncaster.

Although there were no formal research laboratories as such until 1938, the firm was well able to make use of technical development. Cecil Pilkington was an Oxford graduate in natural sciences: in 1901, assisted by Leonard Lackland, a graduate of Liverpool, he introduced recording pyrometers and with their aid reduced the annealing schedule from 4 days to 4 hours. Electrical power was introduced in 1893; vacuum sucker pads were first used for handling plate glass in 1913. This present year, 1961, will see the opening of the 250,000 sq. ft. laboratories at Lathom Park about ten miles from St. Helens. Curiously, the firm appears to have lagged behind in the development of sheet glass, that is, flat glass which is made by a process which produces sufficiently good surfaces to require no subsequent grinding or polishing. The developments in the Fourcault continuous sheet process in the early 1900's had been watched carefully, but in 1928 sheet glass was still being made in St. Helens by the machine-drawn cylinder process and the production had to be subsidized by other activities. In 1930 interest was shown in the Pittsburgh Plate Glass Company's sheet process and by 1933 all sheet glass manufactured at St. Helens was made by this process ; since that time Pilkingtons have made important developments in this process. An entirely new development announced a year ago is the 'float process' which produces continuously, without grinding and polishing, flat glass with the quality of plate glass, on the development of which £4,000,000 was spent.

The present book is primarily an economic history of the Company ; the rather random notes of developments noted in reading the book and referred to in the previous paragraphs show that there is also a most interesting outline of the technical progress. As a chapter in economic history the book appears well done. There are more than 780 references to original sources, including Board minutes and documents in the Company's archives. It is an impressive story of a family which for four generations has produced efficient and shrewd business and technical men ; enlightened employers, with time not only to build and run one of the largest industrial concerns in Britain but also to devote much of their time to public service. In a statement issued by the founders Richard and William Pilkington to the work-people during some labour troubles in 1845 is the following, "It is our duty and our study, and we have always considered it our interest, to promote the happiness and welfare of all . . .". The story stops before the present generation took office, but they are carrying on the traditions in a manner worthy of their forbears.

R. W. DOUGLAS

INDIAN MONOGRAPHS ON ALGAE

Cyanophyta

By Dr. T. V. Desikachary. (I.C.A.R. Monographs on Algae.) Pp. x+686. (New Delhi: Indian Council of Agricultural Research, 1959.) 72*s*

Zygnemaceae

By Dr. M. S. Randhawa. (I.C.A.R. Monographs on Algae.) Pp. 478. (New Delhi: Indian Council of Agricultural Research, 1959.) 50*s*.

THESE two books are concerned mainly with freshwater algae which, in Britain, are of economic interest only to those concerned with the supply and purity of water. When present in large numbers they are generally considered as pests. In other countries, notably more or less tropical ones, they form the basis for a supply of much-needed protein in the form of fish which feed directly on them or through food-chains the few links of which ensure a relatively efficient secondary production. They can also be used in a simple, effective process of sewage purification ('oxidation ponds') and may increase the efficiency of solar salt works. Several of the Cyanophyta described fix nitrogen and play an important part in the cultivation of rice. Since rice is the staple food of a large part of the human race, and poverty in nitrogen a common feature of tropical soils, such algae are of great economic importance. Lastly, the possibility of mass culture of algae for direct use as food is being studied by biologists in many countries. Therefore the Indian Council of Agricultural Research is to be congratulated on starting an ambitious series of monographs which will eventually cover all algal groups. English is the international language of much of Asia and Africa, while the world-wide distribution of most freshwater algae makes these books of value to all phycologists.

These first two volumes set a good standard for the whole series. They are well set out and printed, richly illustrated, contain few misprints or misstatements and their cost is reasonable. They are more than Floras because there are sections on structure, reproduction, biology and general classification.

The taxonomy and nomenclature of algae are today in a confused state. Therefore each author has had to decide which 'system' to follow or to provide his own. Both are experienced workers, and, in the main, they use the classical system exemplified by *Die Susswasserflora Deutschlands, Osterreichs und der Schweiz* and Rabenhorst's *Kryptogamenflora*, though systems advocated by other authorities are described. It is disappointing that they do not criticize these diverse viewpoints. The non-specialist may also believe that the species and genera are clearly understood when, for the Cyanophyta at least, there are very few for which this is the case.

The first 75 pages of Dr. Desikachary's *Cyanophyta* cover structure, reproduction, classification and biology, and make clear once again how ignorant we are about these algae, notably concerning heterocysts, gas-vacuoles and mucilage. The next 545 pages describe all the taxa known from India, including ten new to science. The book concludes with a list of about 800 references and a rather scanty index.

Matters which may be criticized are omissions of some of the ecological and physiological features of these algae, too little consideration of the important work on micro-anatomy based on the use of the electron microscope, and the statement that the separation of *Petalonema* from *Scytonema* "appears to be convenient" ; modern work shows that this is incorrect. There also seems to be a lack of appreciation of the strong probability that some species of *Dactylococcopsis* are in fact green algae (*Ankistrodesmus*).

Dr. Randhawa's account of the Zygnemaceæ is more ambitious, for it covers the flora of the whole world. As this is a smaller and more coherent group than the Cyanophyta such a treatment is easier, and it adds considerably to the value of the book. In the first 100 pages a general consideration of these algae is given on similar lines to that appearing in the volume on Cyanophyta. A useful feature here is the section on their distribution in India in relation to the seasonal climatic changes, though it would be preferable to have altitudes, temperatures and rainfall expressed in metric units. There follow some 300 pages of keys and descriptions of species with an index (there is no general index) and a good bibliography.

Valuable features are the author's own numerous records of the occurrence of the species in India, so that one knows he has studied them himself. It is a pity he has not made more original drawings, because some of the illustrations chosen are not very satisfactory. Dr. Randhawa, like most modern workers on the group, has little use for infra-specific categories. This is in marked contrast to the other major group of the Zygnemales, the desmids, where specialists describe innumerable varieties and forms.

Although the important work of Dr. M. B. E. Godward on the cytology of *Spirogyra* is mentioned (p. 21) it is ignored in the section on the nucleus (pp. 53–59); consequently, the taxonomic potentialities of nuclear and chromosomal structures are also ignored, as are the new species she has described. In the section on Lloyd's discovery of contractile vacuoles in the gametes of *Spirogyra*, Matvienko's finding that these may only appear in the male gamete is omitted. The maps are puzzling. Naturally, like most maps covering the distribution of freshwater algae, these show mainly where phycologists have worked, but some features are misleading. Thus there are apparently only two species of *Zygnema* and four of *Spirogyra* recorded for England, whereas, in fact, about eight times as many are recorded. It is correctly stated on p. 261 that *Zygogonium ericetorum* has been recorded from every continent, but reference to map *H* gives the false impression that it is unknown in Europe outside England, in Asia outside India and China, in Africa outside the Union of South Africa and in America outside the United States.

Such criticism of these books as seems necessary does not alter the fact that they are considerable achievements and deserve the wide circulation they are likely to obtain. J. W. G. Lund

EUROPEAN SPIDERS

Die Tierwelt Deutschlands und der Angrenzenden Meeresteile nach Ihren Merkmalen und nach Ihrer Lebensweise

Begründet von Prof. Dr. Friedrich Dahl. Weitergeführt von Maria Dahl und Prof. Dr. Hans Bischoff. 47 Teil: Spinnentiere oder Arachnoidea (Araneae). XI: Micryphantidae—Zwergspinnen. Von Dr. Hermann Wiehle. Pp. xi+620. (Jena: Gustav Fischer Verlag, 1960.) 107.65 D.M.

This volume completes a series of monographs on the German spider fauna which began in 1926 with Dahl's *Salticidae*. The group of spiders described in this volume, known to the British araneologists as the sub-family Erigoninae, has been elevated to family rank by Dr. Wiehle under the name Micryphantidae. The text covers 615 pages, has 1,147 figures and describes 144 species in 74 genera. Together with the previous volume on the Linyphiidae, Dr. Wiehle has completed a monumental work which will stand as an authoritative text on European spiders for many years. Apart from the British Ray Society monograph by G. H. Locket and A. F. Millidge published during 1951–53, the present volume is the only modern work dealing with the difficult taxonomy of a very large family of tiny spiders, of which more than half are between 1 and 2 mm. in length. The German fauna is of particular interest to the British student because it includes both western and eastern European species, whereas the British fauna (144 species in 68 genera) is predominantly western and northern. Adequate taxonomic works on the Linyphiidae and Micryphantidae have become especially important in recent years because of the development of ecological studies on spiders, particularly those species in the litter and ground vegetation, most of which are members of these two families.

Wiehle's subdivision of the Micryphantidae into four sub-families follows closely that of Petrunkevitch in 1928. Sub-families Masoninae and Peleoopsinae have been generally recognized since they were proposed by Simon in 1884, and Wiehle has preferred Simon's name Walckenaerinae for the third sub-family instead of Petrunkevitch's Gonatiinae. The fourth sub-family, Erigoninae, remains, although there has been a redistribution of genera between it and the Walckenaerinae.

The genera and species keys owe a great deal to previous work by J. Denis in France and A. F. Millidge in England. The numerous figures are clearly drawn and an invaluable aid to identification. The list of references includes 187 titles, but omits that of Engelhardt (1958) which is referred to on page 1. Eric Duffey

NEUROSURGERY IN WAR-TIME

Neurosurgery

Vol. 2. Edited by R. Glen Spurling and Barnes Woodhall. (Medical Department, United States Army. Surgery in World War II.) Pp. xxvi+705+12 plates (283 figures). (Washington, D.C.: Office of the Surgeon General, Department of the Army, 1959. For sale by the Superintendent of Documents, U.S. Government Printing Office.) 7 dollars.

The previous excellent volume on neurosurgery in this series dealt with the organization of the specialty in the United States Army Medical Service during the Second World War and with head injuries; the present, and larger one, deals with spinal and peripheral nerve injuries.

The section on spinal injuries deals with every aspect of missile wounds of the spinal cord, with particular emphasis on details of nursing care, organization of evacuation and the urological problems presented by these patients. In the latter connexion, it is of interest that closed vesical drainage with manual control was preferred to automatic (tidal) drainage. An excellent account is presented of the work carried on in the paraplegic centres established in the United States to care for these terribly handicapped men, and the description of the financial and other assistance provided to resettle them in their homes and at work is impressive. The goal of those in charge of these centres is well summarized in the aphorism "Having added years to the lives of traumatic paraplegics, we must now, above all, add life to their years".

Peripheral nerve injuries are considered fully from anatomical, physiological and surgical points of view. Other chapters deal with injuries of these nerves combined with serious soft tissue, bone and vascular damage. Causalgia and its treatment are fully discussed. A most valuable chapter correlates the clinical features with the pathological changes, gross and microscopic, occurring at the site of injury in a series of more than 200 peripheral nerves.

In both this volume and that which preceded it one is constantly aware of the tremendous organizing ability which provided and so successfully staffed the large number of neurosurgical centres in the United States and abroad during the Second World War. This organization went further, however, in uniting the centres into one great team with the experience, therapeutic advances and research findings at one centre being made known to all through bulletins, meetings and the visiting consultants. The advantages of such an organization over that existing at the time in Britain need no emphasis—here, large numbers of neurosurgical (military and civilian) casualties were cared for in civilian hospitals, by neurological surgeons in some, orthopædic surgeons in others, each group working in relative isolation, some with an inadequate staff and without facilities for research or discussion of their problems with other groups interested in the field. While such a state of affairs was of course not invariable, it did exist. Not the least valuable contribution of these volumes from the United States could be the guidance they might provide concerning the organization of war-time neurosurgical services in Britain should the need for this again arise. J. E. A. O'Connell

BERYLLIUM

Beryllium

By G. E. Darwin and Dr. J. H. Buddery. (Metallurgy of the Rarer Metals, No. 7.) Pp. ix+392. (London: Butterworths Scientific Publications, 1960.) 70*s*.

POSSESSING, as it does, low density, high-elastic modulus, moderate strength and good oxidation resistance, beryllium would be an attractive structural material were it not for its low impact strength and high notch sensitivity. Because of these limitations, beryllium has been important mainly as a minor addition to alloys based on other metals, until the advent of nuclear energy made new demands on the metallurgist and necessitated a re-appraisal of the so-called rarer metals. Because beryllium has low atomic weight and very low absorption cross-section for thermal neutrons, both the metal and its oxide, beryllia, are suitable for use in reactors.

Intensive research and development work in recent years has made possible the use of beryllium for the canning of nuclear fuel elements. Much work had to be done before this stage was reached, however, and the book now under review gives a timely summary of available knowledge. All aspects of the metallurgy of beryllium are discussed including the occurrence of beryllium-bearing minerals; the extraction, production and fabrication of the metal; its physical, mechanical and chemical properties; its alloying behaviour and its nuclear properties. A chapter is devoted to beryllia, another to the "Health Hazards and Their Control" that have complicated recent work on both metal and oxide, and a useful appendix is devoted to the determination of oxygen in beryllium.

A monograph on a single metal is generally expected to refer to every relevant paper of note, and the authors have clearly borne this in mind. References are numerous throughout, frequently with just a short sentence about each paper, and there are occasions when more critical comment would have been welcome. As might be expected, this applies mainly to those parts of the book which are concerned with aspects of the subject outside the authors' personal experience. The sections more directly concerned with the production and fabrication of beryllium for nuclear energy, and with the properties of most direct relevance, are written in a much more authoritative manner, and the volume will be welcomed by all those working in this field.

If only the problem of brittleness could be overcome, beryllium would be of the greatest interest to aircraft designers. Those aeronautical engineers who are already discussing the potentialities of the metal should welcome this comprehensive treatment, and they should find the chapter on the ductility of beryllium of special interest. The book is nicely produced and well illustrated and is a useful addition to metallurgical literature. A. G. Quarrell

RARE-EARTH CHEMISTRY

The Chemistry of Yttrium and Scandium

By Dr. R. C. Vickery. (International Series of Monographs on Inorganic Chemistry, Vol. 2.) Pp. vii+123. (London and New York: Pergamon Press, 1960.) 40*s*. net.

IF the purpose of a monograph is to present the reader with a concise, critical and systematically presented résumé of knowledge in a particular field, and to spare him so far as possible the need to refer to the original literature, this book is unsuccessful. Scandium and yttrium are commonly discussed together with the lanthanons, even though in all their properties they display the behaviour expected of elements in Group IIIA of the Periodic Table. It is, in fact, impossible to consider the chemistry of yttrium, in particular, without continual comparisons with rare-earth chemistry, and, except at the level of detail and completeness found in Gmelin's *Handbuch*, it is debatable whether the elements justify a book to themselves.

Following a rather diffuse discussion of the history, natural occurrence and atomic properties of both elements, the author sets out to treat the isolation and the chemistry of each in turn. In matters that touch on Dr. Vickery's extensive practical experience of rare-earth chemistry—the (curiously old-fashioned) treatment of their minerals, the extraction and the analytical chemistry of scandium and yttrium—the reader is overwhelmed with facts and details of procedure. Other chapters that should clearly set out the chemical and physical properties, crystal structures and thermodynamic data for their compounds are sketchy, confusing in arrangement and, in parts, apparently ill digested. Plates, diagrams and textual statements are too often quite uninformative, and the whole lacks a certain coherence. Much of it might have been written thirty years ago, and even such separation procedures as ion exchange receive a disproportionately small allowance of space. On the credit side the author has assembled a considerable (but not a complete) bibliography, though the reader's confidence in the reliability of references may be shaken by other evidence of exceptionally careless proof-reading and preparation of the manuscript. Counting obvious typographic errors, mis-spelt names, omission of units and downright factual blunders, I noted corrections on at least 29 of the 116 pages of text. A purist would want to alter the lamentable English style on many more. The book has a limited usefulness. J. S. Anderson

Haldane of Cloan

His Life and Times, 1856–1928. By Dudley Somner. Pp. 448+12 plates. (London: George Allen and Unwin, Ltd., 1960.) 42*s*. net.

In writing this new life of Lord Haldane, Mr. Somner had access to much material not available to Sir Frederick Maurice; but though his book gives a vivid and well-balanced picture of Haldane it does no more than General Maurice's book to solve the enigma of Haldane, and throws scarcely any fresh light on his achievements, particularly in those fields of most interest to the scientist. Of Haldane as an administrator, an educationist or a philosopher we are shown, in fact, less rather than more: the *Machinery of Government* report is dismissed all too briefly, and the reader of Mr. Somner's book is given no indication of the extent to which Haldane's thought has influenced subsequent investigations into the organization of government. The new material has gone rather to expand the political picture of the times in which Haldane moved, and of his later years particularly we are told singularly little.

Mr. Somner frankly acknowledges his debt to General Maurice, but the whole structure of his book is on different lines, without, however, contributing anything fresh, except perhaps new light on particular episodes or the general political background. Much of Haldane's thought, not only in administration but also in education, and more especially university education, and on the organization of research, for example, is, however, remarkably relevant to the issues of to-day, and what one would have looked for in any new life of Haldane on this scale is some reassessment of the significance of his thought and work in such fields. No hint is given, however, of Haldane's part in stimulating the institution of the University Grants Committee, or of the research grants of the Department of Scientific and Industrial Research, although his work for adult education is recognized. To the scientist who has any knowledge of Haldane's work or thought in such fields it may well seem that an invaluable opportunity has been missed of re-examining critically Haldane's work and thought as a strategist, as an educationist, as an administrator or as a philosopher in a context which is as relevant to the issues of to-day as a generation ago. It is in such a context, moreover, that the stature and achievements of such a man as Haldane are most apparent R. Brightman

Trans-Antarctic Expedition, 1955–1958

Scientific Reports. No. 4: Tides at Shackleton, Weddell Sea. By J. G. D. Pratt. Pp. 21+2 plates. (London: Trans-Antarctic Expedition Committee, 22, Gayfere Street, S.W.1, 1960.) 12*s*. 6*d*.

A British contribution to tidal knowledge in the Antarctic is always an event, and *Tides at Shackleton* is no exception. Piquancy is added to the article not only by the comparatively unusual method of observation—by Worden gravimeter on a freely floating ice shelf—but also by the refreshing and often humorous method of presentation. The ingenuity required to improvize and maintain such a sensitive instrument under the physical conditions encountered, so as to obtain a sufficiently long series of observations for analysis, is greatly to be admired, as also is the painstakingly careful treatment of the data. After having analysed these data by standard methods of tidal analysis, and obtained results of which any tidologist would be proud, the author then proceeds to devise what he calls a 'least squares' method of analysis (all standard methods of tidal analysis are fundamentally based on least squares theory) and produce harmonic tidal constants seriously in discord with the 'standard' results. Pratt gives his reasons for this as being the existence of spurious oscillation with periods near 24 hr. and 40 hr. But while a spurious diurnal oscillation can seriously affect the diurnal constants in a tidal analysis, neither this nor the 40-hr. oscillation could affect the phase-lag of M_2 by 75°. Rather than force what are believed to be transient oscillations into the mould of harmonic constituents by a least-squares method, it would be better to examine the residuals obtained after subtracting a predicted tide (from the results of tidal analysis) from observations. There must be an error in the 'least squares' analysis for M_2 (and probably also for O_1), and, in view of the paucity of tidal data in the Weddell Sea and Mr. Pratt's own sterling efforts, this should be exposed.

J. R. Rossiter

Industrial Fatty Acids and Their Applications

Edited by E. Scott Pattison. Pp. vi+230. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1959.) 56*s*. net.

This book is edited by Mr. E. Scott Pattison, manager of the Fatty Acids Producers' Council, New York, and consists of a series of contributions by senior consultants of a number of major chemical firms in the United States on the industrial production and main usages of the varied chemical derivatives of fatty acids.

Some of these products have an annual commercial utilization of many millions of pounds; their value as detergents, plasticizers, food additives, cosmetics, etc., are clearly and concisely described. Special mention is made of the recent increased commercial interest in 'tall oil', a rosin/fatty-acid by-product of the paper-making industries. The purification, chemical nature and usages of derived fatty acids are given extensive treatment in the text, as also are the industrial processes involved.

The interactions of fatty acids with varied chemical reagents are given detailed treatment and chemical equations are employed extensively to illustrate the fundamental reactions occurring.

This book will prove of great interest to the chemists and chemical engineers who wish to keep abreast of modern development in the industrial field of fatty-acid technology. It should also prove of absorbing interest to the academic organic chemist.

D. T. Lewis

Space Research

Proceedings of the First International Space Science Symposium, Nice, January 11-16, 1960. Edited by Dr. Hilde Kallmann Bijl. Pp. xvi+1195. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1960.) 170*s*

The First International Space Science Symposium was held at Nice in January 1960, under the auspices of the Committee on Space Research. The volume under review thus has a historic character as well as being an exceptionally well-edited proceedings of the symposium printed and bound to the same high standard.

An account of the symposium was given in *Nature* on June 4, 1960, so no more than the section headings will be given here: (1) "The Earth's Atmosphere", (2) "The Ionosphere", (3) "Tracking and Telemetering", (4) "Solar Radiation", (5) "Cosmic Radiation", (6) "Interplanetary Dust", (7) "The Moon and the Planets". Radiation from celestial sources is included under "Solar Radiation". The 100 papers cover mostly the two years of space research from the launching of the first artificial satellite to the time of the conference. Since another symposium is planned by the committee for next spring, there can be little doubt that this volume is just the beginning of an important series, and it is to be hoped that the future conferences and their proceedings will enjoy the same success as the first.

R. L. F. Boyd

Health Physics in Nuclear Installations

Symposium organised at the Danish Atomic Energy Centre, Risø, 25–28 May, 1959. Pp. 410. (Paris: Organization for European Economic Co-operation, European Nuclear Energy Agency; London: H.M. Stationery Office, 1959.) 2,500 francs; 37*s.* 6*d.*; 6 dollars; 21.30 D.M.

This volume contains thirty-two papers delivered at a conference on health physics in nuclear installations, held at Risø, near Copenhagen, in May 1959, under the auspices of the Organization for European Economic Co-operation and the Danish Atomic Energy Commission. The purpose of the conference was partly to introduce the subject to those entering this field, and partly to permit the presentation and discussion of new results. Accordingly there are several introductory papers on such subjects as the biological effects of ionizing radiations, the basis of the maximum permissible levels of exposure, and measuring techniques.

These are followed by papers on the control of radiation-levels and of the contamination of personnel. Practical problems of health physics and criticality control in specific types of installation, including reactors, chemical plant, and high-energy accelerators, are discussed. There is a final section on emergency situations.

All the papers are by acknowledged experts from the United States, Great Britain and Europe, and are authoritative and well produced. This is a valuable record for those who attended the conference. However, for those new to the subject, it does not quite take the place of a well-organized text-book, and, since practically all the information it contains can be found in the technical literature, it is of limited use to experts. The volume will probably be a useful addition to many libraries.

W. J. Whitehouse

Absorption Spectra in the Ultraviolet and Visible Region

Edited by Dr. L. Lang, in collaboration with Dr. J. Szöke, Dr. G. Varsányi and M. Vizesy. Vol. 1: Pp. 414. Vol. 2: A Theoretical and Technical Introduction. Pp. 80. (Budapest: Publishing House of the Hungarian Academy of Sciences; London: Collet's Holdings, Ltd., 1959.) 137*s.* 6*d.*

These are the first two volumes of a series in which "subsequent volumes will contain spectra of foreign authors and the collection will thus emerge from its strictly national environment and assume an international character". Volume 1 includes the spectra of some two hundred assorted substances, mostly in solution, in the form of graphs of log ε against wave-length supplemented with tables of selected values of log I/I_0 at different wave-lengths for specified concentrations. The volume contains separate substance and formula indexes, but no attempt has been made at classification. It is impossible briefly to indicate the nature of the substances considered—which range from complex compounds of cobalt through substituted benzenes to phenanthrenes, flavones and xanthins. These are presented in loose-leaf: unhappily, the file containing the sheets of the review copy was not strong enough for its job.

Volume 2 consists of a "theoretical and technical" introduction. The text is some forty pages long. It will scarcely help those who know some spectroscopy already, and it is, naturally, too condensed to be of much value as an introduction. It is written in English which is nearly always intelligible but often odd. The discussion of the emission from a hydrogen lamp is not only odd but also incorrect.

The preparation of a reference set of ultra-violet spectra presents an enormous task, in which the first step is to adopt a practical classification. It is indeed useful to have the Hungarian results collected together, but this random sample seems unlikely to serve as a basis for the ultimate catalogue of these spectra.

R. F. Barrow

An Introduction to Industrial Mycology

By George Smith. Fifth edition. Pp. xvi+399. (London: Edward Arnold (Publishers), Ltd., 1960.) 40*s.* net.

The publication in 1938 of *An Introduction to Industrial Mycology* by Mr. George Smith was a marked contribution to the study of moulds. That the book has now reached its fifth edition is evidence of how well it has been received. The text of the fifth edition includes descriptions of a few genera and species of fungi which were not previously included, and the relevant literature of systematic mycology which has appeared since the publication of the fourth edition in 1954 has been considered.

The major portion of the book is devoted to descriptions and illustrations of most genera of moulds which regularly occur on industrial products. This section is of considerable value to students of general mycology especially because of the attention devoted to members of the Fungi Imperfecti and particularly to species of *Penicillium* and *Aspergillus*. The remainder of the book provides a most useful introduction to beginners in mycology, since it deals with laboratory equipment and techniques including microscopy and photomicrography. Mr. Smith is to be congratulated on presenting the subject-matter in a most readable form with complicated terminology reduced to a minimum. One of the delightful features of the text is the manner in which the author draws on his rich store of experience and gives practical advice on techniques and staining which is invaluable to newcomers in the field.

Almost all the illustrations are from original photomicrographs and, being of high quality, add greatly to the value of the book. As compared with the previous edition, one figure has now been omitted; but replacements of four plates and new illustrations of eight species are included. The publishers have maintained the high standard shown by the previous edition.

John Colhoun

NATURALLY OCCURRING ALPHA-ACTIVITY OF DRINKING WATERS

By R. C. TURNER, J. M. RADLEY and PROF. W. V. MAYNEORD
Physics Department, Institute of Cancer Research : Royal Cancer Hospital, London, S.W.3

THE present article represents a continuation of investigations into the nature and levels of naturally occurring α-activity in man and his environment. We have demonstrated the great variations of α-activity to be found as between different human foods[1]. Following the observations on foods it was natural to study the radioactivity of drinking waters supplied to the population of Great Britain.

Several investigators[2-8] have reported measurements of the radium-226 content of potable waters in other countries, but very few data have been published during recent years on the activity of waters in Britain. Following the observations of J. J. Thomson[9] early in this century on Cambridge water, there was considerable interest in this subject, but much of the earlier work leaves doubt as to whether the observed values applied to radium-226 or also included gaseous products such as radon-222, known to exist in certain waters at considerably higher levels of activity than its parent. In the present experiments we have measured the radium-226 content of 71 drinking waters available in Britain, and in addition we report the values for radon-222 and radium-224 (thorium *X*) when present.

In most instances the water samples have been made available to us by the co-operation of the local water undertakings at the request of the Ministry of Housing and Local Government

Experimental Procedure

The water samples were selected from several points of view, including the size of population supplied and the nature of the associated geological formations. The specimens were chosen with the view of assessing the total daily intake of natural radioactivity throughout Britain from its water supplies.

Preliminary experiments indicated that, if polythene containers were used for the collection and transport of the samples, it was unnecessary to add either carrier or acid agent to the water at the time of sampling. No residual α-activity could be detected on the walls of such containers even after they had housed specimens of relatively high activity for several days.

A litre of each specimen of water to be measured was evaporated to dryness in a 'Vitreosil' beaker and the α-activity of the residue measured, using the α-ray counting technique previously described[10]. In a few cases where the mineral content of the water was very low, 20 mgm. of barium chloride having known low α-activity was added to the water before evaporation in order to provide adequate residue.

Measurements were made on each specimen of residue immediately after evaporation and at intervals of a few days during the following 30 days, by which time the radon-222 and its α-emitting daughters polonium-218 (radium *A*) and polonium-214 (radium *C'*) would have reached equilibrium with the radium-226 present. After 30 days no further change of α-activity of the residue could be detected in any of the specimens. Assessment of the amount of radon-222 above the level required for equilibrium with the radium-226 present in each water was effected by observations on a liquid sample 2–3 mm. deep, sealed in contact with a zinc–cadmium sulphide phosphor of area 93 cm.[2]. Adsorption by zinc sulphide crystals of the daughter products of radon-222 present in solution had been previously reported by Rosholt[11], who used the method to obtain quantitative yields of lead-218 (radium *B*) and polonium-214 (radium *C'*).

It has been observed by us that, when water containing dissolved radon at a level of activity many times higher than its content of radium-226 is assembled in such an arrangement, the α-counting-rate increases for the first hour after sealing the sample and thereafter decreases with the half-life of radon-222 (3·8 days), until the activity has fallen to the level represented by the content of radium-226 and other long-lived activity. If at any intermediate stage the water is removed and the activity of the phosphor itself observed, the counting-rate decreases rapidly during the first 10 min. or so, corresponding to decay of polonium-218 (radium *A*), and thereafter falls with a half-life of approximately 40 min. compatible with the decay of lead-214 (radium *B*) and bismuth-214 (radium *C*). It is thought that the solid decay products of the dissolved radon are deposited on the surface of the zinc sulphide crystals and the α-particles emitted by polonium-218 (radium *A*) and polonium-214 (radium *C'*) are assumed counted with 2π efficiency. So long as the water itself is present, the observed activity is maintained with the half-life characteristic of radon, although the radon α-particles themselves may contribute little to the counting-rate since their range in the medium is only 1 or 2 per cent of the depth of the water layer.

Fig. 1 shows the characteristic pattern of decay of α-activity observed in a water sample containing radon greatly in excess of the amount required for equilibrium with its radium-226 content. Each estimate of radon content has been corrected for decay between the time of collection of the sample and the actual measurement.

In a number of the more active water residues, fast pairs of α-particles were observed, indicating the presence of at least the shorter-lived members of the thorium series[10]. This conclusion was borne out by the subsequent variation of the thorium series activity with time, since it decreased rapidly during the first 20 days or so following evaporation, after which the thorium activity remained constant at a relatively low level. The presence of radium-224 (thorium *X*) in American potable waters has already been reported by Stehney[2], who found the levels of radium-224 in freshly sampled waters comparable with those observed for radium-226. Due to the short half-life of radium-224 (3·64 days) and of its α-emitting daughter members of the thorium series, this α-activity decreases to very low values in the 2–3 weeks subsequent to sampling. There is little doubt that the decreasing thorium series activity observed

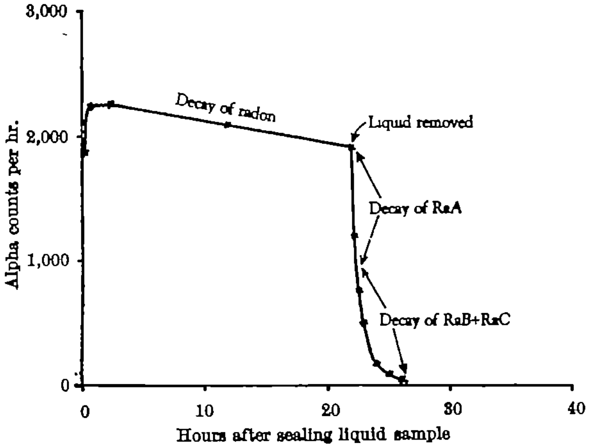

Fig. 1

in a number of our specimens is due to the presence of radium-224 and its daughters in the freshly sampled waters. In the absence of long-lived members of the thorium series, such as thorium-228 (radiothorium-228), at comparable levels of activity, the initial thorium series activity of these waters is regarded as due to radium-224 and its daughters. These values are given in Table 3 corrected for decay of activity since time of sampling.

In a number of the waters having very low activity it has not been possible to determine either the level of radium-224 or of the long-lived members of the thorium series.

In a few specimens having intermediate values of long-lived α-activity, the presence of thorium-228 and its daughters has been observed but at levels representing small fractions of the total long-lived α-activities given in Table 1.

Results

The values of long-lived α-activity together with the activities due to excess radon-222 and its daughters are given in Table 1 for various categories of water.

In a number of instances waters from more than one source have been measured for a given town, and these are listed separately. Ground-waters have been divided into two groups comprising those derived from boreholes in chalk and those from boreholes in other geological strata. Surface waters include sources such as springs, rivers, lakes and reservoirs.

Column 4 of Table 1 gives the content of solid matter observed (in parts per million), and column 5 the long-lived α-activity of this residue 30 days after evaporation of the liquid specimen.

Table 2 indicates the range of values and mean long-lived α-activity for the different categories of water and their residues.

In Table 3 the total α-activity of a number of the more active samples is broken down into its three main components.

Discussion

It will be seen from Tables 1 and 2 that the highest values of long-lived α-activity are found in the group of spa waters, which possess high contents of mineral matter having specific activities greater than those

Table 1

Origin	Long-lived α-activity (μμc./litre at 30 days)	Excess radon and daughters (μμc./litre at time of sampling)	Solid matter observed (parts per million)	α-Activity of residue (μμc./gm. at 30 days)

found for surface waters or waters derived from boreholes.

The Cornish specimens, although having a mean level of activity lower than the spa waters by a factor of 12, are still approximately ten times higher in activity than the mean values of chalk borehole or surface waters. The mineral contents of the Cornish waters are relatively low; but the mineral matter has specific activities ranging up to 92 μμc./gm., doubtless associated with the known deposits of uranium and radium in parts of that county.

Next in descending order of long-lived α-activity come the drinking waters derived from boreholes in geological strata other than chalk. The mean activity of this group is only slightly lower than that found for the Cornish waters, and this would appear to be due to their higher mean contents of mineral matter, 400 parts per million compared with 90 for the Cornish samples.

Waters derived from boreholes in chalk have still lower activities with a mean level down by a factor of 4 below those derived from boreholes in other strata. It is interesting to note that the mean value found for the α-activities of their mineral residues (1·5 μμc./gm.) is very close to that reported previously by us[12] for the α-activity of chalk specimens.

The least-active group of waters observed by us are surface waters from rivers, lakes and reservoirs, even though a number are derived from areas of Pre-Cambrian or granitic rock formations. Their mean mineral content is 100 parts per million and their mean long-lived α-activity is lower by a factor of 12 than the Cornish waters.

There was, of course, the possibility that a substantial fraction of the observed long-lived α-activity was due to uranium-238. However, measurements of uranium contents of a number of waters in Great Britain have been reported by Smith and Chandler[13], who found values of less than 1 μgm. (0·34 μμc.) per litre in 124 out of a total of 162 specimens examined. Waters with values higher than this figure were, with one exception, not drinking waters. Our own observations on the growth of α-activity of the residues during the 30 days following evaporation leave little doubt that also in our series of waters the content of radium-226 is several times higher than the activity due to uranium-238.

Moreover, investigations of the uranium contents of North American river waters by Rona and Urry[14] show a ratio of radium-226 to uranium-238 of approximately 4 : 1. In another study of the activities of ground waters in the United States, Scott and Barker[15] also observed levels of radium-226 in excess of those due to uranium-238.

These results are borne out by the chemical estimations made by us of the uranium-238 contents of a number of our more active residues. These confirm the presence of uranium at levels of activity which represent only a small fraction of the total long-lived α-activity in each case. It is to be noted that even if the radium/uranium ratio is as low as 4 : 1, then the α-activity due to radium-226 and its daughters will still comprise 90 per cent of the total long-lived activity contributed by members of the uranium series.

In respect of the thorium series, Stehney[9] found no evidence of long-lived members such as thorium-228 in his studies of American potable waters, while Rona and Urry[14] assessed the ratio of thorium-230 (ionium-230) to uranium-238 in North American river waters as being a very small fraction of unity. The very low levels of long-lived α-activity due to the thorium series found by us in the present investigation agree with the findings of these observers.

In the absence, therefore, of either uranium-238 or thorium-228 at levels of activity comparable with those due to radium-226, the long-lived α-activities listed in Table 1 may be regarded as due to radium-226 and its α-emitting daughters, radon-222, polonium-218 and polonium-214, existing in radioactive equilibrium. The radium-226 content of any particular specimen is therefore taken as one quarter of the long-lived activity given in column 2 of Table 1. It will be seen, therefore, that the contents of radium-226 observed in this series of waters cover a range of 2,400–1, namely, from 0·005 μμc./litre to 12·1 μμc./litre.

If we exclude the spa waters and assume a daily intake of 2·5 litres per head of the population of Britain[16], then the daily intakes of radium-226 from water alone cover a range of almost 500–1, namely, from 0·013 μμc. to 5·9 μμc. In terms of long-lived α-activity the intakes from water range from 0·05 to approximately 24 μμc. per head per day.

So far we have considered only the long-lived α-activity due to the presence of radium-226 and its daughters. It will, however, be seen from Table 1 that a number of the waters possess relatively very high contents of radon-222 and its daughters at the time of sampling. This is especially the case in the Cornish specimens where the α-activities due to radon-222 and its daughters, polonium-218 and polonium-214, range up to 10,000 μμc./litre. On the basis of a daily intake of 2·5 litres the ingested α-activity can therefore be as high as 25,000 μμc. a day, that is, approximately 8,000 μμc. of radon and of each of its two short-lived α-emitting daughters. In any attempt to assess the possible significance of these materials we are faced with an almost complete lack of data concerning their metabolism in the human body. Meyer[17] in a classical series of experiments in the late 1920's came to the conclusion that radon ingested in drinking water had a 'mean life' of about 1 hr. in the body, being excreted principally by the lungs. On this assumption it is easy to calculate that during its stay in the body approximately 0·75 per cent, that is, 60 μμc. of radon and of each of its two α-emitting daughters, disintegrate completely. Since 1 μμc. of radon-222 comprises 1·78 × 10^4 atoms of radon, this implies the production of about 3 million α-particles and of a million or so atoms of lead-210 (radium *D*) in the body as the result of each day's intake of such water. In a future paper it is hoped to discuss certain aspects of the radiation dosimetry resulting from these findings.

It will be seen from Table 3 that a number of waters at the time of sampling also contain radium-224 (thorium *X*) and its three α-emitting daughters at levels of activity comparable with those of the long-lived activity due to radium-226 and its daughters. Since radium-224 is an isotope of radium-226 their fundamental chemistry would be identical, but the short mean life of radium-224 and its decay products may result in a very different distribution of absorbed energy.

Daily Intakes of Alpha-Activity

We now consider the mean daily intakes of α-activity per head of population resulting from drinking water. From information kindly supplied by the Ministry of Housing and Local Government we have estimated the number of consumers of each of the principal water supplies. Assuming a daily intake of 2·5 litres per head the mean daily intakes of α-activity from this source for various sections of the population are estimated in Table 4.

Table 4. MEAN DAILY INTAKE OF α-ACTIVITY FROM DRINKING WATER μμc. PER HEAD OF POPULATION

Group of population	Long-lived activity Ra-226 and daughters +	Activity radon and daughters	+ Activity Ra-224 and daughters
Cornwall	4·5	8,300	~ 5·5
London area	1·0	20	very small
Whole of Britain	0·5	17	,, ,,
Scotland	0·25	2	,, ,,
Spa patients (1 litre per day)	21·1	~ 1,000	—

It will be seen that the mean daily intakes of long-lived α-activity for the four groups cover a range of 18 to 1, whereas from Table 1 it is clear that the range of individual intakes may exceed 400 to 1. For the mean daily intakes of radon plus daughters we have a range of 4,000 to 1 between the groups, with the range for individuals exceeding 10,000 to 1. The low mean value of long-lived α-activity in the Scottish waters illustrates, rather surprisingly, the low values which may be encountered in areas of granitic formations. For comparison, Table 4 also shows the approximate daily intake of α-activity resulting from the consumption of 1 litre per day of British spa water having an activity equal to the mean value observed by us for this type of water.

Maximum Permissible Levels of Natural Activity

The report of the International Commission on Radiological Protection[18] deliberately excludes 'natural background' from its scope. It is, however, recommended by the International Commission that, in considering the exposure of large populations in relation to somatic effects, the maximum permissible level be taken as one thirtieth of the continuous occupational value (168 hr./week) computed according to its basic rules. The value of maximum permissible concentration for soluble radium-226 in water suggested by the International Commission for continuous occupational exposure is 100 μμc./litre, so that the value for large populations would be 3·3 μμc./litre. This value is lower than our observed values for British spa waters and two Cornish waters. The activities of several other waters are more than 10 per cent of this estimate. A similar situation has been noted for some large populations in the United States[19].

However, direct observations by us[10] on human skeletons from Cornwall show that the radioactivity observed in them is many times less than would be expected on the basis of the assumptions made by the International Commission. The observed mean level of activity of the skeletons is a factor of at least a thousand below the lowest body burden known to have resulted in a tumour.

The apparent anomaly arises largely because the biological parameters which have been used in the calculations were based on observations on human subjects having large radium burdens acquired many years previously and who were therefore excreting the radioactive material at a very low rate.

In a previous article[20] we reported investigations of the levels of natural α-activity present in the daily diets of the population of Great Britain and came to the conclusion that the daily intakes of such activity could vary from a minimum of 4 or 5 μμc. to 400 or 500 μμc. or even more, depending on the particular choice of diet. It is evident that in places where the drinking water has a level of α-activity at the higher end of our observed range and the individual intake from food happens to be at the lower end of the range of dietary activity, then the daily intake of natural α-activity will be dominated by the contribution from water. In other locations where the drinking water is derived from surface sources having much lower activity, the contribution from food will be predominant, regardless of the choice of diet.

Whether the human body finds it easier to retain radium-226 and its daughters present in soluble form in drinking water than to retain the same elements, possibly in different chemical form, ingested in food, is not yet known. The relative contributions made by water and food to the real retention and utilization by the body of α-active substances and the factors which control retention in the two cases are the subject of present investigations.

Comparison with Fission Product Activity in Waters

Finally, perhaps we may consider these daily intakes of natural α-activity in water in relation to the published figures of the artificial β- and γ-activity due to the presence of strontium-90 and cæsium-137 in drinking water in Great Britain[21].

The pattern of distribution of these fission products is quite different from that of the natural α-activity, since they appear at their highest levels in surface waters. Ground waters have extremely low contents of fission products, but, as we have seen, high values of natural α-activity.

From the latest figures available (for the first half of 1959) we calculate the mean contents of strontium-90 and cæsium-137 in surface waters as 0·75 $\mu\mu$c./litre and 0·20 $\mu\mu$c./litre, respectively. The mean daily intakes of populations ingesting such drinking waters would therefore be 1·9 $\mu\mu$c. and 0·5 $\mu\mu$c. of the two nuclides, respectively.

For large populations the International Commission on Radiological Protection suggests 33 $\mu\mu$c./litre and 6,000 $\mu\mu$c./litre in water, respectively, for these materials as the maximum permissible concentrations. It will be seen that the observed values are very small in comparison to these permissible levels.

Note added in proof. Since these investigations were completed, we have had the opportunity of examining specimens of drinking waters supplied to Horrabridge, Devon. The radioactivity of these particular waters has been the subject of recent communications[22,23] concerning the incidence of cancer in the area. We find the long-lived natural activity of the Sampford Spiney supply to be 0·6 $\mu\mu$c./litre, and its content of radon + daughters 2,500–5,000 $\mu\mu$c./litre. It will be seen that these values are well within the range reported in Table 1 above for waters in south-west England.

Many of the water samples were obtained through the goodwill and co-operation of Mr. A. W. Kenny, of the Ministry of Housing and Local Government, who kindly approached on our behalf the chief engineers of numerous water undertakings, to all of whom we would like to express our sincere thanks.

Our thanks are also due to Mr. J. Crookall, of this Department, for chemical estimations carried out on a number of the samples.

FIRE RESEARCH*

By S. H. CLARKE, C.B.E.

THE continuous systematic study of fire protection started in Europe and the United States in the closing years of the last century. Added impetus came with the Second World War, and modern fire research owes much to the vision of the late Sir Reginald Stradling, chief scientific adviser to the Ministry of Home Security, to Lord Falmouth, head of the Fire Research Division, and to the knowledge and experience of Prof. G. I. Finch and Dr. D. T. A. Townend. Prof. Finch suggested critical experiments which were of great value in elucidating some of the more important phenomena. He showed that, although many of the problems of fire protection were extremely intricate, they were in fact the result of a pattern built on relatively simple principles.

For a fire to occur there must be fuel, oxygen, and a source of ignition; there are exceptions, but they are of almost negligible practical importance.

It is helpful to approach the study of fire by examining a shallow dish of petrol—a volatile, flammable liquid. If a small flame is gradually brought near the surface the vapour ignites when the flame is perhaps an inch from the liquid; the eye can just follow the rapid spread of flame. Incidentally, a cigarette can be extinguished by gently dipping the lighted end into a tray of petrol.

If the experiment is repeated with a tray of a less volatile liquid, say paraffin (kerosene), it will be found that quite a large flame must be played directly on the surface for a short time before ignition takes place. Once ignition occurs, however, and the liquid is warm, if the flames are snuffed out by placing a board over the tray, immediate re-ignition occurs when a fresh flame approaches the surface, exactly as with petrol.

It is thus necessary to distinguish two temperatures; first, the 'flash-point', which is the temperature at which vapour distils rapidly enough to support a flame; and, secondly, the 'ignition temperature'—and this is usually a higher one—at which the flammable vapours can be ignited.

Although the chemical processes that are involved when wood is burned are much more complicated, in some ways wood and other similar materials may be thought of as behaving like liquids with a high flash-point. When wood is heated, it decomposes, and gases and vapours are formed which, in contact with air, behave just like those of petrol or paraffin, and burn with flame.

G. I. Finch summarized very neatly the behaviour of wood as a fuel. He found it convenient to classify combustible materials in three grades which he called "tinder", "kindling" and "bulk fuel". Tinder can be ignited by an ordinary match and is then able to continue burning; it has a specific surface of not less than 20 cm.^{2}/gm.; paper or wood shavings are an example. Kindling cannot be ignited by a match but can by tinder, and, if it is suitably arranged, can continue to burn; it has a specific surface of not less than 2 cm.^{2}/gm. Bulk fuel can only be ignited by a

---

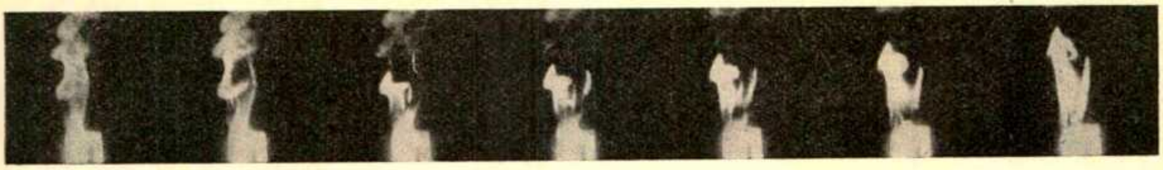

Fig. 1. Successive stages in the ignition of wood by radiation. Pictures taken at about 0·01 sec. exposure. Note ignition occurs above the specimen outside the radiation field. By courtesy of the Director of the Fire Research Station. Crown copyright reserved

fire which already involves kindling, but under suitable conditions it can sustain self-combustion; its specific surface is less than 2 cm.^{2}/gm.

P. H. Thomas and D. L. Simms observed an interesting feature in the burning of wood. When small specimens are subjected to radiant heat of high intensity, vapours and gases are emitted which ignite spontaneously. The interesting thing is that ignition occurs not at the point of applied heat but some distance above, and the flame jumps back rapidly to the wood (Fig. 1).

It should be noted that it is inaccurate to speak of a liquid burning; combustion occurs in the vapour phase, and in a region where there are convenient proportions of vapour and oxygen. When wood burns, about half the mass is consumed as flame and about half glows as charcoal.

The processes described form the background to the early stages of most fires. Once started, a fire spreads until all the exposed surface of combustible material is involved in flame. At that moment the maximum temperature is reached. The rate at which it is reached depends largely on the amount and arrangement of the combustible materials. When it is reached, subsequent developments depend largely on the access of air to the fire.

There are two basic principles of practical fire protection, namely, the control of possible sources of ignition, and the control of the amount of combustible material that can be involved at one time. The latter frequently involves the division of large buildings into compartments each of which has a pre-determined degree of fire resistance.

Observations of the temperatures reached at many large fires, and in experiments, have led to the almost universal acceptance of a standard time-temperature curve which is considered to represent the conditions in a severe fire. 'Fire resistance' is defined as the length of time for which a unit of structure continues to perform its design function when it is heated in a furnace which is controlled according to the standard curve. By-laws in most countries now require buildings in towns to be constructed so that their walls, floors, structural columns, and certain doors and windows reach an appropriate degree of fire-resistance. Steel columns have a fire resistance of about ten minutes, and the problem is, therefore, to provide them with a heat-resisting coating which will stay in position when involved in fire.

It sometimes comes as a surprise to find that steel behaves so badly in fire; but it may be a greater one to learn that a number of fires have been caused by the combustion of fine steel-wool, which is readily ignited by a match, or even by allowing a handful to fall across the terminals of a small battery; and there have been many fires in boilers in which overheated steel tubes have burned in high-pressure steam.

The variety of possibilities in constructing fire-resistant buildings is so great, and the present state of our knowledge so small, that full-scale tests are often necessary before approval can be given for the use of a new form of building construction. Furnaces were built by the Fire Offices Committee nearly thirty years ago to enable such tests to be carried out, and they were immediately made available to the Building Research Station of the Department of Scientific and Industrial Research for research purposes. When the Joint Fire Research Organization was set up in 1947, they formed part of the contribution of the Fire Offices Committee to this Organization.

Fig. 2 shows a specimen after test, and gives an idea of the size of the operation. Such tests are costly and time-consuming, and much research has been designed to find means of eliminating them, or at least of conducting them on a smaller scale. The work has involved the search for mathematical expressions for the variations in temperature in every part of a wall, floor, column, etc., when the temperature at the surface is raised at the rate demanded by the standard time-temperature curve. The construction of these may be elaborate, and even when the thermal constants of the constituents are known the calculation of rise of temperature in the steel is a difficult

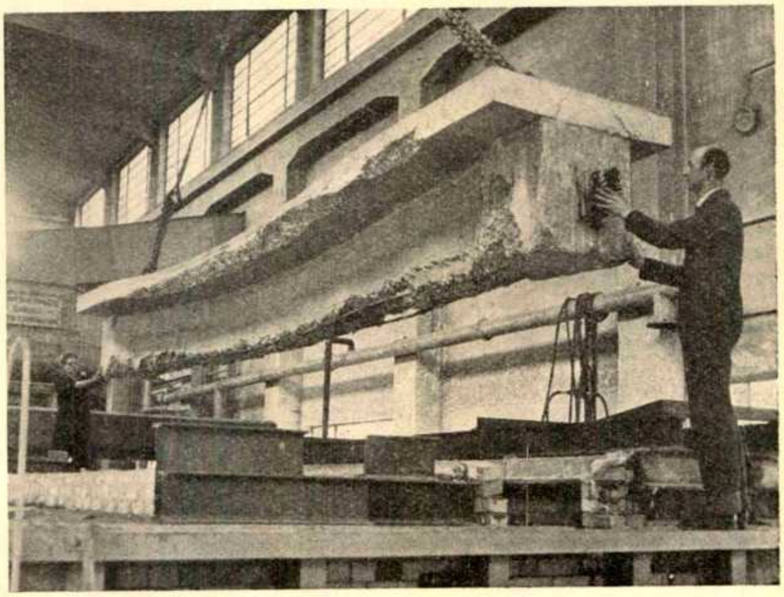

Fig. 2. Full-size specimen of pre-stressed concrete beam after fire resistance test. By courtesy of the Director of the Fire Research Station. Crown copyright reserved

and tedious operation. Lawson and McGuire devised and constructed an electrical analogue which has proved extremely valuable both as a research tool and in reducing the number of full-scale tests. It exploits the close analogy which exists between the flow of heat in solids and the flow of a charge along a transmission line composed of series resistance and shunt capacitance elements.

The analogue deals with one scientific problem, namely, the behaviour of units of building construction under closely defined conditions. There remains a wide range of problems resulting from the movement of hot gases and the transfer of heat, such as the provision of escape facilities in high buildings, the control of smoke in large basements or in ships, the 'mushrooming' of hot gases in buildings of large area, the detection of fire, and many aspects of extinction. Before these can be studied on a small scale, there is need of a reliable technique for the use of models. Considerable progress in this direction has been made by P. H. Thomas and C. T. Webster. Working with similar cubical models, of 1–10 ft. side, they have studied the burning of wooden cribs of various sizes, and have established relationships that have already enabled them to deal with some practical situations.

It has long been recognized, for example, that, smoke is perhaps the fireman's greatest enemy. It offers particular difficulties in buildings with a large expanse of floor area with all kinds of obstructions which together make it impossible for the fireman to see or to find his way to the seat of the fire. The Covent Garden fire and several other recent large fires in Great Britain have focused attention sharply on this problem. They have led to a revived interest in a method of fire protection that has been employed in theatres for many years, namely, the provision of emergency venting in the roofs to release the smoke and hot gases at an early stage in the fire. P. H. Thomas has recently developed for the first time what appears to be a satisfactory solution with an adequate theoretical basis. Using models, he has explored the combined use of 'curtains' to restrict the lateral spread of smoke in conjunction with roof-vents of various sizes, and has established a relation between vent area and the proportion of heat released in experimental conditions.

Detection

Experience of large fires soon convinces that, when they get beyond a certain size, total destruction is inescapable. A surprisingly large proportion of the total damage is caused by a relatively small number of large fires; each year nearly half the damage in the United Kingdom is caused by some 200–300 out of some 50,000 fires in buildings attended by the fire brigades. Of the many factors that contribute to the development of large fires the most important is failure to detect and attack them while they are still small. P. Nash and R. Pickard have explored the rise in temperature and the movement of hot gases over fires of various sizes in enclosures of various heights and shapes, a task which called for entirely new instruments for measuring air-flow. Using the results of this work, together with information about the distance of travel of fire brigades and experience of the desirable balance between high sensitivity and the likelihood of false alarms, they have succeeded in developing a standard procedure which enables the merits of new designs of detector to be assessed.

Before leaving the subject of the occurrence of fires, reference should be made to the fact that effective statistics are collected with the collaboration of the fire brigades of the local authorities, by arrangement with the Home Office. These have yielded a number of interesting results, including indications of significant differences in behaviour of pre-war and post-war houses and 'pre-fabs'—the post-war housing having the best record. They have revealed a steady increase in fires associated with electrical equipment, and with the use of certain types of oil-burning apparatus.

Extinction

When attempts to control sources of ignition and accumulations of fuel have failed, there remains the task of fire extinction. The most common method is to cool the fuel to a temperature at which the flammable vapours cease to be emitted.

The commonest extinguishing agent is water, and the principles that govern its use have not changed fundamentally over hundreds of years. Whenever it can be used, it is incomparably the best medium. There is plenty of it and it is cheap; it is easily transported (by pipes) and easily applied; it has a large thermal capacity and it boils at a convenient temperature, absorbing a useful amount of heat in doing so. The only circumstances in which plain water is not the best medium are electrical fires, fires involving flammable liquids the flash-point of which is below atmospheric temperatures, and circumstances in which water damage must be avoided at all cost.

The main lines of research in recent years have aimed at improvements in methods of applying water. Since the War improvements in equipment, training, and technique have resulted in a marked and continued steady improvement in the effectiveness of fire brigades in the United Kingdom.

In the early post-war years the opinion was held in some quarters that high-pressure sprays, which were believed to have very fine drops, represented the ultimate in efficiency. A long and careful study by D. Hird, in which the fire brigades in London and Birmingham took part, demonstrated that there is no material advantage in increasing operational pressure much above about 100 lb. per sq. in., and any theoretical merit fine drops may have in extinction is offset by their limited trajectory.

D. J. Rasbash has shown that, where water is used, fires in liquids which cannot be cooled below their flash-point can be extinguished in the vapour phase by the use of a very fine spray. Less-volatile liquids such as fuel oil can be extinguished by cooling, and larger drops which will pass through the flames and reach the surface of the liquid are more effective.

Another way of using water is as foam, which is made by dissolving a foaming agent (often a protein derivative) in water and aerating the solution mechanically, or by producing bubbles of carbon dioxide chemically. The function of the foam is to cover the surface of the liquid and to shield it against radiant heat from the fire, thus cutting off the supply of flammable vapour.

During the War it was found possible to introduce foam at the base of a tank of fuel oil, and to let it rise by its low relative density and spread over the surface of the oil. This was not possible with petrol, because in ascending through the bulk of the liquid the foam became impregnated with petrol, which continued to burn and destroyed the foam. Recent work has led

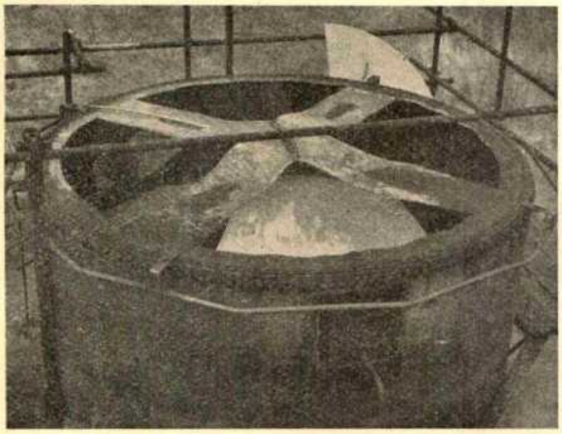

Fig. 3. Last stages of extinction in petrol fire by foam injected at the base of a tank 30 ft. high. By courtesy of the Director of the Fire Research Station. Crown copyright reserved

to the surprising conclusion that very sloppy foams, with an expansion of about three times, are effective even with petrol (Fig. 3).

Two other types of extinguishing agents are used for special fires. The first are known as vaporizing liquids, the commonest being carbon tetrachloride. They operate in the vapour phase by absorbing heat, and possibly also by inhibiting combustion. Research has been devoted to seeking to understand the reactions involved, and to seeking the most effective of a wide range of reagents. Taking into account cost, convenience, toxicity of the agent or its decomposition products, chlorobromomethane has come to be regarded as the best of the available materials.

D. J. Rasbash recently made the bold suggestion that the principle of controlling the atmosphere might be used on the grand scale even for such fires as that at Covent Garden. A large jet-engine was specially modified by the National Gas Turbine Establishment, and the exhaust gases from this engine are being used experimentally in a large building to see how far practical use can be made of the principle. The inert, exhaust gases do not cool the fuel, but it is hoped that they will prevent the spread of combustion long enough for a fireman to be able to approach with his hose.

The other type of medium is known as 'dry-powder', the commonest form being sodium bicarbonate. Research has not yet fully elucidated its mode of action, but experience has thrown considerable doubt on its superiority over other cheaper and better-known methods.

Fire as a Social Problem

Fire is a social problem. An example will illustrate the complications that are encountered in applying the results of research. A few years ago D. I. Lawson and his colleagues studied the occurrence of casualties through the ignition of clothing. Fire brigades and a number of hospitals co-operated by sending reports on a large number of incidents, and when possible they sent samples of the fabrics which were first ignited. The researches involved studies of a large range of fabrics in the laboratory, and a simple equipment was developed as a standard measure of their flammability. Statistics showed that nearly a quarter of the fatal casualties were children, and of those a large proportion were wearing nightdresses. Very few occurred between the ages of about 10 and 60, and the vast majority were elderly people and often old ladies. It became clear that the practical solution was not to aim immediately at the prohibition of all but flame-resistant fabrics ; there was need for special care of the young and old, who might wear such materials, and increased attention to the control of sources of ignition such as electric fires, gas fires, and the domestic fire. It was considered important that the public should be informed about the special hazards of certain fabrics and that means should be provided for them to be able to recognize the ones which presented the least hazard.

Fire touches practically every aspect of life, and deliberations of this kind call for wide collaboration. Some fourteen Government Departments in Britain have special concern in fire protection : the Home Office is responsible for the safety of the public where they assemble in buildings and other places, and for ensuring that the efficiency of the fire brigades is maintained : the Ministry of Transport for safety in ships : the Ministry of Aviation for aircraft, and so on. The Fire Research Board gives opportunity for members of industry and of the universities to consider their problems and, with assessors from the Government departments, to ensure that the research programme is balanced and co-ordinated.

The Joint Fire Research Organization itself is believed to be the only example of complete and equal partnership of Government (through the Department of Scientific and Industrial Research) and industry (through the Fire Offices Committee) in arranging at national level for research to deal with a social problem.

OBITUARIES

Prof. Erwin Schrödinger, For.Mem.R.S.

Erwin Schrödinger, who died on January 4, was a man with outstanding ability to apply abstract mathematical reasoning to the advancement of physical theory. His great discovery, namely, Schrödinger's wave equation, as the basis of the description of atomic processes, was one of the most surprising of all the sudden advances that have occurred with the development of scientific knowledge.

Schrödinger was born in Vienna in 1887. He was a student at the University of Vienna during 1906–10, and then acquired a mastery of eigenvalue problems in the physics of continuous media, so laying the foundation for his great work. He became assistant at the University of Vienna, and later served as an artillery officer during the First World War.

In 1920, having married Annemarie Bertel, he went to Jena to take up an academic position. This was followed by positions at Stuttgart (extraordinary professor), Breslau (ordinary professor), and then the University of Zurich, where he settled for six years. Throughout this period he was very actively engaged in research in theoretical physics and published many papers, mostly on the specific heats of solids and other questions of thermodynamics, and on atomic spectra.

He has told me how he came to make his great discovery. With his work on spectra he was using, of course, Bohr's orbit theory, but he always felt that the quantum conditions in this theory were unsatisfactory and that atomic spectra should really be determined by some kind of eigenvalue problem. In 1924, de Broglie published his work on waves associated with the motion of free particles. This influenced Schrödinger profoundly, and he set to work to try to generalize de Broglie waves to bound particles. He finally obtained a neat solution of the problem, leading to the appearance of the energy-levels as eigenvalues of a certain operator. He immediately applied his method to the electron in the hydrogen atom, duly taking into account relativistic mechanics for the motion of the electron, as de Broglie had done. The results were not in agreement with observation. We know now that Schrödinger's method was quite correct, and the discrepancy was due solely to his not having taken the spin of the electron into account. However, electron spin was unknown at that time, and Schrödinger was very disappointed and concluded that his method was no good and abandoned it. Only after some months did he return to it, and then noticed that if he treated the electron non-relativistically his method gave results in agreement with observation in non-relativistic approximation. He wrote up this work and published it in 1926, and in this delayed manner Schrödinger's wave equation was presented to the world.

A short time previously Heisenberg had discovered his matrix mechanics, another formalism for dealing with atomic processes. The theories of Heisenberg and Schrödinger were soon found to be equivalent, there being a mathematical transformation that converts one into the other. Two independent and apparently entirely different lines of thought thus led to the same foundation for atomic physics.

Schrödinger published a series of papers in quick succession, developing his ideas. For this work he shared the Nobel Prize in Physics for 1933.

In 1927 he unfortunately moved to Berlin, where he became Planck's successor. In consequence his life became disturbed by political developments, and with Hitler's coming to power in 1933, he decided he could not continue in Germany. He came to England, and for a while held a fellowship at Oxford. In 1936 he was offered a situation at Graz. He was well aware of the uncertain position of Austria at that time, and it was a difficult decision for him to make; but the attraction of returning to his native country outweighed his caution and he accepted.

With the German annexation of Austria in 1938 Schrödinger was immediately in difficulty, because his leaving Germany in 1933 was taken to be an unfriendly act. He was forced to express his approval of the Nazi regime, and he did this in as ambiguous a way as he could (see *Nature*, **141**, 929; 1938).

He soon found life with the Nazis intolerable, and, profiting by the fact that they had neglected to take away his passport in the first place, he was able to slip across the frontier to Italy. He proceeded to Princeton University and after a short stay there moved to Dublin, to the newly created Institute for Advanced Studies, where he became director and remained until his retirement in 1955.

All this time Schrödinger continued his research and published many papers on a variety of topics. Some of them were concerned with unifying gravitation and electromagnetism, the problem which absorbed Einstein for many years and which is still unsolved. Schrödinger remained greatly interested in the foundations of atomic physics. He did not like the generally accepted dual description in terms of waves and particles, with a statistical interpretation for the waves, and tried to set up a theory in terms of waves only. This led him into controversy with other leading physicists.

Schrödinger was unconventional in his way of life. When he went to the Solvay conferences in Brussels, he would walk from the station to the hotel where the delegates stayed, carrying all his luggage in a rucksack on his back and looking so like a tramp that it needed a great deal of argument at the reception desk before he could claim the room that had been reserved for him.

After his retirement he returned to an honoured position in Vienna. He died after a long illness. He is survived by his wife, who was his faithful companion throughout their marriage.

P. A. M. Dirac

Dr. Sidney Marsh

Dr. S. Marsh, who was head of the Physics Department of Battersea Polytechnic from 1919 until 1950, died on December 14, at the age of seventy-six.

After completing a double first in physics and mathematics at University College, Cardiff, he went to Munich and Göttingen, where he obtained his Ph.D. on work on discharge tubes under Prof. E. Riecke. He joined the staff of Battersea Polytechnic in 1909 and, except for the two years 1917–19, when he was head of the Mathematics and Physics Department at Rutherford Technical College, Newcastle on Tyne, he remained there until his death. He was appointed head of the Department in 1919, and, after his retirement in 1950, he continued as a part-time lecturer giving more than part-time service. He gave his last lecture on December 12, 1960, two days before his death. The way he continued to adapt himself to the rapidly changing conditions of work in the post-war period was very remarkable. Old regulations and new regulations, general and special degree, polytechnic and college of advanced technology, he took it all in his stride.

His research interests lay in electrolysis and gas discharges, but the passion of his life was teaching, and, while this goes unrecorded in the proceedings of learned journals, it lives on in the hearts and minds of all those that passed through his Department during his long stay there. With immense energy he also threw himself into the examination work of the University of London, and for many years right up to his death he was the mainstay of the external examinations in physics. Marsh must have been a name to countless students, the world over, who never knew of the immense pains he took to be fair to them and the compassion with which he carried out his duties as an examiner.

As a young man taking over what had been his Department for so long, I might have expected to find him a little difficult as a colleague. Far from this being so, he was a most kindly and considerate person who was never obtrusive with his advice, though always willing to give it. He had that true humility that is a token of true greatness, and those who have known him and have worked with him mourn his loss greatly.

L. R. B. Elton

Mr. H. T. Pledge, C.B.E.

By the death of Mr. H. T. Pledge on December 28, the library and scientific worlds have suffered a great loss.

Humphrey Thomas Pledge, son of Thomas Pledge, was born on November 6, 1903. He went to Tonbridge School and thence as an Exhibitioner to Trinity College, Cambridge, where he took a first in the Natural Sciences Tripos. After a short period of teaching at Wrekin College he entered the Science Museum Library as an assistant keeper in 1928.

During his early years in the Library, Pledge was concerned with its services to industry, both in lending and in providing information. It was during this time that he collected material for his major work, published by H.M. Stationery Office in 1939, under the title *Science since 1500*. This is a comprehensive and masterly historical survey of the development of the physical and biological sciences, which has been widely accepted as a standard book of reference. It has been reprinted three times in Great Britain and has also been published in the United States.

In 1945, Pledge became keeper of the Science Museum Library, and the full burden of the restoration of its services after their dislocation during the War fell on his shoulders. Later developments which added to his administrative responsibilities were the photocopying service and the impact on the Science Museum Library of the formation of the National Scientific Lending Library to take over gradually the former's lending service to industry. During his tenure of the keepership he continued to build up the Library into one of the finest scientific libraries in Britain, in spite of stringent limitations on the financial resources available to him.

Pledge's interests were wide, ranging from biography through the physical and biological sciences to ethnology and archæology, and his knowledge was deep. His book brought fellow workers on the history and philosophy of science from all over the world to South Kensington to visit him. He took an active part in the founding of the British Society for the History of Science.

In 1934, Pledge married Ruth, daughter of the Rev. H. M. Brown, and they had one daughter. He was made a C.B.E. in 1960.

S. E. JANSON

NEWS and VIEWS

U.S. Atomic Energy Commission: Dr. Glenn T. Seaborg

Dr. Glenn Theodore Seaborg, who has been appointed chairman of the U.S. Atomic Energy Commission, was born in Ishpeming, Michigan, on April 19, 1912. After graduating at the University of California in chemistry in 1934, Dr. Seaborg held various research and teaching appointments in that University until 1942, when he was appointed section chief in the Manhattan Engineer District's Metallurgical Laboratory at the University of Chicago, where he conducted research in nuclear chemistry and physics; here he was responsible for developing the process used for the separation of plutonium from fuel elements irradiated in the production reactors at the Hanford installation at Richland, Washington. In 1946 he returned to the University of California at Berkeley as a professor in the Department of Chemistry. He was appointed chancellor of the University in 1958.

While serving as instructor at the University of California in 1940, Dr. Seaborg was co-discoverer of element 94 (plutonium), the first of a number of trans-uranic elements which his research activities revealed over the next fifteen years. He was the discoverer in 1941 of the isotope used as a source of nuclear energy, plutonium 239; in 1942 of the uranium isotope, uranium 233; in 1944 of elements 95 (americium) and 96 (curium); co-discoverer in 1949 of element 97 (berkelium); co-discoverer in 1950 of element 98 (californium); in 1952 of element 99 (einsteinium); in 1953 of element 100 (fermium); and in 1955 of element 101 (mendelevium). He was a member of the Atomic Energy Commission's General Advisory Committee from 1946 until 1950; member of the Joint Commission of Radioactivity, International Council of Scientific Unions, since 1946; and of the Committee of Standards and Units of Radioactivity, National Research Council, since 1947.

Anatomy and Biology at Western Reserve University

Prof. Marcus Singer has been appointed Henry Willson Payne professor of anatomy in Western Reserve University, Cleveland, Ohio. He is at present professor of zoology and of child development and family relationships in Cornell University. Prof. Howard A. Schneiderman, associate professor of biology in Cornell University, has been appointed professor of biology in Western Reserve University. Both appointments will be effective July 1, 1961.

A native of Pittsburgh, Prof. Singer first graduated from the University of Pittsburgh, and later was awarded M.A. and Ph.D. degrees by Harvard University. He was on the Harvard staff during 1938–51, first in the Biology and Zoology Departments and later in the Anatomy Department of the Medical School. In 1950 he served as visiting professor at the Long Island College of Medicine in Brooklyn, New York. He went to Cornell as associate professor of zoology and of child development and family relationships in 1951 and became a full professor in 1953.

Prof. Schneiderman is a native of New York City. He attended Swarthmore College and Columbia University and graduated from the former in 1948 with honours in mathematics and natural sciences. He was granted the degree of M.A. and a doctorate by Harvard University. During 1952–53 he was a University research fellow in biology at Harvard. In 1953 he was appointed assistant professor of zoology at Cornell and was appointed associate professor in 1956.

Botany at Calcutta: Prof. S. M. Sircar

Dr. S. M. Sircar has recently been appointed Sir Rashbehari Ghosh professor of botany in the University of Calcutta. This chair, created in 1914 in the name of its donor, is the oldest in Indian universities for fostering research work in botany with special reference to agriculture. Dr. Sircar was educated at the Presidency College and the University College of Science, Calcutta. During 1934–36 he worked under Prof. F. G. Gregory, at the Imperial College of Science and Technology, London. After returning to India in 1937 he joined the University College of Science, Calcutta, and took active interest in organizing research in plant physiology, particularly with reference to the rice plant. During 1946–47 Dr. Sircar served as acting head of the Department of Biology in the University of Dacca and from 1949 until 1951 he was on deputation with the Government of India as professor of agricultural botany in the Central College of Agriculture, New Delhi. He has created a strong school of research in Calcutta with special reference to vernalization, photoperiodism, mineral nutrition, germination and auxin relations of the rice plant. In 1954 he was elected a Fellow of the National Institute of Sciences of India. In 1958 he was awarded a travel grant by the Rockefeller Foundation to visit various universities and research institutes in Europe, the United States and Japan. The appointment of Dr. Sircar to the chair is a fitting recognition of his long association with the University of Calcutta and his continued interest in the rice plant.

School of Management Studies, University of Bristol

The University of Bristol is to establish a School of Management Studies for the purpose of providing residential courses in management studies and for conducting research into problems of business management and administration. This has been made possible by an offer by the Foundation for Management Education to underwrite the sum of £14,500 a year for a period of seven years in support of the School, and by the agreement of the University Grants Committee to supplement the Foundation's support with a contribution of its own. The initial programme for the School will be the offer of a residential course for executives in the 28–34 age group, who have attained departmental responsibilities and who are nominated by their employers as being suitable for the kind of training which the School will provide. The course will be of eight weeks duration, divided into two periods of four weeks each, these periods being separated by an interval of about ten weeks, during which the students concerned will be expected to undertake specified studies within their own employing organization. It is intended that the session 1961–62 will be occupied as a preparatory year for the School and its first admissions should be in the autumn term of 1962. Further information can be obtained from the Registrar, University of Bristol, Bristol 8.

Scientific Literature on Fire

The tenth volume of *References to Scientific Literature on Fire* has recently been published by the Fire Offices' Committee, Joint Fire Research Organization (Library Bibliography No. 5/Part X. By Miss E. M. Shakeshaft and Mrs. B. F. W. Rogowski. Pp. 107. Boreham Wood, Herts: Fire Research Station, 1960). This contains 1,117 title references to papers, most of which appeared in 1956, arranged under eight headings. The largest section (311 references) is entitled "Initiation and Development of Combustion", and refers mainly to original and fundamental studies. Other sections are devoted to branches of fire technology—occurrences of fire (103 references), fire hazards (106), fire precautions (149), fire resistance (178) and fire fighting (229). Short sections headed "Atomic Energy" (18 references ranging from radioisotopes to nuclear weapons) and "General" bring the volume to a conclusion, except for extensive name and subject indexes which occupy as much as two-fifths of the whole publication and have evidently been compiled with much care and thought. There is no doubt that this series fulfils a useful purpose, especially as regards the fire technology references, most of which would not be found in other bibliographies.

Royal Society Committee on Scientific Research in Schools

The Committee on Scientific Research in Schools which was established by the Council of the Royal Society in 1957 has issued a report covering the period November 1, 1959–October 31, 1960. It is stated that interest shown by schools in undertaking research has continued to increase, and the Committee is now administering research projects in 56 schools. Some of these schools have more than one research project under way and a total of 66 separate research projects are now being actively pursued compared with 57 last year. During the year, £2,000 has been provided by the Council of the Royal Society, and Shell Research Ltd. have given an additional £75 for special assistance at one school. All research projects with which the Committee is dealing are carried out with the specialist advice and assistance of Fellows of the Society and by others who act as advisers. The Committee invites further requests from school-masters and school-mistresses for assistance in undertaking research. A list of the schools at which research projects are being carried out and a list of the projects themselves—which cover a very wide range of topics in the physical and biological sciences—are given as an appendix to the report.

North Atlantic Biogeography

The American Geographical Society, working together with a panel set up by the Committee on Oceanography of the U.S. National Academy of Sciences—National Research Council, proposes to publish a scientific journal of an unusual kind, tentatively called *North Atlantic Biogeography*. The journal will consist of maps, accompanied by such explanatory text as may be necessary, and will appear irregularly as contributions are received and accepted. It will be a medium for publication of studies of all kinds—biological, geological, physical, chemical—that will illuminate our geographical understanding of the marine environment. Its scope will be limited to the Atlantic marine areas from the equator to the pole and will include the Arctic basin. The plan is sponsored in the United States by the National Academy of Sciences—National Research Council, and in Canada by the Royal Society of Canada. Funds are being sought in both countries. The panel is international. Further information can be obtained from the Director, American Geographical Society, Broadway at 156th Street, New York 32.

Botanical Garden, Allahabad

A new botanical garden has been established at Allahabad in the premises of the Central Botanical Laboratory, Botanical Survey of India. The garden is divided into various sections such as an economic plants garden, experimental garden, ornamental section, landscape section, lily pools, fern houses, orchidarium and nursery. The temperature and humidity are being manipulated in the fern houses and orchidarium by artificial fountains and green cover. A variety of species is being introduced in the different sections. The institution is establishing exchange relations for seeds and plants, and it may be possible in the near future to publish an inventory of the seed and plant material available. Gifts of seeds and plants will be welcomed by the Director, Central Botanical Laboratory, Allahabad, India.

Efficiency of Indexing Systems

THE report on the first stage of an investigation into the comparative efficiency of indexing systems issued in September 1960 (see *Nature*, 188, 276; 1960) has now been followed by an interim report on the test programme briefly outlined in that earlier report (Aslib Cranfield Research Project: *Interim Report on the Test Programme of an Investigation into the Comparative Efficiency of Indexing Systems*. (An investigation supported by a grant to Aslib by the National Science Foundation.) By Cyril W. Cleverdon. Pp. iii + 84. (Cranfield: College of Aeronautics, 1960.) 8*s*. 6*d*.). For this programme more than 1,400 questions were received, from which 400 were selected for the first round of testing, about half relating to aerodynamics. Although the test programme is still incomplete and the clerical analysis of such testing as has been done is unfinished, the general level of the four indexing systems is of particular interest and possible surprise. There also appeared to be only a small difference between the success of the postings for the short time of 2 min. as against the relatively long time of 16 min. Comment is also made on the ability of a relatively inexperienced person to index with an efficiency equal to that of the other more experienced members of the staff. Comments on the general level of efficiency are in this report based solely on finding the same document, and indicate that technical staff were able to use the indexes as efficiently as the project staff, the only significant difference being with the alphabetical subject catalogue. Technical staff with no previous experience got on surprisingly well with the Universal Decimal Classification, but in regard to the facet system opinion is provisionally expressed that the chain index and single order approach were a severe handicap and that use of the schedules in a more conventional manner would have given more satisfactory results. Both the project staff and technical searchers found the uniterm system relatively simple to use.

Calcutta School of Tropical Medicine

THE joint annual report of the Calcutta School of Tropical Medicine and the Carmichael Hospital for Tropical Diseases for 1958–59 contains a full record of the work of the scientific staff of the many departments. A number of matters of outstanding importance are referred to. Among these was the breeding of a strain of black mice by the crossing of white and ordinary mice; these were used for transmission of human leprosy bacilli, with promising results. A new experimental device has been evolved for research on amœbiasis. In an attempt to produce better vaccine for cholera, it is recorded that formalin, in a suitable concentration, appeared to preserve antigenicity better than other chemical or physical agents. In the field of virus research, an interesting observation has been made. While the vaccinia virus was invariably found to be lethal to infant mice inoculated intracerebrally, the variola virus was found to survive in the brain of mice for a prolonged period without producing any pathogenic effect. Intensive work continued on the hæmoglobinopathy syndrome, yielding results of considerable interest.

Medical Aspects of the Kariba Dam

A SPECIAL supplement of the *Central African Journal of Medicine* describes medical aspects of the Kariba Hydro-Electric Scheme (6, No. 10; October 1960). The paper has been prepared by Dr. M. H. Webster, formerly chief medical officer to the Federal Power Board, Kariba, who outlines the measures taken to deal with the health problems of the Kariba scheme stemming from the following factors: the topographical and meteorological features of the site; the nature of the undertaking; the importation of African workers in large numbers and at high speed from many parts of Central Africa; the importation of large numbers of European operatives who could be expected to have little or no immunity to the specific disease risks likely to be encountered and, indeed, as it turned out, little or no experience of tropical conditions. One of the first undertakings of the Board was a campaign, carried out from the air and on the ground, against the tsetse fly and mosquitoes which infested the area. As soon as possible an adequate hospital was built, but its modern equipment and comprehensive facilities would have been of little use without the skill and devotion of its staff. In a foreword, Sir Duncan Anderson, chairman of the Federal Power Board, states his belief that the study will prove a valuable source of information and guidance to all engineers and administrators who are concerned with the planning of great projects in the remote corners of the Earth.

The Quelea

IN many regions of Africa the quelea bird has always been a threat to agriculture, causing damage to crops, especially sorghum, millet, rice and other small-grained cereals. The economic losses have increased considerably during the past fifteen years or so, and to-day, in many African countries, more especially those of West Africa, all attempts to raise output are doomed to failure unless methods for the effective control of these birds are jointly elaborated and simultaneously applied. This was the problem before the symposium arranged by the Commission for Technical Co-operation in Africa South of the Sahara, held at Bamako during May 17–21 (*Science Afrique*, 21; July 1960). The agenda covered three main points: a review of progress achieved in control techniques—chemical, physical and biological means of destruction of roosts and breeding colonies; co-ordination at regional and interterritorial level—co-ordination concerning local migrations, ringing campaigns, direct exchanges of information on biology and control between neighbouring territories; control of birds other than quelea presenting a threat to crops. The participants were also called on to consider the possibility of developing joint action in Africa to combat this natural scourge. In their recommendations, they pointed out that progress in quelea control must depend on adequate financial means to apply really effective measures. The meeting also stressed the importance of direct exchanges of information between technicians working in this field, and more especially between technicians in contiguous regions. A ringing programme was recommended to include at least 100,000 birds over a period of three years, and a budget drawn up for such a programme. Another recommendation dealt with the need for investigations on the physiology and parasitic diseases of quelea as being indispensable in determining fresh control methods.

New Stomatopod Crustaceans in West Africa

In November 1956, Dr. D. T. Gauld, of the University College of Ghana, sent to the British Museum (Natural History) three small Stomatopods, collected at Labadi, West Africa. One of these proved to be an immature specimen of a *Lysiosquilla*; the other two specimens were labelled *Squilla pallida*, but this identification proved to be incorrect. Later, two further specimens identical with those submitted by Dr. Gauld were found among a collection of *Squilla africana* Calman from Accra. It was apparent that these four specimens belonged to an undescribed species of *Squilla* as they did not agree with any known West African species, or with the descriptions of any of the known Eastern Atlantic ones. The name *Squilla labadiensis* has been given to this new species, which is described by R. W. Ingle in the September issue of *Annals and Magazine of Natural History* (2, No. 21; 1960). During the course of describing *Squilla labadiensis*, Ingle re-examined several West African specimens of *Squilla* in the British Museum (Natural History) collections. In particular, among a collection presented to the Museum by Mr. A. R. Longhurst, it was discovered that several specimens labelled *Squilla mantis* had been wrongly determined, and these specimens were identified as *Squilla intermedia* Bigelow, hitherto known only from the Gulf of Mexico and Little Bahama Bank, and the range of which is now extended to the West African coast. The description of *Squilla intermedia* is included in the paper.

Canavanine in Leguminosae

The amino-acid canavanine is known to be present in the free state only in members of the Leguminosae. It occurs in the seeds and its synthesis has been reported in rooted leaves of *Canavalia* sp. Its presence can be detected by simple chromatographic techniques. B. A. Birdsong, R. Alston and B. L. Turner have now reported on a systematic study of the distribution of this substance in 161 species, representing 78 genera, of Leguminosae, and have discussed the impact of their findings on the phyletic grouping in this family. These results are supplemented by data, variously collected, by other authors, to yield a total of 219 investigated species representing 109 genera. Of these, 68 species belonging to 32 genera have canavanine in their seeds. Canavanine has not been found in the sub-families Mimosoideae or Caesalpinioideae. In the sub-family Papilionoideae it has not been found in the tribes Podalyrieae and Sophoreae. At least one species from each of the other tribes produces canavanine. In three genera, some species produce canavanine whereas others do not. These data are presumed to be of taxonomic significance and have been interpreted as support for chromosomal information, indicating that the tribes Mimosoideae and Caesalpinioideae diverged relatively early from the 'stem' line which is now represented by the Papilionoideae (*Canad. J. Bot.*, 38, 499; 1960).

New Nature Reserve

The Nature Conservancy has declared a new national Nature reserve of 1,363 acres at Invernaver, near Bettyhill, on the north coast of Sutherland. The reserve includes woodland, heath and sand-dunes. Its subsoil is limestone, and this brings in a number of rare and local plants, including the Scottish primrose *Primula scotica*, the mountain avens *Dryas octopetala*, and the purple mountain milk-vetch *Oxytropis halleri*. The attractive little spring squill *Scilla verna* also grows in the reserve, and there is a moss that grows nowhere else in Britain. The breeding birds of the reserve include the greenshank, red-throated diver and ring ouzel.

Symposium on Zooplankton Production

Following the success of the symposium on primary plankton production held in Bergen in 1957, it is proposed to hold a symposium in Copenhagen in 1961 entitled "Zooplankton Production". It will be held towards the end of the annual session of International Council for the Exploration of the Sea during October 8–10. The symposium is planned to include: two sessions on methods of estimating zooplankton, methods used at sea and in the laboratory, methods of assessment of standing crop and production; one session on the food of zooplankton, the trophic relationships of the organisms, and regeneration of nutrients; one session on behaviour, including vertical migration, distribution, speed of movement and zooplankton as a possible source of sonic scattering layers; one session left open for extra papers and discussion of recommendations. To keep within the schedule, and yet allow time for the very valuable discussions, the papers at the first four sessions will be by invited speakers only. Papers for consideration for the fifth session will be welcomed, at this stage by title only with a paragraph of explanation if this is not clear in the title. The organizing committee includes: Dr. J. H. Fraser (convener), Marine Laboratory, P.O. Box 101, Victoria Road, Aberdeen; Prof. E. Steemann Nielsen (Copenhagen); Prof. J. Krey (Kiel); Dr. Gunnar Thorson (Helsingør). Those who intend to be present should notify the convener as soon as possible.

"Educating the Whole Man"

In an article, "The Problem of Freedom and Efficiency in Universities", in *Science and Freedom* for October and in a broadcast talk, "Dry Rot and Redbrick", Dr. A. P. Rowe pleaded earnestly for a thorough reconsideration of the relations between teaching and research in British universities. He suggested a searching inquiry into the quality of both, as well as into the balance between them, and also that changes in the structure of the administration of the universities might facilitate the promotion of more effective and stimulating teaching, and the elimination of much of the trivial investigations which now pass for research. A sentence in the leading article in *Nature* of January 7 (p. 2) unwittingly misrepresents Dr. Rowe's mind. So far from rejecting any idea of a broad education, he is concerned that the universities of Great Britain are failing to provide that vital something that was once given by the homes from which their students came; and although he advocates that more research should be carried out in research institutes rather than in university departments, such institutes should be, he thinks, an integral part of the university.

D.S.I.R. Studentships, Fellowships and Research Grants: 1961

Two booklets, issued by the Department of Scientific and Industrial Research, have become available and give detailed information on grants to be offered by the Council for Scientific and Industrial Research during 1961 for studentships, fellowships and special research. The first, entitled *D.S.I.R. Studentships and Fellowships, 1961,* gives the information required by young scientists and technologists who wish to obtain grants in order that they may continue their training beyond their first degree (Pp. 28. London: H.M. Stationery Office, 1961. 1*s.* 9*d.* net). Information is also given of awards made available by the Council and tenable abroad, and of Nato science studentships and fellowships. In most cases it is required that applications for these grants be made by March 1. The second booklet, entitled *D.S.I.R. Research Grants, 1961,* gives information on grants for special research work (Pp. iv + 8. London: H.M. Stationery Office, 1961. 1*s.* net). This covers such grants as are applicable to investigators who are already of acknowledged standing in their subjects. Applications for these grants should be submitted to the Council by May 1 or November 1. Grants issued by the Department of Scientific and Industrial Research are essentially for British subjects normally resident in the United Kingdom, but in certain cases the Council will consider persons of other nationalities who are working in the United Kingdom.

Lady Tata Scholarships and Fellowships

The Trustees of the Lady Tata Memorial Trust invite applications for grants, scholarships and fellowships for research on diseases of the blood, with special reference to leukæmia, in the academic year beginning October 1. In view of the affinity between leukæmia and other forms of neoplastic disease, candidates with programmes of research on any aspect of malignant disease which may throw light on problems of leukæmia will be eligible for consideration. The Trustees specially wish to encourage studies of the leukæmogenic viruses in mammals, the epidemiology and natural history of leukæmia, and the genetical and cytological aspects. Further information can be obtained from the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, S.W.3. Applications must be submitted before March 31.

"Radiative Recombination in Gallium Phosphide Point-Contact Diodes"

Drs. H. C. Gorton, J. M. Swartz and C. S. Peet write: "The acknowledgment to the United States Air Force, which sponsored the work reported in the communication under this title published in *Nature*, 188, 303 (Oct. 22, 1960), through subcontract with the Lincoln Laboratory, Massachusetts Institute of Technology, was inadvertently omitted. Appreciation is hereby expressed to the Lincoln Laboratory for permission to publish this work".

"Labilization of Deoxyribonucleic Acid in Thymus Nucleoprotein after Whole-body Irradiation"

Referring to the communication under this title in *Nature*, 187, 1123 (1960), Dr. Ulrich Hagen writes: "In the text, Fig. 1 and in Tables 1 and 2, the extraction of DNA is described as being done with 'trichloracetic acid'. It must be emphasized that the sodium salt of trichloracetic acid was always used, at the concentrations mentioned (0·5, 1·0 ... per cent). The *p*H-value of the solution was 6·7".

Announcements

Prof. Theodore von Kármán, at the California Institute of Technology, has been awarded the 1961 James Watt International Medal of the Institution of Mechanical Engineers, in recognition of his contributions to the advancement of mechanical engineering science in the field of aeronautics. The award of the Medal is made every two years.

Dr. E. K. Janaki Ammal has been awarded the Indian Botanical Society's Birbal Sahni Medal. The Medal is awarded every year to a distinguished Indian botanist for his contributions and services to botany in India.

Volume 4, Part 4, *of Scientific Institutions and Scientists in Latin America*, issued by the United Nations Educational, Scientific and Cultural Organization, Scientific Co-operation Office, Montevideo, lists the scientists of Argentina, *N–Z*, giving the usual particulars of career, research activities and publications (Pp. 453–706. Montevideo: Unesco, Centro de Cooperacion Cientifica para America Latina, 1960).

Industrial Abstract, No. 47 (November 17, 1960), issued by the Technical Information Section, Federal Ministry of Commerce and Industry, Lagos, Nigeria, includes the abstracts classified according to the Universal Decimal Classification, indicated by its title. There are also a review of the fourth edition of the *Handbook of Commerce and Industry in Nigeria* and a list of industrial, scientific and commercial fairs, exhibitions and conferences, November 1960–February 1961 (Pp. ii + 26. Lagos: Federal Ministry of Commerce and Industry, 1960).

The Clay Minerals Group of the Mineralogical Society is holding a joint meeting with the British Society of Soil Science in the School of Agriculture, University of Cambridge, during April 6–7. The subject for discussion will be "Weathering". Further information can be obtained from Dr. R. M. S. Perrin, School of Agriculture, University of Cambridge.

The Advisory Committee on Arid Zone Research and the World Meteorological Organization are jointly organizing a symposium on "Changes of Climate" at the headquarters of the Food and Agriculture Organization, Rome, during October 2–7. The symposium is being arranged with special reference to Arid Zone Research. Further information can be obtained from W. Moller, Arid Zone Unit, Department of Natural Sciences, Unesco, Place de Fontenoy, Paris-7e.

A conference is being organized jointly by the Colour Group, the Institute of Physics and the Physical Society and the Inter-Society Color Council of America, to celebrate James Clerk Maxwell's demonstration of trichromatic colour reproduction at the Royal Institution in London. The conference will be held at the Imperial College of Science and Technology during May 16–18. Further information can be obtained from the Institute of Physics and the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

SCIENCE PLANNING, DEVELOPMENT AND CO-OPERATION IN THE COUNTRIES OF THE MIDDLE EAST AND NORTH AFRICA

A REGIONAL conference on the above topic was held under the auspices of Unesco and the United Arab Republic Science Council in the Senate Hall of the House of Representatives, Cairo, during December 19–23. The meeting was organized by the U.N. Science Co-operative Office of the Middle East (director, Mr. Jan Smid) and the United Arab Republic Science Council (secretary-general, Dr. A. F. Ismail). The meeting was attended by delegates from Iraq, Jordan, Lebanon, Morocco, Sudan, Tunisia, Turkey and the United Arab Republic. Three international scientific consultants were in attendance —Prof. J. Coulomb, directeur-général, Centre National de la Recherche Scientifique, Academician M. M. Dubinin, Academy of Science, U.S.S.R., and Prof. M. Stacey, Mason professor and head of the Chemistry Department, University of Birmingham.

The meeting was opened by an address of welcome from the Egyptian Central Minister of Education, His Excellency Kamal El Din Hussein, who discussed the need for co-operation in science and technology at regional and international level, and who emphasized the importance of such a conference for the future development of Middle Eastern and North African countries.

He was followed by Mr. Jan Smid, who spoke of the role of Unesco in the development of scientific research throughout the world. He outlined Unesco's efforts in trying to solve problems of economic planning in the less-advanced countries. He indicated the aims of the Conference as being of particular value in assisting the delegates to set up in their own countries some form of permanent centralized national body for co-ordination of scientific research aimed at better economic development of natural resources.

He emphasized the role of the international consultants. They were present to give their views on science administration based on their experience.

Each of the consultants then gave a short address on science planning and administration within his own country.

After an intermission, Dr. M. A. Haseeb of the Sudan was elected chairman of the conference and the elected vice-chairmen were delegates from Iraq and Turkey. Dr. A. F. Ismail of the United Arab Republic was elected recorder of the meeting. During the following two days delegates gave extensive reports on what was happening in science in their own countries. These may be summarized as follows:

Iraq. Delegates Dr. A. T. Al-Najim, director-general of education, Baghdad; Dr. F. Al Tai, dean of science, University of Baghdad.

The University of Baghdad was prominent in leading some research activities, and there were two research institutes in the country. Studies in agriculture and forestry were prominent and so were science and medicine. A number of research centres for industry, for example, for petroleum chemistry, were already planned, and schemes were in hand for atomic studies. There was a serious lack of trained scientists and technicians. Much thought was already being given to planning the national effort.

Jordan. Delegates Dr. S. Nashef, director of research, Ministry of Agriculture; Mr. A. Fouzi, under-secretary, Ministry of Public Works.

Jordan had no university, but there was a growing awareness of the importance of scientific research for the future development of the country. Various ministries had undertaken important research projects, for example, in agriculture, health, public works, etc. The Jordan Development Board, through its planning committee, was undertaking much research. Many industrial firms such as the Potash Co. were applying results of research. Many students were being trained abroad.

The country was beset with many difficulties. There was an urgent need for a central body for co-ordinating and financing research. There was a serious lack of scientists and trained technicians and a need for raising the status and salaries of those they had at present.

Lebanon. Delegates Mr. Joseph Naggar, president of the Central Scientific Commission for Lebanon; Dr. M. Attie, director, Industrial Research Institute.

There were three universities in Lebanon: (1) The Lebanon University, a recent foundation with quite well-equipped laboratories for research, especially in chemistry, physics and biology. (2) The American University with well-equipped science laboratories and with attached Schools of Engineering, Medicine, Agriculture and Economics. (3) The University of St. Joseph—a French University with good departments, but now lacking in funds.

There are a number of research institutes and also two good observatories. Scientific research in Lebanon lacks co-ordination, and urgently needs planning at the national level.

Morocco. Delegate Dr. Abdel L. Bennis, director, Agronomical Research Centre of Rabat.

There are a number of scientific research institutes in Morocco, for example, the Laboratory of Chemistry and Physics with divisions of hydrology, biological chemistry, hygiene, etc. There are also Laboratories of Parasitology, Entomology, Microbiology and General Biology. There are Departments of Botany, Chemistry, Geology (with an Institute of Geology) in what is termed the Faculty of Science of Morocco. An Agricultural Research Institute is under the care of the Ministry of Agriculture. There is a scientific institute, L'Institut Scientific Cherifeon, which was founded in 1921 with the object of co-ordinating science, and it has done valuable work in many disciplines and has given help with founding libraries, museums, etc.

There is a great need for a central science council for which the Government has now given approval. There was a grave shortage of scientists and technicians.

Sudan. Delegates Dr. M. Ali Haseeb, assistant director of research, Ministry of Health; Mr. A. A. El Karib, assistant director, Ministry of Animal Resources.

This country has 11 million people spread out over a million square miles. Its climate varies from desert to tropical and subtropical and it has rich natural resources of minerals and agricultural products. Cotton is the main export.

The University of Khartoum is well established, and is very active in many faculties such as Science, Agriculture, Engineering, Veterinary, Arts and Law. A good deal of research is applied for national needs. There are many institutes of the various ministries which carry out research, for example, Agriculture, Irrigation, Animal Resources, Tropical Medicine. The Government is sympathetic to potential developments through science. Many more scientists and technicians are needed in the country.

Tunisia. Delegates Mr. Hamza, head of the Faculty of Sciences, director of research on arid zone problems, University of Tunis; Mr. Talbi, professor, Faculty of Letters and Science, University of Tunis.

The country has some traditions in science, for the Pasteur Institute of Tunis was created many years ago. Researches in the natural sciences, etc., have been carried out in institutes under various ministries, for example, of Education and Agriculture. Connexions with France have been close, and results of researches have been published in French scientific journals. Now a University of Tunis has been created (March 1960) which, although needing 10 years to build, will cater for 15,000 students and will have powerful science faculties and research facilities. The general outlook for science collaboration in Tunisia is promising.

Turkey. Delegates Prof. H. N. Pamir, University of Istanbul; Prof. N. Serdaroglu, Technical University, Istanbul.

Scientific research is carried out in the Universities, in laboratories attached to ministries and at a few special institutes. There are six Universities—Istanbul, Ankara, d'Ego, Ataturk, the Technical University at Ankara and the Technical University of Istanbul. Between them most scientific disciplines are taught, and research facilities are good. Most specialists' subjects such as agriculture are studied in the Ministry Laboratories, of which there are eight. The special research institutes are medical, for example, for tuberculosis and cancer. Much thought is being given at present to the formation of a council for science, but many difficulties must be overcome.

United Arab Republic. Delegates Dr. A. R. Tourkey, director, National Research Centre, Cairo; Dr. M. M. Ahmed, vice-rector, University of Cairo; Dr. A. F. Ismail and Dr. M. K. Tolba, Science Council; and Dr. M. B. Ahmed, University of Cairo; Dr. Y. Khouri and Dr. S. Al Safadi, University of Damascus.

Comparatively speaking, the United Arab Republic is very well organized, and the powerful Science Council which co-ordinates science in Egypt and Syria has just published its third annual report together with a report to Unesco. Both of these make impressive reading. The five Universities—Cairo, Ain Shams (Cairo), Alexandria, Assiout and Damascus—are all being considerably expanded, especially on the research side. The building of the large science centre in Cairo is well advanced, and there are many other research institutes, for example, for atomic research.

The projects being attempted are largely aimed at developing natural resources and are making good progress. The United Arab Republic is already playing the part of a centre of scientific training for the region. Its own problems, however, are still very great: especially a need for more high-quality scientists to act as research leaders, for skilled technicians, for better information and library facilities, for expensive apparatus, etc.

In the lively discussions which followed, many important and not unfamiliar points emerged. It was clear that there is already a good foundation in most countries on which sound national and regional developments in science can be built. There is urgent need for firm and substantial government support, for fair treatment of scientists and for good co-operation through Unesco.

Finally, it was possible for the conference to pass the following Resolutions:

(1) That a central science council or a similar body should be established in each Member State with the aim of organizing, reinforcing and co-ordinating pure and applied scientific research as well as promoting research projects leading to the economic, social and intellectual development of the nation.

(2) That this council or body has public utility status and financial autonomy, and is directly attached to the office of the Prime Minister, having a limited membership including representatives of universities, interested ministries and scientific institutions as well as certain scientists and experts in industry and agriculture.

(3) That the Member States allocate to this council a sufficient budget which would enable it to accomplish its mission, and that total expenses for scientific research in the country are progressively increased in order to attain not less than 1 per cent of national income.

(4) That this central body should first make use of the existing research institutions by improving their possibilities and promote establishment of new laboratories in fields essential to national needs.

(5) That this council establishes the priority of various projects of applied research of national importance after preliminary study made by special committees formed by the council.

(6) That the council executes the adopted research projects either in its own laboratories or in co-operation with other competent scientific institutions.

(7) That a national scientific documentation centre be established in each Member State, with the aid of Unesco if necessary and on request, which will be attached to the council and charged with providing scientists with the necessary scientific information.

(8) That the Member States undertake adequate training of scientists necessary to the country by strengthening faculties, universities and institutions, and by establishing new ones as well as missions abroad.

(9) That the Member States define and establish the appropriate status of scientific workers together with provision of the material conditions corresponding to the highest scale existing in the country.

(10) That the Member States give attention to the training and improvement of material and moral conditions of auxiliary and technical personnel of laboratories.

(11) That the public and private resources grant housing and financial assistance to universities and institutions of scientific research to enable them to undertake the execution of their projects as is done at present in other countries.

It is recommended to the Member States that such grants are exempted from all taxes.

(12) That the council has a duty to promote regional and international co-operation, to elaborate the scientific parts of bilateral and international cultural agreements and to represent the country in international scientific non-governmental organizations.

(13) That the Member States grant sufficient means for the exchange of their professors and scientific workers and request Unesco to anticipate in its budget for 1963–64 a supplementary provision to accomplish this aim.

(14) That the Member States promote organization of national or regional scientific congresses and symposia as well as participation in international meetings.

(15) That the Member States support their scientific institutions in co-operation with similar establishments in other countries to solve problems of regional or international importance.

(16) That Unesco should continue to promote the organization of symposia and regional scientific meetings to discuss subjects of interest to various Member States.

(17) That all efforts and results reached by science should be used solely to help humanity and to improve the standard of living of the peoples.

(18) The conference thanks the Middle East Science Co-operation Office of Unesco, the Science Council of the United Arab Republic as well as the international consultants, and recommends that Unesco should organize within two years a similar conference to study the progress made in the field of scientific research in the Member States.

ELECTRICAL ENGINEERING IN THE ROYAL NAVY

AT almost the same time as he relinquished, by retirement, the post of director of electrical engineering at the Admiralty, Sir Hamish Maclaren assumed office as president of the Institution of Electrical Engineers. This is only the second occasion on which the chief electrical engineer of the Admiralty has occupied the presidential chair of the Institution. C. H. Wordingham, who became head of the Electrical Engineering Department of the Admiralty in 1903, was president of the Institution during 1916–18.

Very appropriately, in his presidential address delivered on October 6, Sir Hamish reviewed the development of electrical engineering in the Royal Navy. The electronic equipment and control gear of the submarine utilizing nuclear propulsion plant represents the culmination of some ninety years of development of the applications of electricity in naval vessels, the first being the electrical firing of guns. It was, however, nearly twenty years earlier that the Admiralty made its earliest uses of electrical signalling when in 1852 the twenty-two semaphore stations between Plymouth and Whitehall were replaced by an electric telegraph.

The first dynamo was installed in a warship in 1875 to provide power for a searchlight to be used against torpedo craft, and it is probably this early association with torpedoes that established the practice of placing the responsibility for all electrical equipment in ships on the torpedo officer. This practice remained in force until 1946 when the electrical branch was founded.

A combined ship lighting and searchlight installation was fitted in H.M.S. *Inflexible* in 1881, Swan incandescent lamps being connected in groups in series. By 1886 first-class ships were being equipped with three dynamos each supplying 200 amp. at 80 V.

The ring-main system of distribution at 22-V. direct current was introduced in the early years of the present century and remained the standard naval practice until after the end of the Second World War.

It was in 1896 that the remarkable pioneering experiments in wireless telegraph communication between ships were made by Captain H. B. Jackson. Communication was established between H.M.S.'s *Defiance* and *Scourge* over a range of 5,800 yards. In 1899 Marconi equipment with a range of up to seventy miles was installed in four ships.

Experience during action in the First World War focused attention on the impracticability of maintaining so-called watertight enclosures watertight, and means were devised for isolating, automatically, flooded equipment from the supply.

After the War the Admiralty reviewed the experience, to date, of electricity supply in warships and in particular considered the possible introduction of alternating current. Considerable importance, perhaps an undue amount, was attached to the ease and convenience of speed variation of the direct current motor and direct current was retained.

The application of electricity in fire control systems was greatly advanced during the First World War. Individual components such as plotting tables, data transmission and communication instruments had, however, been developed largely by individual specialist firms, giving rise to diversity of design and practice.

It was towards the end of the First World War that the gun director system was introduced in which a gyroscope was employed as a stable reference to ensure that the guns fired only when the ship was in a horizontal position during rolling. This was a prelude to the day when directors and gun mountings would themselves be stabilized.

Between the two World Wars action was taken towards achieving uniformity of practice in instrumentation. Much effort was directed towards the design of fire control computers, and, as the importance of air attack increased, to the special problems associated with the control of high-angle anti-aircraft guns. Of the work done at the Admiralty Research Laboratory during that period mention should be made of the plotting table which automatically records the ship's position on a chart, of the 'magslip', a data-transmission unit of much greater accuracy than any other available at that time, and of an electrically controlled oil-operated remote-power system for searchlights.

The outbreak of the Second World War produced immediately the problem of combating the novel and ingenious devices which had been developed by the enemy. The first was the magnetic mine. Real success in sweeping the magnetic mine was achieved with the development of the towed buoyant-cable sweep whereby a relatively large magnetic field is produced in the sea by circulating current pulses of several thousand amperes round the loop of buoyant cable.

The degaussing of ships, at first effected by a single-turn coil embracing the hull, was, after considerable research, shown to be practicable with multi-core cable fitted inside the hull.

H.M.S. *Belfast*, damaged by a magnetic mine explosion in October 1939, exhibited extensive damage to electrical equipment from underwater shock. The shock accelerations and displacements resulting from non-contact under-water explosions were of a much higher order than those against which the equipment had been designed, and an extensive programme of experiment and of redesign of electrical equipment and of shock-proof mountings was undertaken.

The loss of the *Ark Royal* in November 1941 brought to light further important factors in the vulnerability of the electrical systems of warships. A hit by a single torpedo had the disastrous result of flooding one boiler room and the main switchboard room. The remote control of circuit breakers from the main switchboard was based on a system which the flooding rendered completely inoperative and services could not be restored although power was available for some time. Even the power supply was dependent, as the generators were driven by steam turbines, on the ship's main boilers. The redesign of the control system introduced relay control, energized from independent local supplies, and auxiliary diesel generators were provided.

Electrical actuation in the training and elevation of anti-aircraft guns was initiated in 1939, utilizing the rotating amplifier machine known as the 'metadyne', controlled by a magslip-data transmission system to which reference has already been made.

The introduction of radar for range-finding produced automatic following of the radar aerial so that the aerial, the gun director and hence the gun automatically followed the target. Fully automatic following of the target was achieved by designing the radar to provide its own misalignment signal and feeding the necessary additional information from the fire control computer and the stabilizer.

The action information centre has become the most concentrated part of the electrical installation of a warship. It is the focal point for radar and asdic information, for external and internal communication, aircraft and weapon direction and for navigation.

Alternating current was adopted in 1948 for all ships larger than mine-sweepers. Simplicity, reliability and the necessity to save space and weight in the large and complex electrical systems required made the advantages of alternating current supply overwhelming.

A supply frequency of 60 c./s. was adopted for the 440 V. three-phase system. The higher frequency of 60 c./s., in place of the standard power frequency of 50 c./s., had the great merit of a substantial reduction in the size and weight of machines and a higher maximum speed of 1,800 revolutions per minute. There was the added advantage of a common standard with the U.S. Navy. There is, of course, the disadvantage of more complex equipment where continuous variation of speed is required. Automatic voltage regulation is required, and a standard type of automatic voltage regulator utilizing a magnetic amplifier has been developed which can be used with generators of 150-kW.–1,500-kW. capacity.

Nuclear propulsion has revolutionized the performance of the submarine, which becomes at last a true submarine rather than just a submersible vessel. The nuclear submarine must, however, still have a battery for starting up and emergency standby although of smaller size than that for the conventional submarine. Because of the possibility of prolonged submerged operation, some of the battery problems encountered with conventional submarines became of even greater importance. The evolution of hydrogen on open circuit can be reduced by the use of grid alloys having a very low antimony content. Antimony-free grids would at the same time eliminate the production of the highly toxic gas, antimony trihydride, or stibine.

The electrical installation of the nuclear submarine is in fact much like that of the surface vessel with the addition of an electric drive of small power for emergency use. As in the surface vessel, an increasing amount of electronic and servo equipment is required, and there is in addition the equipment for reactor control and instrumentation. It is in the submarine, because of the acute limitation of space, that semiconductor devices offer special promise in their future application.

J. Greig

POWDER METALLURGY

An international conference on "Powder Metallurgy", sponsored by the Metal Powder Industries Federation and the Metallurgical Society of the American Institute of Mining and Metallurgical Engineers, was held in New York during June 13–17. At sessions throughout the first three days, papers were presented by authors and briefly discussed. Visits to plants were made during the last two days. The meetings were well managed and held to a precise time schedule which allowed little time for informal discussion. The hall, with a seating capacity of about four hundred, was filled for every session.

Dr. P. Schwarzkopf, honorary chairman of the conference, opened it with a review of a half-century of modern powder metallurgy, which he considers to have developed since Coolidge's paper of 1910 on the powder metallurgy of tungsten. He regards earlier powder metallurgy, such as that in pre-history, that by the Incas, and the British and Russian work on platinum, as detached from the development of modern technology to which they made little contribution. Powder metallurgy was a forgotten art at the start of this century, although in 1898 Welsbach patented its use to make osmium filaments. Coolidge's tungsten filaments were the first really usable product of modern powder metallurgy. Cemented carbides manufactured by powder methods came in 1922.

Work on the nature of the sintering process appeared in 1922 when Sauerwald published his first paper on the subject, which he thought of as a recrystallization process. Important later work on the theory of sintering included Russian papers published in 1945 and the work of S. P. Slater and G. C. Kuczynski. In recent times the latter worker has dominated thinking in this field.

Several papers at this conference made it clear that work on the theory of sintering is once again coming to life. It is now appreciated that we must not seek one dominant sintering mechanism for all materials, or even for one material at all stages of the sintering process, or in all circumstances in which sintering takes place. Kuczynski (University of Notre Dame) emphasized this by stressing the convenience of considering separately the two extreme stages of sintering when seeking to explain what occurs: these are: (1) the formation of necks between particles at the start of sintering, and (2) the disappearance of isolated pores towards the end of the process. The first stage is now fairly well understood, but the second is more complex and difficult to cope with. Unbalanced forces in the necks lead to flow of material in a viscous or plastic manner. He has shown that, if x is the diameter of the neck between sintering particles, and a the diameter of the particles, x^n/a^m is a function of time and the values of n and m are characteristic of the sintering mechanism which is operating:

$n =$	2	3	5	7
$m = 1$	Viscous or plastic flow	Evaporation and condensation	—	—
2	—	—	Volume diffusion	—
3	—	—	—	Surface diffusion

Recent observations of the sintering of copper wires twisted together show that volume diffusion is in this case the main mechanism. Kingery has shown it to be evaporation and condensation in sodium chloride. In glass it is viscous flow. Sintering of nickel at 1,400° C. is due to volume diffusion and that of iron at 850° to surface diffusion. Kuczynski described a very pleasing experiment on the sintering of copper-8 per cent indium. Indium diffuses more rapidly than copper in this alloy and where its concentration rises an indium-rich δ-phase forms. This phase was found in the necks between sintering particles, an observation confirming that diffusion is a mechanism of the sintering in this case.

The importance of grain boundaries is not yet clear. A. L. Pranatis and L. L. Seigle examined the sintering of iron, copper and nickel and observed the radius of the neck between particles to be proportional to time whether boundaries were present or not. However, they found that reduction did not occur in the volume of isolated voids in nickel at 1,400° C. unless boundaries ran into them, whereas B. H. Alexander and R. W. Baluffi observed shrinkage of voids within metal single crystals.

A few years ago M. Eudier reported that additions of hydrogen chloride to the sintering atmosphere accelerated the sintering of iron powder and improved the properties of the product. More recently J. Vacek described the spectacular effect of a trace of nickel in causing tungsten to sinter at half the temperature required for pure metal. Considerable interest was shown in such activated sintering, the practical significance of which is clear. That the nature of the sintering atmosphere may determine which sintering mechanism dominates a particular case was illustrated by Kuczynski's observation that single crystal particles of alumina sinter by volume diffusion when heated in helium containing a little oxygen, but by viscous flow in dry hydrogen.

J. Wulff (Massachusetts Institute of Technology, Cambridge, Mass.) has studied the effect of nickel on the sintering of tungsten. He reminded the conference that this remarkable effect was known to von Bolton long ago, but has been overlooked until very recently. Wulff found that additions of nickel are increasingly beneficial so long as a monatomic layer over the tungsten particles is being built up, but not after sufficient metal for this is present. He attributes the effect to diffusion of tungsten through the nickel. F. Eisenkolb (Technische Hochschule, Dresden) found additions of about 2 per cent of calcium fluoride to iron or steel powder to improve its sintered strength, but that larger additions reduced this.

It would be very interesting to know what effect these additions have on the Kuczynski coefficients of the sintering metal.

Kuczynski recalled attention to phenomena when two metals sinter together. Thus when copper and nickel are in contact at 1,020° C. the copper particles shrink and pits form in them near junctions with nickel, while the nickel particles expand. This is explained by the more rapid diffusion of copper than of nickel.

G. A. Geach and A. A. Woolf (Associated Electrical Industries, England) have examined a number of pure crystalline organic materials of widely differing molecular shapes and found that these did not sinter at 0·8 of the absolute melting points, although they show creep deformation at lower temperatures. It is not clear whether this should be attributed to an absence of self-diffusion of large molecules or to the low surface energy of such materials. Although nylon sinters it is interesting that it does so more slowly if the threads are stretched so that the material becomes more crystalline. It was reported that in commercial practice amorphous precipitated nylon is found to sinter more effectively than ground material.

Developments were reported in many techniques of powder metallurgy. Although hydrostatic pressing of powder in a rubber sack was patented in 1913 much attention is now being given to this method. H. H. Hirsch and C. E. van Buren (General Electric Co.) reported that pressing vessels up to 20 in. in diameter and several feet long now exist, and that pressures up to 50 t.s.i. can be used, although it is now known that for each material there is a pressure above which little advantage is gained (30 t.s.i. for tungsten, 4·5 t.s.i. for alumina). Isostatic pressing to finished form in shaped moulds of rubber or reversible gel is extending, and may lead to economy when only moderate numbers of parts are required. Slip casting of metal powders in porous moulds is also being developed, and A. Poster (Sylvania Electric Products) described freezing the mould at 29° F. to remove the casting safely, and then drying it for two days in fuller's earth because rapid drying damages the surface. Hot extrusion of metal powder is particularly valuable when pyrophoric powders, or those involving a health hazard, are pressed while in a closed can. Developments in the direct rolling of metal powder to strip which were described included the use of heated rolls. Rolls of very large diameter are desirable for compacting powders, and an interesting technique described used two rings of large diameter of metal which were threaded about the 8-in. rolls of a smaller mill and operated as large rolls.

The use of an explosion to drive the ram of a mould pressing powders will give pressures of 10^6 p.s.i. for microseconds: R. A. Cooley (Propellex Division, Chromalloy Corp.) reported improved properties of products pressed in this way. A remarkable result claimed is nickel of density one per cent higher than the crystallographic value.

A large amount of work on dispersion-hardened materials was reported, and at present interest is greatest in materials based on aluminium, copper or nickel. It appears that the dispersed phase should be hard and that interfacial energy between it and the matrix should be low: thus thoria particles in titanium alloys have little effect unless the alloys wet the particles. Dispersed particles should be of irregular shape, not rounded, for greatest effect. F. V. Lenel and G. S. Ansell (Rensselaer Polytechnic) stated that the yield stress of these materials is determined by the stress which fractures a dispersed particle, and that it is inversely proportional to the square root of the spacing between particles.

SAP alloys (aluminium strengthened by dispersed oxide) are now known which can be rolled either hot or cold or which can be drawn and pressure-welded.

M. Eudier (Metallurgie Française des Poudres) reported that a controlled oxidation of nickel before sintering raises the density achieved, and he explained that the effect is due to filling of certain pores with oxide and later reduction of this without re-formation of cavities.

The powder metallurgy industry is expanding rapidly. The use of iron powder showed an upsurge during 1954–55, and in 1960 was three times that in 1956. Application of powder methods to beryllium is now important, and the plant to handle a large amount exists. Consolidation of powder in cans by quick blow-forging is important and disks 12 in. in diameter by 1·5 in. thick are made in this way. Beryllium foam made from fine powder, and the production by hot pressing of metal beryllide parts which have high thermal conductivity, are novel developments. Very large pieces can now be manufactured by powder methods: F. Emley (Westinghouse Electric Corp.) noted equipment for hot-pressing beryllium billets up to 60-in. diameter, and the production of molybdenum billets 40 in. × 3·5 in. × 3·5 in.

G. A. Geach

SOIL FAUNA IN RELATION TO SOIL FORMATION AND FERTILITY

THE study of soils has for long been the province of pedologists, chemists and microbiologists, and, apart from isolated instances, it has only been during the past fifteen years or so that the subject has attracted attention from zoologists in Britain. During the 1955 Easter School held by the School of Agriculture, University of Nottingham, many soil zoologists from Europe as well as Britain were brought together. This was succeeded during 1958 by a three-day international colloquium held at Rothamsted Experimental Station and devoted to "Progress in Soil Zoology". These have given new stimulus to the subject, and the recent symposium on "Soil Fauna in Relation to Soil Formation and Fertility", held by the Association of Applied Biologists, indicates the still growing interest which soil zoology is arousing. This symposium was held on October 14 at the British Museum (Natural History), where the new lecture theatre is eminently suitable for such meetings.

The theme was introduced and summarized by G. V. Jacks, director of the Commonwealth Bureau of Soils. He started by giving numerical evidence of the increasing number of publications on soil zoology appearing in *Soils and Fertilizers*: during 1937–40 there were three, during 1953–56 thirty, and during 1956–59 ninety. The part played by biological processes in determining soil fertility was then put in perspective. Under natural conditions soil animals are complementary to plants and necessary for operating the cycle of nutrients effectively. They are important factors in breaking down plant litter, mixing it with the soil and creating the porous texture characteristic of good soils.

The first paper was given by Dr. D. A. Osmond and Mr. P. Bullock, of the Soil Survey of England and Wales, on "Soil Fauna in Relation to Pedology". The condition of a soil is the result of many factors of which the fauna is but one. The influence of animals is difficult to assess in arable land, but may be very great in grassland and forest soils. Their effects range from the burrowing of mammals to the incorporation of quantities of plant material into the soil by the mesofauna. Dr. Osmond then described different soil-types with the aid of photographs of thin sections. Peat represents one end of the scale where plant matter is virtually unattacked by the fauna, and with increasing faunal influence one passes through moder and mull soils, finally culminating in the vermisols possibly found in parts of north England which are the result of intense earthworm activity.

The mechanics of earthworm influence were pursued by Dr. F. Raw, from Rothamsted Experimental Station, by a consideration of leaf burial in apple orchards. Comparisons were made between sprayed and unsprayed orchards, some under arable cultivation and others under grass. For sampling earthworm populations dilute formalin was found more efficient than permanganate, and in the seven orchards investigated six dominant species were found. Of these, pot experiments showed that only *Lumbricus terrestris* was responsible for pulling leaves into its burrows. Quantitative studies showed, moreover, a close relationship in the grass orchards between weight of *Lumbricus terrestris* populations and the percentage disappearance of leaf litter from cages. The rate of disappearance was inversely proportional to the amount of surface vegetation, being greatest in the arable orchards.

In grass orchards which had been sprayed with a copper fungicide for many years, the earthworm fauna was reduced to a single species living in the surface litter. Here leaf decomposition was very slow and the soil profile had typical mor characteristics.

Some aspects of work being carried out at the University College of North Wales, Bangor, were described by J. Hobart and A. J. Hayes. The former gave a paper on the distributional patterns of soil mites in pure and mixed stands of conifers. In the apparently uniform habitat of a Douglas fir plantation (*Pseudotsuga taxifolia* Britt.), only eight out of thirty-two common species of mites (adults) did not show a significantly aggregated distribution. Samples were taken along radiating transects from trees, and several species of mites were found to have very definite and different preferences for particular radial distances. These may be due to differences in the thickness of the litter layer and in moisture content, and are evidence of very sensitive discrimination.

In mixed plantations, again, distinct populations were found in relation to spruce (*Picea* sp.), Scots pine (*Pinus sylvestris* L.), larch (*Larix* sp.) and silver fir (*Abies alba* Mill.). The numbers under spruce were generally lowest, and a few species showed definite preferences for larch or silver fir.

Hayes described some work on feeding behaviour of Oribatid mites using mainly *Hoploderma magnum*. Colonies were kept at constant temperature maintained at three different humidities and fed on weighed quantities of needles from three species of conifer. These needles were graded into three categories of age and condition. After 72 hr. the remains were re-weighed and the number of fæcal pellets counted. Measurements were made on eight replicates of fifty individuals for each treatment. Production of fæcal pellets for all three species appeared to be greatest for fallen but still entire needles and least for fresh green needles. Analysis of variance showed, however, that few of the differences between humidities, tree species or conditions of needles were significant. Preliminary results indicated that there was no correlation between loss in dry weight and the number of fæcal pellets produced, and loss in dry weight of needles did not appear to give a satisfactory index of feeding.

As part of the concerted work on woodland soils by the Nature Conservancy at Merlewood Research Station, K. L. Bocock described some work concerned specifically with the comparative rates of disappearance of oak (*Quercus petraea* Liebl.) and ash (*Fraxinus excelsior* L.) leaves on contrasting sites. Weighed quantities of leaves were placed on the ground in nylon hair-nets and sampled periodically over 14 months. As a result of earthworm activity ash leaves on a mull soil disappeared most rapidly, with loss in nitrogen following closely the trends of loss in dry weight. On a moder soil the loss of nitrogen was relatively less rapid. Oak leaves on mull showed an actual increase in nitrogen content; possible explanations were the presence of nitrogen-fixing micro-organisms, absorption of nitrogen compounds from the rain or contamination with slime and droppings from soil animals.

Feeding experiments with *Glomeris* (Diplopoda) on hazel leaves (*Corylus avellana* L.) showed that the amount of water-soluble nitrogen was larger in the fæces than in the food, largely due to an increased ammonia content.

The symposium ended with a synoptic point of view of invertebrate metabolism and its effect on soil fertility. With the aid of diagrams, A. Macfadyen depicted the main paths of energy-flow in a typical grassland soil as a result of the direct metabolic effects of the fauna. Calories entering the system from sunlight pass through various levels (corresponding to successive links in food chains) at each of which some energy is dissipated in respiration. The proportions received and passed on by different groups of organisms and, in the case of agricultural exploitation of the grassland, the amount finally available to man were calculated.

Indirectly the fauna has catalytic effects on other organisms which are probably much more important: the feeding of animals on fungi eliminates senescent growths, effects the dispersal of spores and overcomes 'stasis', and their fæces provide food sources for other organisms. All such activities increase the rate of energy-flow which ultimately determines the soil fertility.

AGRICULTURAL HISTORY

THE joint winter conference of the Agricultural History Society and the Association of Agriculture was held on December 3, at the Institute of Education, University of London, under the chairmanship of Sir Keith Murray. Before lunch, Mr. Michael Havinden, research assistant, Museum of English Rural Life, read a paper on "Agricultural Progress in Open Field Oxfordshire". Modern research has suggested that the open field system was more flexible than was formerly believed. Mr. Havinden's researches among college documents and seventeenth-century Oxfordshire farmers' inventories has confirmed this still further. He is convinced that the introduction of improved rotations by agreement among the tenants or imposed by manorial lords was a major factor in delaying enclosure in Oxfordshire and possibly elsewhere. The improvement was mainly towards the introduction of fodder crops, the growing of more peas and beans and vetches, and the new legumes clover, sainfoin and lucern as well as some rye grass. In places a group of strips was enclosed by agreement and these crops were grown. He described the mechanism of this process very definitely. In other places fodder was grown and consumed by hitching the grazing animal on the strip. It has, of course, for long been known that sainfoin was grown on the chalk escarpment in the seventeenth century, but only vaguely. Mr. Havinden's researches have revealed places where this and other fodder crops were actually grown in the open fields, and he has thus made specific what was formerly only a general impression derived from remarks in the didactic treatises and propagandist literature of the time.

In the afternoon Mr. John Saville, senior lecturer in economic history, University of Hull, discussed "Public Opinion and Agricultural Depression, 1880–1900". He showed how the current difficulties of the landed interest had led reformers to demand the restoration of a peasant proprietary without any very clear perception of the methods by which the plan could be put into effect. Despite some ameliorative legislation, giving the farm worker the vote, the setting up of parish councils, some small-holding acts, etc., the ideas were in the main quite ineffective. These measures had been supported by liberal reformers in the first place, but afterwards received the backing of the great landlords, Henry Chaplin for example. In spite of that, somewhat less than 1,000 acres of small holdings were created before 1914.

The programme was closed by the showing of a film made by Imperial Chemical Industries in 1942, "The Harvest Shall Come", which is a moving history of the wretched conditions of employment in agriculture before 1914, the comparative prosperity of the workers during the two Wars, and their submersion in poverty in the interval between them, conditions that will never again be imposed.

PROGRESS IN BRITISH BROADCASTING

THE annual report and statement of accounts of the British Broadcasting Corporation for the year ended March 31, 1960, comprises a general review of the year, the reports of the Broadcasting Councils for Scotland and for Wales, chapters on programme output, regional broadcasting, audience research, external broadcasting, engineering, staff and contractual matters, publications and finance, together with a series of appendixes and tables[*]. Matter of scientific interest is contained mainly in the general review and in that on engineering. The general review notes that plans are ready for substantial advances in sound broadcasting, which shows every sign of maintaining a hold on the public in its own right and as a service complementary to that of television. In the overseas and international spheres, further developments and possibilities lie ahead for the Corporation, especially in the field of television, and, generally, the Corporation considers that it has gone a considerable way to map out the courses that it should follow and the programme of development that will be needed during the next five to ten years.

The Corporation welcomes the Government's decision that during 1961–62 the full net proceeds of the licence revenue, apart from the £1 excise duty, should be devoted to broadcasting. However, the retention by the Treasury of 5 per cent of this revenue in the current financial year has necessitated the slowing down or postponement beyond 1960–62 of some projects which the Corporation regards as highly desirable, and which it wishes to complete at the earliest possible date. During the year the number of householders with combined licences for sound and television rose from 9,255,422 to 10,469,753, and that of those with licences for sound only decreased from 5,480,991 to 4,535,258. About 97 per cent of the population of the United Kingdom are now within range of the VHF sound broadcasting network, and it is estimated that rather more than one household in five has a VHF receiver. In sound, as in television, the Corporation is planning to provide or improve coverage in certain difficult areas by building low-power satellite stations, and schemes have also been prepared both for a further extension of coverage and also for introducing a system of local broadcasting on VHF. Audience research indicated that adult viewers with a choice of BBC and ITV were devoting some 37 per cent of their evening viewing time to BBC programmes in the last quarter of the year, compared with 32 per cent in the first quarter.

Experience gained during the past eleven years suggests that the restriction on broadcasting imposed by Section 63 of the Representation of the People Act, 1949, is now out of date, and the report expresses the hope that action will be taken to amend the Act accordingly. In science broadcasting, Prof. Medawar's Reith Lectures took an outstanding place, and upwards of 150 leading scientists took part in science programmes in sound radio during the year, while in television "Eye on Research", in which scientists in many fields demonstrate their equipment and research techniques and explain the work that they are doing, was the main continuing contribution. From time to time, however, the full resources of television are deployed on some major scientific theme, but the series of televised scientific demonstrations given by Sir Lawrence Bragg in the main lecture theatre of the Royal Institution were also highly appreciated by viewers. Preparations went forward throughout the year for the increase in output of the school television service to take place in the 1960–61 school year, and the scope of the service will also be extended to cover some of the special needs of primary schools and of the sixth forms of grammar schools.

Referring to regional broadcasting, the report expresses the view that if full advantage is taken of the opportunities for development, in adjustment to the changing needs of the time, regional activities in sound will form an enduring part of the overall pattern of the Corporation's broadcasting; but, while sharing fully the desire of the Broadcasting Council for Wales for an allocation of frequencies which would permit a separate television transmitter for South Wales, the Corporation has been unable to take the necessary steps because of the insufficiency of channels available. At present the Corporation's television service covers 98·8 per cent of the population of the United Kingdom, but the technical problems in bringing this to 100 per cent are formidable and are discussed in some detail in a special section of the review dealing with future tasks. The first of these is seen as the extension and improvement of transmitter coverage in areas where reception, whether of sound or television programmes, is unsatisfactory or non-existent. For television the only frequencies that could be readily applied for this purpose are the as yet uncommitted channels in Band III, and if the Government decides that these should be used for an additional television service, the Corporation wishes to provide the additional service. Apart from giving viewers a genuine alternative service, this second service would enable the Corporation to increase the number of serious, cultural and informative programmes, to cater more fully for regional needs, to extend educational broadcasts, and to provide more opportunity for experimental programmes. The Corporation believes that a move into Bands IV and V, which is an essential condition for a change in television standards, can be made successfully only if the public has the incentive of one or more new programmes in these bands. Given the necessary frequencies and finance, the Corporation would be prepared to start a new service in these bands and also if the Government so decided to start a service of colour television in Bands I or III, taking advantage of the experience it has already acquired and of the many experimental transmissions it has made in colour using the present 405-line standard. The Corporation claims that it could start a second television service in Band IV if it were granted the full proceeds of the present £4 licence, and that full development of the Corporation's services in sound and television, including a new television service in Bands IV and V and of colour, would call for a combined licence at about £5.

---

[*] Annual Report and Accounts of the British Broadcasting Corporation, 1959–60. Pp. 175+8 plates. (Cmnd. 1174.) (London: H.M. Stationery Office, 1960.) 8*s.* net.

Under engineering research and development, the report notes that a comprehensive report has been prepared for publication on a series of experimental transmissions in Band V which included a comparison of the existing British 405-line standard and the Continental standard of 625-lines. The regular experimental stereophonic transmissions, commenced in 1958, have been continued, and the Corporation is investigating possible systems of broadcasting both stereophonic channels from a single VHF transmitter in such a way that monophonic reception is not impaired. Research continued into various aspects of videotape recording as well as investigation of the propagation properties of the ionosphere, for purposes of day-to-day operation of the Corporation's short-wave services, and considerable effort has been directed to the design of equipment using transistors instead of valves, although in broadcasting, and particularly in television, it is difficult to obtain the same high standard of performance from transistors as can be obtained from valves. Nevertheless, in almost all new portable or mobile audio-frequency equipment, and also in fixed equipment designed to operate independently of the public mains supply without large and costly batteries, it is possible and advantageous to use transistors.

While there is a marked potential audience for the Corporation's external broadcasts, to which the development of transistor receivers, cheap and easy to run, has made an important contribution, especially for medium-wave transmissions, Communist China has now displaced the BBC as the third largest external broadcaster. The services have been extended in certain directions, but rising costs and the stringent limitation of grants by the Government have offset the expansions by reductions elsewhere, and the report stresses the challenge which faces external broadcasting from the United Kingdom. In meeting it, the Corporation's international reputation for reliability and independence, its long experience and its established position as a source of programmes regularly heard and re-broadcast throughout the world are solid advantages, but they require ample technical support, particularly by way of higher-powered transmitting stations in the United Kingdom and more relay stations overseas. When this is forthcoming, the BBC will be able to take greater advantage of the many opportunities for presenting Britain to the world through this medium.

SCIENTIFIC RESEARCH IN NEW ZEALAND

THE report of the Department of Scientific and Industrial Research, New Zealand, for the year ended March 31, 1960, shows gross expenditure of £1,812,000, and staff at April 1, 1960, totalling 1,121, including 401 professional, compared with 1,067 and 390, respectively, in the previous year*. It includes the Minister's statement, the report of the Council for Scientific and Industrial Research, the Secretary's report, notes on the work of the several branches and divisions as well as of the incorporated research associations and on grant-aided research in other institutions, and also lists of publications. The second annual report of the Ross Dependency Research Committee is appended, to which also is attached a list of publications. A survey of the work of the Department made by the Council during the past two years led to the conclusion that in most branches the balance was held between *ad hoc* and long-term basic research, though in a few units basic research could with advantage be strengthened. Over the past decade the number of scientific staff employed by the Department has remained virtually static and there is virtually no scope for readjustments to meet the demands of new developments in nuclear science, oceanography, geothermal or Antarctic activities. Limitations of staff and finance debar the Department from exploiting fully the scientific opportunities to assist primary and manufacturing industry, and the Council estimates that full implementation of the present programme of work requires an increase of 40–50 staff per annum and of expenditure from £1,812,000 in 1959–60 to £2,090,000 in 1960–61, £2,133,000 in 1962–63 and £2,265,000 in 1964–65, assuming that costs and salary scales remain at the 1959 level. Provision of £200,000 per annum for buildings over the next five years is also recommended, apart from the cost of some major items of equipment such as a small nuclear reactor and electronic computer. Establishment of a National Research Organization as an independent organization responsible for the main research functions of Government is recommended as likely to lead to greater efficiency, better co-ordination in existing research programmes and greater flexibility in meeting future needs, and finally the urgent need for a thorough revision of professional salaries is emphasized.

Since 1949–50 the expenditure of the Department has risen from £959,000 to £1,658,000 in 1958–59, and was only 0·146 per cent of the gross national product, compared with 0·173 per cent, and the professional staff numbered 383 compared with 363. Research grants to universities, research institutions, etc., in 1959–60 totalled £172,272, but the only branches of the Department in which expenditure exceeded £100,000 were the Dominion Laboratory (£194,180), Dominion Physical Laboratory (£199,203), Geological Survey (£102,750), Geophysics Division (£111,206), Grasslands Division (£108,078) and Soil Bureau (£105,512).

The Secretary's report refers briefly to some of the research work of the year. An extensive programme of tests on the durability of paints showed that poor workmanship and inferior quality of paint were the prime causes of poor durability, with excessive weathering of priming coats and the dip-treatment methods of timber preservation as contributory factors. More careful attention to surface preparation is required when using synthetic finishes. Use of sawdust or shavings from arsenic-treated timber in smoke curing has been shown to constitute a toxicity hazard through deposition of arsenic on the food. The analysis of steel and reinforced-concrete frame structures is being continued, and the use of an analogue computer offers a big advance on the traditional technique of applying a static seismic coefficient. The computer is being modified to allow for multi-storey yield.

---

* New Zealand. Report of the Department of Scientific and Industrial Research for the year ended 31 March, 1960. Pp. 128. (H. 34.) (Wellington: Government Printer, 1960.) 4s. 6d.

A major addition to the equipment used in the auroral programme has been the auroral radar set up at Arrival Heights close to Scott Base, and the unmanned automatic observatory operating for a year near Becks in Central Otago has demonstrated the superiority of conditions there for all aspects of the optical work. The Geophysical Observatory has made a special investigation of the New Zealand ionospheric data to meet requests made by the Post and Telegraph Department, and a detailed magnetic survey was made on the aircraft compass-swinging site at Wellington Airport; this was to ensure that the area was free from magnetic effects due to buried ferro-magnetic materials that might affect aircraft compasses. Considerable attention has been directed to modern map-preparation techniques and procedures in cartography, and a major activity of the Antarctic programme has been the continuation of the geological and topographical survey of the Ross Dependency begun by parties from the trans-Antarctic Expedition. A major step forward in pollen research in New Zealand will be the publication this year of a *Geological Survey Palaeontological Bulletin* recording the important results of a new phase of the work—the successful extraction of pollen from marine sedimentary rocks.

In the past year the New Zealand benthic survey has concentrated on the west coast of the North Island and the western approaches to Cook Strait, and the survey is also building up collections of marine bottom fauna from which the common New Zealand species, and many of the rarer ones can be identified and described. Work on the design of a gas-pressure alarm system in telephone cables led to a method of calculating the required shapes of the pressure waves for a cable of given permeability to the gas for any size of puncture. At the Dominion Physical Laboratory the internodal cell of the alga *Nitella* is being used for an investigation of cell wall growth. Work has been carried out on the growth of *Pithomyces chartarum* on various synthetic media, and on the influence of different factors on the production of spores, while the fatty acid composition of this and related species has been determined and a systematic investigation made of the anti-fungal substances in sweet vernal and red clover.

Much of the development programme at the Keikohe sub-station of the Grasslands Division has been concerned with the typical heavy clay 'gumland', which is very acid, extremely low in plant foods and has a typical 'gumland' cover of stunted manuka and rushes. Heavy dressings of lime, phosphate and potash at the time of sowing gave spectacular results. Work on the South Island tussock grasslands has revealed two undescribed and widespread grassland associations of botanical and economic importance. Two high-yielding varieties of potato have been bred which appear to combine resistance to wind and drought with resistance to late blight, and use of systemic insecticides has opened up possibilities of producing better seed potatoes in areas such as Lincoln, where aphid numbers are high for only short periods. By use of stickers and cultures with a high bacterial count, nodule bacteria have been held on lucerne seed in a viable condition for at least four weeks, while work on scale insects on apples indicates that shelter belts of *Pinus radiata* are the cause of the trouble. Factors governing the need for potash top-dressing on New Zealand soils are also being studied as well as pruning systems for apples, the storage of apples in controlled atmospheres, the control of *Verticillium* wilt of tobacco and the general ecology of rabbits, while a survey at Lake Monk, Southern Fiordland, has contributed towards the understanding of the relations which have arisen between introduced animals and native forests.

THE DELHI ENGINEERING COLLEGE TRUST

At a meeting of the sponsors of the Delhi Engineering College Trust, held at Bowater House on November 16, the chairman, Sir William McFadzean, president of the Federation of British Industries, reviewed progress in the setting up of the College, in which H.M. Government, the Government of India and British industry are working together with the aim of establishing an outstanding institution for technical education.

Since January 1959, when Prince Philip laid the foundation stone of the College at Delhi, the Government of India has completed the administrative organization and has set up a governing body of which the chairman is Prof. M. S. Thacker, Permanent Secretary of the Indian Ministry of Scientific Research and Cultural Affairs. All preparations are in hand for the opening of the College during July 1961, on the magnificent Haus Kas site near Delhi.

The United Kingdom Government has undertaken to provide ten British professors for the College, who will advise the Indian professorial staff during the first five years. Four professors are already at Delhi, and three more are to be appointed this year.

Sir William also reported the success of the appeal to British industry for subscriptions to provide equipment for the College. The target figure of a quarter of a million pounds had been exceeded, thanks to 115 companies which had contributed over the past year. Over the next three years, as the buildings of the College are completed, the equipment for the successive stages of the five-year course is to be purchased on behalf of the Trust by the Crown Agents for Oversea Governments and Administrations.

Sir William then outlined the desirability, after the College was established, of offering continuing academic and practical support for it from the United Kingdom Government, British industry, and British universities and colleges. This was a matter to which the sponsors would be invited to give further attention when the time was ripe. In the meantime, the progress that was being made in all preparations for the opening of the College held out good promise for its future as a centre of advanced education in engineering in India.

Sir Eric Coates, chairman of the Executive Committee of the Trust, described how the most modern equipment for the College was being selected, in accordance with the advice of an academic working party under the chairmanship of Prof. S. R. Sparkes, of the Imperial College of Science and Technology; and how other aspects of the project were developing in accordance with the programme of the Indian Government.

Sir Willis Jackson, as chairman of the Technical Sub-Committee of the Trust, referred to the difficulties at the present time of finding the right calibre of man for professorial posts. He emphasized the need for further help by British industry, perhaps by endowing chairs at the College, and also by facilitating the secondment of experts in specialist fields of technology for short periods to assist in the conduct of postgraduate courses and in stimulating research.

Sir Algernon Rombold, Deputy Under-Secretary of State, Commonwealth Relations Office, said that satisfaction at the response to the sponsors' appeal would be widely shared, and that the project was an outstanding example of co-operation between the Governments of India and the United Kingdom and British industry. He endorsed the hope that a recognized system of secondment by industry and universities would be developed to meet the growing need for experts for overseas service.

Sir Alexander Fleck said that the vigour of the work of the Trust's officers showed that the special problems presented by any tripartite project of this nature were being solved in a satisfactory way. He believed that the continued support of British industry would be readily forthcoming for the project on the lines which Sir William McFadzean had sketched out. This would be true both in the immediate future and over the years as the project developed.

Among the other sponsors present were Sir Hugh Beaver, Sir Leslie Gamage, Mr. S. E. Goodall, Sir Kenneth Hague, Sir Harry Jephcott, Prof. Sutton Pippard and Mr. Whitney Straight. Other sponsors who were unable to attend were represented.

THE ROBERTSON CREEK SPAWNING CHANNEL

MUCH of a recent issue of the *Canadian Fish Culturist* (No. 27, 1960) is given up to accounts by K. C. Lucas and D. Mackinnon of a man-made spawning channel which has just been built by the Fish Culture Development Branch of the Department of Fisheries of Canada in Robertson Creek. This is a secondary outlet of Great Central Lake, which lies near Port Alberni on Vancouver Island, British Columbia.

The design of this new artificial spawning channel is based on the experience gained in the construction and operation of an artificial spawning channel on Jones Creek, near Hope, British Columbia, which was made in 1954. The Jones Creek channel was constructed to save the salmon stocks in a stream threatened by the diversion of the flow because of hydro-electric development, but the Robertson Creek channel is the first such channel to be built primarily as a fisheries development project. Robertson Creek is an exceptionally favourable area for such a project, because works for the complete control of flows already existed, no provision for flood-flows was necessary, silting of the spawning beds by the incoming water seemed unlikely, the temperature of the stream remained moderate and the area was readily accessible.

The total length of Robertson Creek is 4,200 ft., and 2,550 ft. have been developed as a spawning channel. The gradient of the natural stream bed was greater than that needed for the spawning channel, so four drop-structures have been provided to localize the unwanted drop. Near the head of the spawning channel and a short distance below Great Central Lake is a downstream migrant diversion structure, which allows migrants passing out of Great Central Lake to be diverted into a flume which runs alongside the spawning channel to enter the latter just below drop structure 3. If it were found necessary in the future, this diversion flume could be extended downstream so as to bypass the lower spawning area. The first three drop-structures downstream from the diversion structure are similar in design and are relatively simple structures. Inclined plane traps are provided at each so that downstream migrants can be counted, and each incorporates a pool and weir-type fishway to provide for the upstream movements of adults if desired The lowermost drop-structure (4) is larger and more complex, because it incorporates a fish holding and collection system, and there is an observation chamber built into the side of the fishway.

A number of rearing ponds have been built at one side of the channel near its upper end, and these have been specially designed to allow maximum flexibility. Another additional structure is of particular interest; this is an experimental test-flume, approximately 150 ft. long and 30 ft. wide, which lies in the channel a short distance below drop structure 3. Plans were made to construct this flume before it was decided to make the channel, and the Fisheries Research Board of Canada has contributed to its cost. This flume will be used for tests of fry and smolt guiding devices and for fundamental work on the physiology of adult salmon.

Previous work on the survival of Pacific salmon eggs and alevins has shown that the percentage survival varies widely, but is usually low (less than 10 per cent). The results of the first transplant of pink salmon eggs in the Robertson Creek spawning channel are therefore particularly encouraging More than one and a half million pink salmon were planted, at the eyed stage, during the latter half of November and the first days of December 1959. The first fry was trapped on March 15, 1960, but nearly all the fry migrated during the first three weeks of April and, when the last batch recorded migrated, during the night of April 21–22, the total represented roughly 95 per cent of the eyed eggs planted.

This artificial spawning channel is clearly a very important site for experimental investigations of many aspects of the biology of various stages in the life-history of Pacific salmon. Judged as a piece of experimental equipment, it is not cheap. To date, more than £81,000 has been spent on the channel. the experimental flume and the small field camp which has been built near the lower end of the channel It is becoming increasingly clear, however, that many problems of salmon biology cannot be solved unless adequate experimental facilities can be provided. and there is good reason to suppose, therefore, that this outlay will prove to be money well spent.

AN ATOMIC BEAM SPECTROPHOTOMETER

By G. R. ISAAK*

Central Research Laboratories, Imperial Chemical Industries of Australia and New Zealand, Ltd., Melbourne

THIS article describes an optical spectrometer of extremely high resolution which has been developed in these Laboratories during the past two years. It is similar in principle to recently described X-ray spectrometers based on the Mossbauer effect[1], but differs in that it is concerned with wave-lengths in (and near) the visible region of the spectrum.

The present instrument is based on the principle of scanning the spectral line under study by measuring the variation of intensity of transmitted light as the absorbing line is made to traverse the width of the emission line under investigation. Extremely narrow spectral lines of nearly natural line-width are obtained by using a highly collimated atomic beam[2,3] emitting, absorbing or scattering light at right angles (or nearly so) to the direction of motion of the atoms, thus reducing Doppler broadening.

This narrow spectral line can then be used (by the Zeeman, Doppler, Stark or modulation effects[4]) to scan the spectrum under study, and, from the variation of transmission (or resonant scattering) versus displacement, the wave-length of the centroid of the spectrum and its profile can be deduced.

The range of wave-lengths which can be scanned is restricted to the immediate vicinity of the resonance lines of the atoms composing the beam, although it may be possible to examine other than resonance lines by populating excited levels of atoms by resonance radiation or electron bombardment. In practice the Zeeman scan can cover a range of the order of ± 0·1 Å. for magnetic fields of 10,000 gauss. The range is usually very much smaller for scans relying on the Doppler shift, the Stark splitting or the modulation effect.

The resolution of the method is determined by the width of the spectral line used. If the resolution R is defined in terms of a criterion analogous to the Rayleigh criterion[4] we have $R = \lambda/\Delta\lambda$, where λ is the wave-length and $\Delta\lambda$ is the wave-length change of a perfectly monochromatic incident light-beam which will result in a 19 per cent change in absorption. Then the resolution R can reach 10^8 or more by collimating the atomic beam sufficiently to reduce the Doppler broadening, and it is ultimately limited by the natural line-width to a value $R = \lambda/\Delta\lambda = 4\cdot 1\ c/\lambda\gamma$ using the Lorentzian line shape, where c is the velocity of light and γ is the total transition probability per unit time[5]. Thus for mercury, ideally for a single even isotope of mercury, for example, mercury-198, we would expect[6] $R_{\text{max.}} = 5 \times 10^8$ for the 2536·5 Å. spectral line.

Two sealed glass atomic beam units (Fig. 1) were constructed to demonstrate the high resolution attainable with the above method. Because of its convenience, sodium was used as a working substance although its D lines have a complex structure. A low pressure was maintained by a small titanium pump[7]. An electric oven was used to heat the sodium to 300° C. and two glass slits of dimensions 2 × 18 mm. spaced 10 cm. apart collimated the atomic beam, which entered an observation chamber and condensed on a surface cooled with liquid nitrogen. To avoid appreciable Zeeman splitting of the spectral lines by stray magnetic fields in the vicinity of the observation chamber, the pumping magnets were removed during measurements. A pressure of 10^{-6} mm. mercury or less could be maintained for several hours without the operation of the pump by using sodium purified by multiple distillations, and baking the glass unit for many hours before sealing off.

Two such units were arranged as shown in Fig. 2. The sodium vapour lamp L illuminated the atomic beam E of sodium (the emitter) shown in plan. A second atomic beam unit A, with the atoms moving parallel to those of the emitter E, could be used as a resonant absorber. Of the light scattered at right angles to the direction of the atomic beam E, a beam subtending a very small solid angle served as a source of nearly monochromatic light of known line profile. The shape of this spectral line was examined by measuring the intensity of the light transmitted with the photomultiplier $D1$, as the absorber spectral line was moved across the emission line. The outputs of photomultiplier $D1$ and comparison photomultiplier $D2$, looking at the emitter only, were amplified in a difference amplifier and recorded on an XY recorder.

In the first experiment the practicability of Zeeman scanning was investigated by placing the absorber A in a magnetic field generated by a set of Helmholtz coils.

Light resonantly scattered by the emitter E passed through the absorber A parallel to the magnetic field

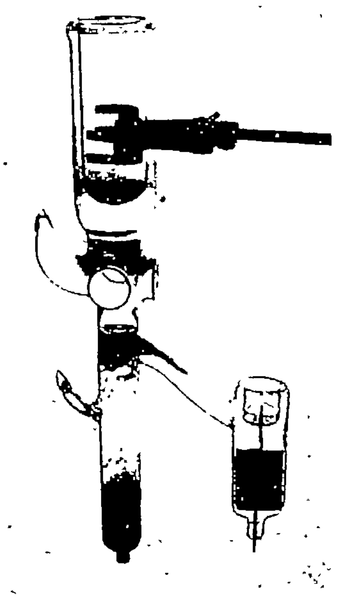

Fig. 1. A sodium atomic beam unit

* Present address: Physics Department, University of Birmingham.

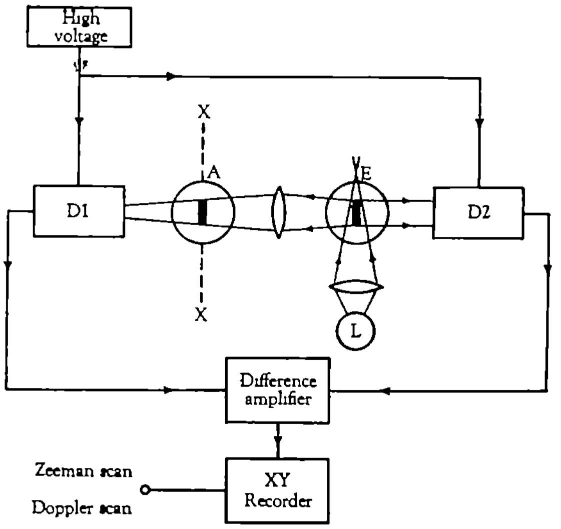

Fig. 2. Arrangement of apparatus for demonstration of high resolution of the method

and was detected by the magnetically screened photomultiplier $D1$ and recorded by the XY recorder as a function of the magnetic field by driving the X-axis with a voltage signal derived from the current through the Helmholtz coils. Electron-spin resonance in a small sample of $\alpha\alpha'$diphenyl picryl hydrazyl placed in a position normally occupied by the atomic beam was used to calibrate the linear magnetic field scale. Fig. 3 shows a typical Zeeman scan having a full width at half height of 67 gauss. This value is only slightly larger than the value calculated on the assumption that each hyperfine structure component of the emission and absorption lines of sodium has a fractional width of $3{\cdot}8 \times 10^{-8}$ (natural line-width $2{\cdot}1 \times 10^{-8}$ and residual Doppler-width $3{\cdot}1 \times 10^{-8}$), and each hyperfine structure component of the absorption line is split up in the weak magnetic field into a multiplet with an effective magnetogyric ratio of 0·55 Bohr magneton for the six components.

In a second experiment the feasibility of Doppler scanning was studied by slowly rotating the absorber atomic beam A about an axis X (Fig. 2) and recording the transmission as a function of inclination θ of one beam with respect to the other.

By rotating the absorber atomic beam through an angle θ the absorption line is displaced by an amount $\Delta\lambda = \lambda\bar{v}/c \sin\theta = \lambda\bar{v}/c\ \theta$ for small θ, where $\bar{v}$ is the mean velocity of the atoms in the beam. Consequently, a measurement of the transmission in the range $\pm\theta$ corresponds to a measurement of the overlap of the emission and absorption lines as the wave-length difference varies from $-\Delta\lambda$ to $+\Delta\lambda$.

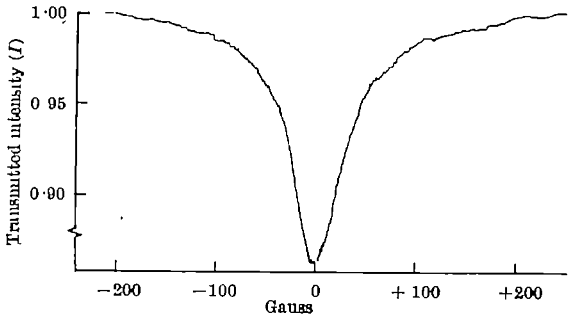

Fig. 3. Zeeman scan showing variation of transmitted intensity I with magnetic field applied to absorber A

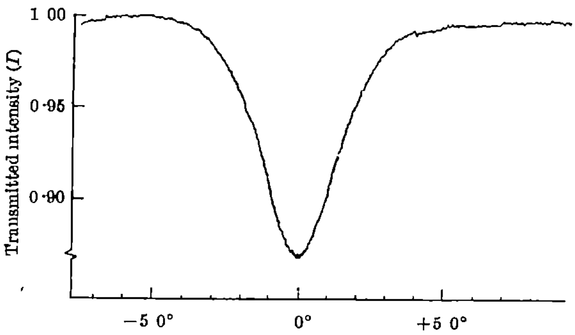

Fig. 4. Doppler scan showing variation of transmitted intensity I with inclination θ of absorber A with respect to emitter E; angular rotation through 1° corresponds to a wave-length change of 3×10^{-4} Å.

Unfortunately such a rotation produces a broadening and asymmetry[8] of the spectral line in addition to the Doppler displacement.

Fig. 4 shows such a transmission profile with a full width of $\theta = 3{\cdot}0°$. Assuming a mean atomic beam velocity[9] of 870 m.sec.$^{-1}$, this corresponds to a fractional width of $\Delta\lambda/\lambda = 15 \times 10^{-8}$.

This value exceeds slightly a theoretical estimation, taking into account the natural line-width, the residual Doppler broadening, the inclination broadening and the broadening resulting from the overlap of the hyperfine structure components of the $D1$ and $D2$ lines of sodium.

From these results it was deduced that the components of the sodium D lines had widths of approximately $\Delta\lambda/\lambda = 4 \times 10^{-8}$ corresponding to a resolution of the order of 10^{8}, but because of the overlap of the hyperfine structure components the resolution was reduced by a factor of 2.

We can conclude that the above method can, in rather special circumstances, produce very high resolutions and can be used to study spectral line displacements, spectral line profiles and integrated areas under a spectral line. The resolution is highest and the interpretation of the results is simplest if the atoms in the beam have a simple spectral line, that is, have no nuclear spin and are identical.

Among the obvious applications is the study of isotope shifts. A particularly attractive case would be the study of isotope shifts of mercury using one beam of a separated isotope of zero nuclear spin, for example, mercury-198.

An atomic beam of sodium is being used as a high-resolution spectroheliograph for the study of the profiles of the Fraunhofer absorption lines.

I wish to thank Mr. R. A. Dewar and Dr. R. L. Martin for their interest and the Directors of Imperial Chemical Industries of Australia and New Zealand, Ltd., for permission to publish this material.

INFLUENCE OF MOLECULAR STRUCTURE ON THE LIQUID/LIQUID EXTRACTION OF THE CHLORO-COMPLEXES OF GALLIUM AND INDIUM WITH ALIPHATIC ETHERS

By Dr. R. R. BROOKS and P. J. LLOYD

Department of Chemistry, University of Cape Town

THE determination of elements of low abundance in geological materials is of considerable interest in geochemistry, and very sensitive methods have been developed in recent years for the estimation of these trace elements Such techniques include neutron activation[1] and recent work on the combination of ion-exchange enrichment and spectrochemical analysis[2–5]. There is clearly a place for solvent extraction methods in the general scheme of analysis of elements of very low abundance, and this particular field seems to have been neglected in recent years.

An investigation has therefore been made into the extraction of gallium and indium (both elements of geochemical interest) from solutions of different concentrations of hydrochloric acid into a series of seven aliphatic ethers in an attempt to study more fully the factors involved in the extraction of these elements. (For reviews of general extraction procedures, see Irving[6], Martin and Holt[7] and Kitahara[8]).

Both indium and gallium are able to form ion-association complexes in the presence of hydrochloric acid, and in its very simplest form the mechanism is probably :

$$In^{3+} + 4\,Cl^- \rightleftharpoons InCl_4^- \qquad (1)$$

$$InCl_4^- + H^+ \rightleftharpoons H^+, InCl_4^- \qquad (2)$$

According to Bjerrum[9], the stability constant of the ion-pair formation (K) is dependent on the absolute temperature (t), the distance apart of the charge centres (d) and the dielectric constant of the solvent (e). In a simplified form the Bjerrum equation may be represented as follows :

$$K = \frac{C}{d.e.t.} \qquad (3)$$

where C is another constant.

At constant temperature it is obvious that K will depend on d and e, and part of the purpose of the present investigation was to attempt to establish the relative importance of these two factors.

If ion-association complexes only of the type shown in equation (2) were formed, then presumably the distance between the charge centres would always be constant and the extent of extraction into the ethereal phase would, at constant temperature, depend only on the dielectric constant of the solvent. However, oxonium solvents can play a special part in ion-association systems, since the basic character of the oxygen atom enables the solvent molecule to be incorporated in the co-ordination sphere of the metal[10]. We may therefore expect to have association complexes formed in the following manner :

$$In^{3+} + 6\,R_2O \rightleftharpoons In(R_2O)_6^{3+} \qquad (4)$$

$$In(R_2O)_6^{3+} + 4\,Cl^- \rightleftharpoons In(R_2O)_2Cl_4^- + 4\,R_2O \qquad (5)$$

$$In(R_2O)_2Cl_4^- + H^+ \rightleftharpoons H^+, In(R_2O)_2Cl_4^- \qquad (6)$$

In this case it would appear that steric effects should play an appreciable part in determining the value of the stability constant of the complex, since they will to a large extent determine the value of the charge distance d. A study of the extractability of gallium and indium into a series of homologous ethers should clearly furnish valuable data about which mechanism is operative in the extraction of these metals, provided the dielectric constants of the solvents are also known.

Experimental Procedure

A stock solution was prepared containing 0·02 mgm. of indium and the same quantity of gallium per ml. 1-ml. aliquots of this solution were transferred to a set of 50-ml. test-tubes, and varying amounts of hydrochloric acid and water were added to each so that the final volume was 5 ml. and the final concentrations of hydrochloric acid were : N, 2 N, 3 N, 4 N, 6 N and 8 N, respectively. Five ml. of an aliphatic ether (pre-equilibrated with the appropriate strength of hydrochloric acid) were then added to each test-tube and the contents shaken for 3 min. The phases were then separated and transferred to 50-ml. porcelain basins. Twenty mgm. of sodium chloride were then added as a matrix and the samples were taken to dryness. The residues were then loaded into graphite electrodes and the indium and gallium determined spectrochemically, using the magnesium impurity in the sodium chloride as internal standard. The spectra (2750–4680 Å.) were recorded on Kodak 103-0 blue-sensitive plates. The spectral intensities

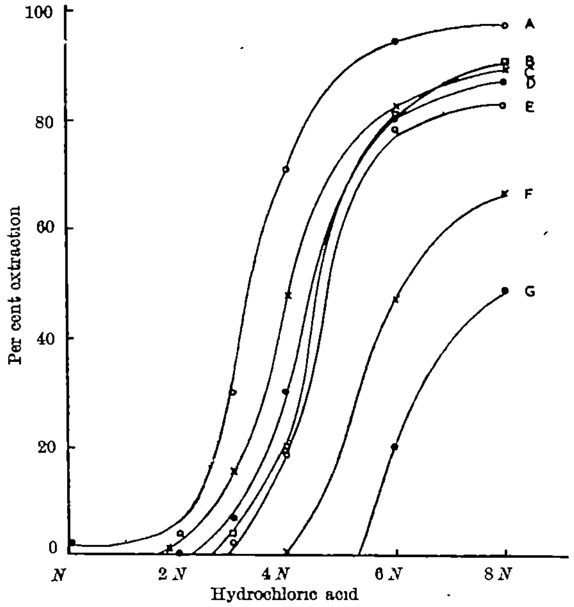

Fig. 1. Percentage extraction of gallium into aliphatic ethers from a range of concentrations of hydrochloric acid. A, ethyl ether ; B, methyl-hexyl ether ; C, ethyl-hexyl ether ; D, methyl-butyl ether ; E, *iso*propyl ether ; F, butyl ether ; G, amyl ether

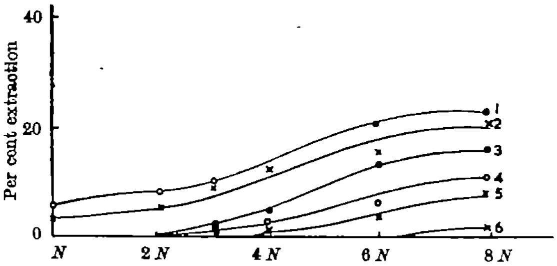

Fig. 2. Percentage extraction of indium into aliphatic ethers from a range of concentrations of hydrochloric acid. 1, ethyl ether; 2, methyl-hexyl ether; 3, ethyl-hexyl ether; 4, methyl-butyl ether; 5, *iso*propyl ether; 6, butyl ether

were measured and the percentage extraction hence determined.

The experiments were carried out on the following solvents: ethyl ether, *iso*propyl ether, butyl ether, amyl ether, methyl-butyl ether, ethyl-hexyl ether and methyl-hexyl ether. In every case the solvent was purified by distillation over sodium after removal of peroxides.

In Fig. 1 the percentage extraction of gallium is shown as a function of concentrations of hydrochloric acid for each of the seven ethers. The corresponding results for indium are shown in Fig. 2.

The dielectric constant for each ether was measured by the conventional condenser-resonance method[11], in which the sample is placed in a special cell between two silver electrodes and forms the dielectric of a condenser. A variable condenser is tuned to resonance with this system and the dielectric constants hence determined. These results are shown in Table 1.

Table 1. DIELECTRIC CONSTANTS OF ALIPHATIC ETHERS AT 20° C

Solvent	Dielectric constant
Ethyl ether	4·33
Methyl-butyl ether	4·20
Ethyl-hexyl ether	4·05
*Iso*propyl ether	4·04
Methyl-hexyl ether	3·90
Butyl ether	3·08
Amyl ether	2·82

An examination of Figs. 1 and 2 shows that, far from increasing with decreasing dielectric constants, the extractability of the chloro-complexes of indium and gallium actually decreases, and indeed at 4 *N* hydrochloric acid a plot of percentage extraction of gallium as a function of dielectric constant shows an approximately linear relationship of positive slope. Since the influence of dielectric constant appears to be slight, then, on the basis of Bjerrum's theory, the effect of the solvent co-ordination mechanism on the extraction of the complexes must be important, because this is the greatest factor which determines the distance apart of the charge centres. This co-ordination involves the question of steric hindrance where the size of the solvent molecule will obviously affect the factor d in the Bjerrum equation.

A study of the curves for gallium reveals a rather surprising fact (which is also obvious to lesser degree in Fig. 2), and this is the apparently greater efficiency of the asymmetric ethers for extracting the complexes compared with the symmetric compounds. In terms of extracting power, the three asymmetric ethers appear to be intermediate between ethyl and *iso*propyl ether, whereas steric considerations would tend to indicate an extraction potential certainly inferior to that of butyl ether. The symmetric ethers show a regular decrease in extracting power with increasing molecular weight, and the pattern is identical for indium and gallium.

This anomalous behaviour of the asymmetric ethers poses an interesting problem. A possible explanation may be that the greater dipole moments of these ethers play an important part in determining the extent to which they are able to enter the co-ordination sphere of the metal. It is considered that these higher dipole moments may lead to an increased electron density at the donor oxygen atom due to electrostatic forces within the molecule and hence increase the tendency of the solvent to co-ordinate with the appropriate metal.

FATTY ACID PATTERN IN THE AORTA LIPIDS OF COCKERELS IN THE INITIAL STAGE OF CHOLESTEROL- OR STILBŒSTROL-INDUCED ATHEROSCLEROSIS

By DR. ROLF BLOMSTRAND and DR. SØREN CHRISTENSEN

Swedish Medical Research Council Unit for Biochemical Research on Atherosclerosis, University of Lund, Sweden, and Department of Physiology, University of Aarhus, Denmark

IN the chicken, either the addition of cholesterol to the diet or the implantation of stilbœstrol pellets leads to a striking increase in blood lipids followed by the development of diffuse lipid infiltration of the inner parts of the aortic wall on which atheromata formation[1] is later superimposed. The mechanism of the atheromatous changes is poorly understood, although it is generally believed to be closely associated with cholesterol metabolism, which in turn is related to fatty acid metabolism[2]. In order to elucidate the relationship between fatty acid metabolism and the development of atheromatous changes a study was undertaken of the fatty acid composition of the cholesterol esters, triglycerides and phospho-

Table 1. THE FATTY ACID COMPOSITION OF THE LIPIDS OF AN INTIMA-MEDIA PREPARATION OF THE COCKEREL AORTA

Group *A*, nine normal cockerels; Group *B*, three cockerels fed 1 per cent cholesterol plus 3 per cent peanut oil in the diet; Group *C*, two cockerels fed 1 per cent cholesterol without any oil; Group *D*, two cockerels implanted stilbœstrol pellets subcutaneously (no oil).

The tissues from the animals within the groups were pooled and the total fat extracted. The total lipids were separated into cholesterol esters, triglycerides and phospholipids on silicic acid.

Values are expressed as per cent of total fatty acid methyl ester

lipids of the blood and aorta lipids in cockerels with experimental atherosclerosis.

The present report deals with part of the analyses carried out on the aortic lipids. The findings may be significant regarding the pathogenesis of atherosclerosis, because they indicate changes in the oleic acid metabolism.

The cockerels used were a cross-breed of White Leghorn and New Hampshire, 5 months old at death.

Three groups of three normal cockerels were fed ordinary chick starter mash mixed with grain (1 : 1). The results from these three groups were averaged and are presented as group *A* in Table 1. Three animals (group *B*) were given a supplement to the mash consisting of 1 per cent by weight of cholesterol and 3 per cent peanut oil during 10 weeks before killing. Two animals (group *C*) were given 1 per cent cholesterol *without* any extra oil. Two animals (group *D*) were treated with stilbœstrol. Pellets of diethylstilbœstrol, each containing 10 mgm., were implanted subcutaneously. Eight implantations were performed at intervals of 10 days during a 10-week period. The last implantation was performed 5 days before death.

The aorta (including the brachiocephalic trunks) was dissected free from any visible fat and loose connective tissue. Approximately the inner half of the aortic wall (about 200 mgm. wet weight) consisting of intima and part of the media was isolated for fatty acid analysis.

In two of the aortas from the cholesterol-fed animals (group *B*) non-elevated, white-yellow areas were found in the intima. In one of the aortas from the stilbœstrol-treated animals (group *D*) atheromatous changes were also found.

Cockerels fed cholesterol and 3 per cent peanut oil (group *B*) showed a 270 per cent increase in cholesterol and a 14 per cent increase in phospholipid in the inner one-half of the aortic wall. Cockerels fed cholesterol without oil (group *C*) showed a 50 per cent increase in aorta cholesterol. Animals treated with stilbœstrol (group *D*) showed a 190 per cent increase in cholesterol and a 24 per cent increase in phospholipids of the aorta as compared with normal controls.

The aorta preparations within the three animal groups were pooled, cut into small pieces, and then extracted with ethanol/ether (3 : 1). The combined extracts were evaporated under nitrogen, dried in vacuum and dissolved in light petroleum.

The total lipids were separated on silicic acid into three fractions: cholesterol esters, non-esterified fatty acids plus triglycerides, and phospholipids[3].

The fatty acids of the three fractions were isolated and the methyl esters prepared by treating with diazomethane in ether. The fatty acid composition was determined by gas-liquid chromatography according to James and Martin[4] using a Pye argon chromatograph with an ionization chamber as detector. Because of the complexity of the fatty acid pattern, it was necessary to chromatograph the mixed methyl esters on two different stationary phases, a polar polyester (*LHC-R*-296)[5] and silicone oil[4]. In addition chromatograms were performed on the mixed esters after complete hydrogenation in order to obtain an accurate chain-length analysis. The analytical procedures used in addition have been described earlier[6]. The results of the analysis are summarized in Table 1. The most striking differences between animal groups *A*, *B*, *C* and *D* were found in the cholesterol ester fatty acid composition. The cholesterol esters of the control group *A* contained only 23·1 per cent oleic acid compared with 64·2, 41·8 and 48 2 per cent in animal groups *B*, *C* and *D* respectively. The stearic acid concentration on the other hand decreased from 13·4 per cent in the control group *A* to 2·1, 5·2 and 8·1 per cent in groups *B*, *C* and *D*. The linoleic acid concentration of the cholesterol esters showed no significant changes in the different animal groups.

In the triglycerides the percentage of oleic acid showed similar changes as in the cholesterol esters but less pronounced. The percentage of stearic acid showed, however, only a tendency to decrease and the percentage of linoleic acid showed no differences.

The fatty acid composition of the phospholipids in the groups was remarkably constant with the exception of group *D* where an increase in fatty acids belonging to group C_{20-24}? was found. The exact nature of these fatty acids has still to be determined.

In connexion with the pronounced changes in the oleic acid and stearic acid percentage in the cholesterol and triglyceride fatty acids found here two papers are relevant. Klein and Martin[7] have found an increase in the liver cholesterol oleate pool of cholesterol-fed rats. James *et al.*[8] have described an increase in oleic acid and a decrease in stearic acid percentage in the fatty acids of the acetone-soluble lipids of plasma from patients with coronary artery disease.

Concerning the influence of diet in these experiments, it is apparent that without any additions to the diet the stilbœstrol-treated animals showed changes in the cholesterol ester and triglyceride fatty acids similar to the changes found in the two cholesterol-fed groups. All three treated groups showed hyperlipæmia and cholesterol accumulation in the aorta.

The implications of these observations can be more properly assessed when the fatty acid composition of the plasma lipids is also known.

This work is part of investigations supported by the Swedish Medical Research Council and King Christian X's Fund.

GROWTH AND MORPHOGENESIS OF *STRIGA* SEEDLINGS

By COLIN N. WILLIAMS*
University College, Ibadan, Nigeria

Effect of Light, Gibberellic Acid and Kinetin on Growth and Morphogenesis of *Striga* Seedlings

BOTH facultative and obligate parasites occur in the family Scrophulariaceae. An example of the former is *Rhinanthus minor* Linn.[1], which can grow without the host, producing roots and shoots as a normal plant and even setting seed. The growth of such plants, however, is generally slower, and the plants may be stunted compared with those which become attached to a suitable host. Among the obligate parasites belonging to this group, species of *Striga* are well known for attacking grain crops in tropical and sub-tropical countries. The seeds of these parasites require a germination stimulus which is produced by the roots of host plants. Saunders[2] demonstrated that leachings from sand in which the roots of maize had been growing could be used to germinate *S. asiatica* (= *S. lutea*) and to grow the seedlings for a short period without the host. In the present experiments a solution produced by growing a susceptible variety of *Sorghum vulgare* in small pots of sand for a number of days and eluting with water was used to germinate seeds of *S. asiatica*. In this solution seedlings produced a slender unbranched radicle (Figs. 1 and 2) up to 4 mm. long, but generally less, before the food reserves in the seeds were used up and the seedlings died. The radicle was usually strongly curved at first or grew in the form of a spiral, and root hairs were not generally produced although a few short hairs sometimes grew towards the radicle tip of older seedlings, and occasionally an abnormal, highly deformed seedling which sprouted root hairs was produced in such cultures.

The effects of light and the growth substance gibberellic acid and kinetin on this morphogenic pattern have been studied. In the growth-substance experiments young germinated seedlings (between 15 and 30 in each replicate) were transferred to small culture vessels in 1 ml. of the germination solution. To this was added 4 ml. of either water or the particular hormone solution under investigation. The cultures were maintained in the dark except for short periods when they were examined. Growth was recorded by means of camera-lucida drawings or photographically. In the light experiments seedlings were exposed to light of different qualities or kept in the dark. A No. 2 Photoflood lamp was used as a light source. The light was filtered through an infra-red filter and a water filter circulated with air-cooled water. This arrangement permitted the treatment of seedlings with fairly high-energy light without heating; light of restricted wave-length was obtained by the use of coloured glass filters. These were matched for equal energy transmission (using a simple thermopile and galvanometer) with a series of neutral filters made by reducing fogged (black) photographic film to the desired density. The accuracy of the thermopile and galvanometer permitted only approximate matching of the filters. The unfiltered light (about 2,500 ft.-candles at the level of the culture vessel) gave a galvanometer reading of 8 units, while the densest filter used gave a reading of 1·5 units. The neutral filters were used to adjust the other filters to give this reading on the thermopile galvanometer. Using this arrangement, only one light treatment could be studied at a time so that each result is compared with a separate dark control. The results of the light experiments are shown in Table 1.

The major effects of light were: (1) reduced extension growth of the radicle; (2) increased diameter; (3) the production of root hairs; (4) the occasional proliferation of cells into a branch-like swelling of the radicle. The number of root hairs shown in Table 1 refers only to those that were countable in a profile view of the seedlings, the actual numbers being considerably higher than this (some

Table 1. EFFECT OF LIGHT OF DIFFERENT QUALITIES ON DEVELOPMENT OF THE *Striga* RADICLE

Light quality	Transmission range of filter (mμ)	Max. transmission (mμ)	Extension growth light growth/dark growth	Diam. light/dark	Root hairs (av. per seedling over controls)
White	—	—	0·31	1·8	8·1
Blue	*c.* 350–650	490	0·45	1·6	7·4
Green	470–650	540	0·81	1·3	2·1
Red	600–*c.* 1,100	*c.* 650	0·68	1·3	2·5
Far-red	700–*c.* 1,100	*c.* 770	1·06	1·0	0

typical effects of light are illustrated in Figs. 3–5). The most effective wave-lengths in producing these morphogenic effects were in the blue region of the spectrum and to a lesser extent in the red. Far-red irradiation produced a slight, though not significant, increase in extension growth and was without formative effects. It was not tested whether far-red could reverse the effect of fixed exposures to light of the other wave-lengths. While the effects of red and far-red in many plant growth processes are reversible through the action of red and far-red absorbing forms of a special pigment system (for example, seed germination, flowering, internode extension, hypocotyl curvature, anthocyanin synthesis)[3–6], some plants are reported to be more sensitive to blue irradiation[7] in flowering and growth responses. According to Hendricks and Borthwick[6], photomorphogenic responses to blue light also arise from the absorptions of the photomorphogenic pigment. That the situation is probably more complex is indicated by the results of Stozwijk and Zeevaart[8] in which both blue and far-red were found to be more effective than red in promoting flowering of the long-day plant *Hyoscyamus niger*, while generally flowering of long-day plants appears to respond to red (and to be inhibited by far-red).

Gibberellin and kinetin are known to simulate certain effects of light ; both promote leaf expansion and seed germination, while gibberellin simulates the effect of red light on the flowering of long-day and short-day plants (see review by Brian[9]). Brian postulates the action of red light in raising the level of a gibberellin-like hormone which may in some way affect the auxin status of plants. The effects of these substances on the development of *Striga* seedlings are shown in Table 2.

Kinetin had a striking effect on root hair production and radicle growth resembling the effects of light (Figs. 6–9). Root hair production and length of hairs were greatest at 1 p.p.m. and least at 100 p.p.m. At the 1 p.p.m. level kinetin induced branching in the radicle of some seedlings, with pro-vascular strands passing from each branch (Fig. 9). At the 10 p.p.m. level, and to some extent at the 100 p.p.m. level, shoot development shown by expansion of the cotyledons and enlargement of the plumule were stimulated. (The effects of kinetin on root hair production and shoot development have been previously reported by Worsham *et al.*[10], who also report that kinetin at certain levels promotes germination of the parasite seeds. The resemblance of the effects of kinetin and light, however, has not to my knowledge been previously reported.)

The action of gibberellic acid resembled that of kinetin in inducing shoot development and branching of the radicle in some seedlings. With this substance, however, the radicle branches were more elongated and extension growth was not reduced to the same extent (Figs. 10 and 11) : gibberellic acid had no significant effect on root hair production under these conditions, although it has been reported to promote root hair formation in excised pea roots[11]. Shoot development was pronounced with gibberellic acid at 5 and 25 p.p.m. and differed from kinetin in showing definite internode extension (Fig. 11). Clearly gibberellic acid does not simulate the effect of light in the development of *Striga* seedlings as does kinetin.

The morphogenic changes induced by light and these growth substances are of particular interest, since development in the dark beyond the stage of radicle extension in *Striga asiatica* normally only occurs if the parasite becomes associated with a suitable host plant. The production of shoots and the stimulation of root branching by kinetin and gibberellin indicate that the parasite probably depends on a supply of growth factors of this type from the host for development, unlike the facultative parasites belonging to the same family (for example, *Rhinanthus*). Shoot development has never been observed to occur with light treatment alone. Various attempts have been made to prolong the growth of *S. asiatica* in culture by providing mineral nutrients and certain vitamins and organic compounds (for example, thiamin, nicotinic acid, pyridoxine, adenine), as well as kinetin, gibberellic acid and light; but chlorophyll development and growth beyond the stages indicated have never occurred.

Influence of the Host Rhizosphere on the Morphogenesis of *Striga* Seedlings

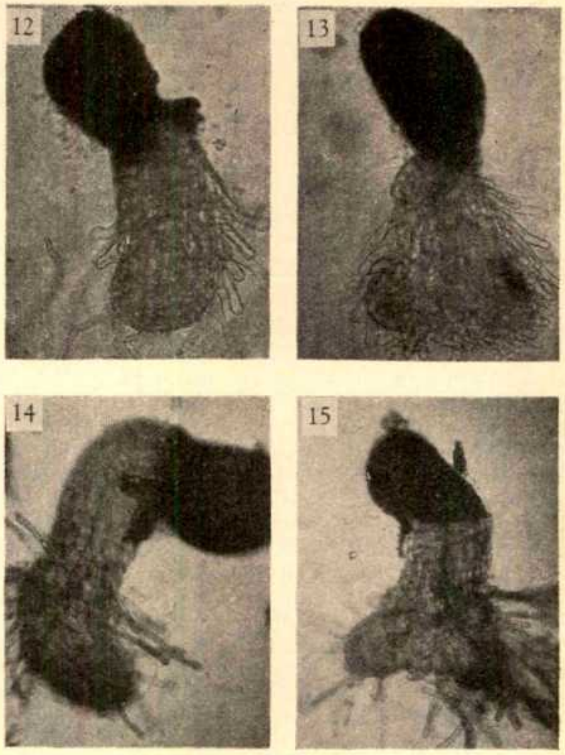
USING an agar culture technique, studies have been made on the development of the radicle of the root parasite *Striga asiatica* (= *S. lutea*) in the rhizosphere of a susceptible host plant. The method used was as follows: parasite seeds were treated with moisture on damp filter paper for about 10 days before use. The seeds do not normally germinate except in the presence of an exudate from the roots of a host plant (for example, sorghum, maize), and a period of moisture treatment is necessary for optimum germination. After moisture treatment the parasite seeds were mixed into an autoclaved 1 per cent agar solution at about 40–45° C., pipetted into 6-cm. Petri dishes and allowed to set. 10 c.c. of the agar seed suspension was pipetted into each dish (that is, several hundred seeds). Immediately after pipetting the agar, one host seedling (*Sorghum vulgare* var. Light Mori, from Nigeria) was rinsed briefly with sterile water and planted in each dish. The host seeds were surface sterilized with bromine water prior to germination, and the radicles at the time of planting were about 2 cm. long. The dishes were incubated in the dark at room temperature at a slight incline to induce the host radicles to grow across the dishes. Five or ten replicates were used, and the experiment was repeated on a number of occasions.

A germination factor, diffusing from the host radicle, caused the parasite seeds to germinate. Germination varied considerably between the replicates, but always increased with proximity to the host radicle. In addition to germination, growth-rate and morphology of the radicle varied strikingly with distance from the host radicle. The development of the parasite radicle in 4-mm. zones about the host root was measured by means of camera-lucida drawings. In the nearest zone the rate of extension growth of the radicle was very low, the radicle undergoing considerable lateral expansion and producing root hairs (Fig. 12). Occasionally branching of the radicle occurred (Fig. 13). In this zone the host root showed a definite positive chemotropic influence over the growth of the parasite radicle. In the second zone (4–8 mm. from the host root) the rate of extension growth of the parasite radicle was considerably increased, and lateral expansion and the production of root hairs were reduced. Similarly, in the third zone (8–12 mm. from the host root) the rate of extension growth was further increased and lateral expansion and root hair formation reduced. These results are listed in Table 3.

Table 3. MORPHOGENIC EFFECT OF THE HOST RHIZOSPHERE ON THE RADICLE OF THE ROOT PARASITE *Striga asiatica*

Distance from host root	Root hairs* (average per seedling)	Extension growth (mm.)	Diameter (mm.)
0–4 mm.	12·2	0·45	0·16
4–8 mm.	2·7	0·95	0·13
8–12 mm.	1·5	1·25	0·10

* Only the root hairs visible in profile were counted; the actual numbers were considerably higher.



Figs. 12 and 13, typical morphogenic effects of the host rhizosphere; Figs. 14 and 15, effects of kinetin at a concentration of 1 p.p.m.

The results show that a factor having a strong morphogenic influence on the development of *Striga* seedlings is present in the host rhizosphere and is probably secreted by the host-plant root. It is of interest that similar effects on the development of *Striga* seedlings can be induced in cultures without the host by treatment with light (particularly blue light and to a lesser extent red), and with the light-simulating hormone kinetin [6-(2-furfuryl) amino-purine] (ref. 10 and previous communication). Figs. 14 and 15 show typical effects of kinetin at a level of 1 p.p.m. on *Striga asiatica* seedlings. Root hair production and lateral expansion of the radicle are stimulated and extension growth is strongly reduced, while some seedlings are induced to branch in a way very similar to that which occurs in the region of the host root. At higher levels (10 and 100 p.p.m.) shoot development was stimulated by kinetin. No shoot development was ever observed to result from exudates in the rhizosphere of the host, however, although shoot development commences shortly after contact is made with the host root.

Worsham *et al.*[10] have shown that certain 6-substituted amino-purines, including kinetin, stimulate the germination of *Striga asiatica* seeds at levels ranging from 5 to 25 p.p.m., and can replace the natural germination stimulant excreted by the host roots. The natural germination stimulant has not, to my knowledge, been identified, although chromatography of concentrates prepared from water in which the roots of sorghum had been growing revealed a highly active zone close to the solvent front[12]. This stimulant was thought to be similar to the *Orobanche* seed stimulant from linseed roots, which apparently also stimulates the germination of *Striga* seeds and has a similar R_F value[13]. Degradative work on the *Orobanche* stimulant, however, has shown it to have a small nitrogen value (0·5 per cent)[14] and therefore it does not appear to be a purine compound. A more recent investigation[15] on the *Striga* and *Orobanche* germination stimulants from maize roots shows that root extracts, and aqueous solutions in which the roots have been suspended, contain a number of stimulating substances for these seeds, including a water-soluble component and a number of ether-soluble components. Chromatographic analysis indicates that the factors from maize roots causing optimal germination of *Striga* and *Orobanche* seeds are different. Traces of solutions from linseed and sorghum roots acted synergistically with maize root preparations, suggesting that linseed, sorghum and maize may all produce a similar complex of stimulants, differing only in the proportions of the different constituents.

In view of the present results and the demonstration by Worsham *et al.*[10] that 6-substituted aminopurines can stimulate the germination of *Striga* seeds, it would seem possible that one of the components of the germination complex may be a kinetin-like compound, which both stimulates the germination of the parasite seeds and induces morphogenic changes in the seedlings. In this case the concentration required for germination would be considerably less than that required for the appearance of morphogenic effects.

ACTION POTENTIAL WITH AN ARTIFICIAL *p*H-MUSCLE

By D. H. WALTERS, PROF. W. KUHN and HANS J. KUHN

Physical Chemistry Institute, University of Basle

An artificial *p*H-muscle[1] consisting of a three-dimensional network, made from about equal quantities of polyvinyl alcohol and polyacrylic acid, has previously been shown to dilate and to contract reversibly when sodium hydroxide and hydrochloric acid was added alternately to its embedding medium, for example, 1×10^{-3} *N* sodium chloride solution. It was consequently demonstrated for the first time with the artificial cross-striated *p*H-muscle[2] that the chemically induced dilations and contractions are paralleled by chemical equilibrium changes if the length of the filaments are changed mechanically. These chemical equilibrium changes were also shown to occur in an analogous way with the homogeneous *p*H-muscle[3], the redox-[4] and the ion-precipitation-muscle[5]; and they are the basis for a transformation of chemical into mechanical energy by means of these systems and the establishment of corresponding general and quantitative relationships: the 'teinochemical principle'[6].

In the course of comparing the behaviour of the artificial *p*H-muscle with the properties of the natural muscle, the potential between the inside of the artificial *p*H-muscle and its embedding medium was determined in a series of preliminary experiments, during: (1) an initial state of thermodynamic equilibrium, and then sequentially in (2) the various stages following a contraction or dilation stimulus. The latter potentials (2) will be seen to vary with time and may be referred to as action potentials, being characteristic for a system in which the dilations or contractions with the corresponding time-dependent interior changes are at the start, or in the subsequent course, of development.

High-polymer heat-vulcanized gel strips, consisting in the dry state of equal parts of polyvinyl alcohol and polyacrylic acid, were prepared and the polyacrylic acid content was partially (for example, 20 per cent) neutralized by placing the foils in an appropriate quantity of dilute aqueous sodium hydroxide. The partially neutralized gel strips were afterwards embedded in an aqueous 1×10^{-3} *N* sodium chloride solution, the volume of which was less than 100 times the swollen gel volume (for example, 4·0 cm. × 3·0 cm. × 1·0 cm.). After complete equilibrium with respect to both swelling and *p*H had been established between the swollen gel strip and its embedding medium, a small quartz capillary (filled with agar–agar and saturated potassium chloride, and which was connected to a saturated potassium chloride–calomel electrode) was inserted into the swollen gel strip; the capillary end of a second and similar electrode assembly was introduced into the embedding medium. The electrical circuit was completed by connecting the metallic ends of the saturated potassium chloride–calomel electrodes to a calibrated Polymetron type 42*B* millivolt meter. A more detailed description of the experimental apparatus, conditions and procedure will be given elsewhere[7].

In the ensuing time–potential curves (Figs. 1–3*a*, *b*) the potential of the electrode inside the gel relative to the electrode in the embedding medium is represented by the ordinate, the time by the abscissa. On inserting the internal electrode into the chemically stretched polyvinyl alcohol plus polyacrylic acid swollen gel strip (that is, a gel the polyacrylic acid content of which had been partially neutralized with aqueous sodium hydroxide), a potential is obtained which is represented by point *A* of curve *ABCD* in Fig. 1. This potential, which is constant in time (cf. part *A*–*B* of curve *ABCD* in Fig. 1) and negative with respect to the embedding medium, corresponds to a state of equilibrium between the gel strip and the embedding medium; it is identical with the Donnan potential[8] existing at the surface of the gel and the surrounding fluid.

With the addition of hydrochloric acid (for example, 3 c.c. of 0·1 *N*) to the embedding medium of the partially neutralized polyvinyl alcohol plus polyacrylic acid swollen gel strip (point *B* of curve *ABCD* in Fig. 1) a contraction stimulus is applied to the gel. The potential rises rapidly from a negative value (point *B* of curve *ABCD* in Fig. 1) to a highly positive value (point *C* of curve *ABCD* in Fig. 1) and then gradually decreases with increasing time to a final value (point *D* of curve *ABCD* in Fig. 1). The potential drops to zero (example, point *D* in Fig. 1) if the amount of hydrochloric acid added to the embedding medium is sufficient to convert all of the sodium polyacrylate in the gel to polyacrylic acid.

The potentials represented by points *A*, *B* and *D* in Fig. 1 are equilibrium potentials; they are completely accounted for by the respective ion concentrations in the gel and the embedding medium. The potentials between points *B* and *D*, in particular the potential at point *C* of Fig. 1, correspond to a non-equilibrium state of the system. Point *C* of curve *ABCD* in Fig. 1 (the spike of the overshoot of the time–potential curve) represents the potential of the chemically stimulated partially neutralized polyvinyl alcohol plus polyacrylic acid swollen *p*H-muscle at the point of its first major perceptible contraction (ref. 7*a*). Qualitatively, the positive potential value of the gel at point *C* (Fig. 1) is due to the hydrogen ions moving from the acidified embedding medium into the interior of the gel, the product of concentration and mobility of the hydrogen ions being the highest of all ions that are present at the interface of the gel and therefore dominating the potential. In the subsequent time period (between point *C* and point *D* of Fig. 1) the details of the explanation become more complicated; the concentration gradients due to ionic diffusion both inside and outside the gel, the reaction of the sodium polyacrylate with the hydrochloric acid, and the general or local contraction of the gel, will develop and may lead to local potential gradients of different sign and magnitude. The observation of a strong peak of positive potential after the administration of the chemical contraction stimulus is the main feature of curve *ABCD* of Fig. 1.

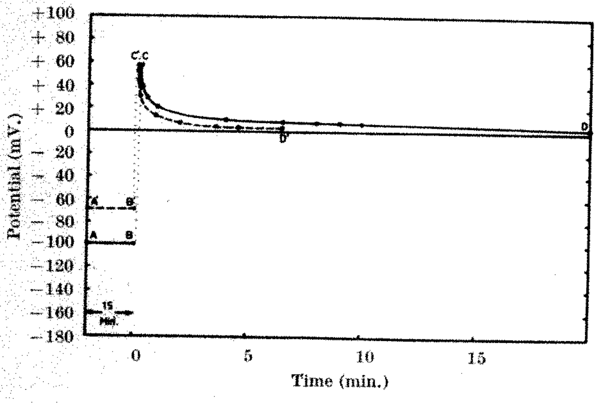

Fig. 1. Time–potential curves produced at 20° C. by hydrochloric acid on: (1) Partially neutralized swollen polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1 × 10^{-3} *N* sodium chloride solution (curve *ABCD*); addition of hydrochloric acid to the embedding medium at time zero, corresponding to point *B*; first major perceptible contraction begins at point *C* and accompanies the time–potential curve *C*–*D*
(2) Acidified swollen non-contractile polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1 × 10^{-3} *N* sodium chloride solution (broken curve *A'B'C'D'*); addition of hydrochloric acid to embedding medium at time zero, corresponding to point *B'*; no perceptible contraction of this (acidic) gel strip

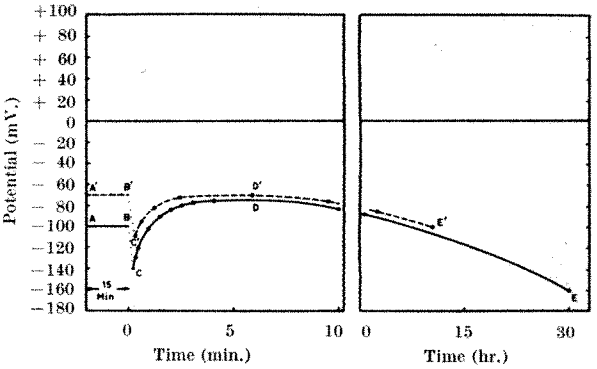

Fig. 2. Time–potential curves produced at 20° C. by sodium hydroxide solution on:
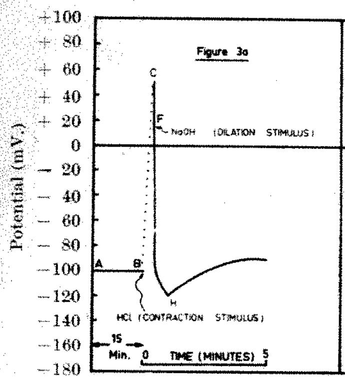
(1) Partially neutralized swollen polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1 × 10^{-3} *N* sodium chloride solution (curve *ABCDE*); addition of sodium hydroxide solution to the embedding medium at time zero, corresponding to point *B*; first major perceptible dilation of gel strip begins at point *C* and accompanies the time–potential curve *CDE*
(2) Acidic swollen non-contractile polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1 × 10^{-3} *N* sodium chloride solution (broken curve *A'B'C'D'E'*); addition of sodium hydroxide solution at point *B'*; first major perceptible dilation (relaxation) begins at point *C'* and ends at point *E'*
Serrated edges of time–potential curves represent time-lapse

The effect of hydrochloric acid on an acidic swollen non-contractile polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1 × 10^{-3} *N* sodium chloride solution is represented by curve *A'B'C'D'* and text in Fig. 1; a more detailed discussion will appear elsewhere[7].

When a partially neutralized or acidic polyvinyl alcohol plus polyacrylic acid gel strip, again prepared and embedded in 1 × 10^{-3} *N* sodium chloride solution as in the previous experiments, is given a dilation stimulus by the addition of sodium hydroxide solution (for example, 3 c.c. of 0·1 *N*) to the embedding medium, an immediate potential peak of the opposite sign is observed (that is, the internal gel electrode becomes more negative relative to the outer electrode in the embedding medium (Fig. 2)).

The peak of the negative potential (points *C'* and *C* of Fig. 2, that is, the point where the alkali-stimulated gel begins its first major perceptible dilation) is followed by a drop of the absolute value of the negative potential and after a long period by a moderate increase of the negative potential value towards a final equilibrium value which again can be explained by the state of gel swelling, and of the ion concentration both inside and outside the gel present in the final equilibrium state: curves *ABCDE* amd *A'B'C'D'E'* of Fig. 2.

It is interesting to note that a contraction stimulus (produced by the addition of acid to the embedding medium) followed a short time later by a dilation stimulus (a relaxation stimulus produced by the



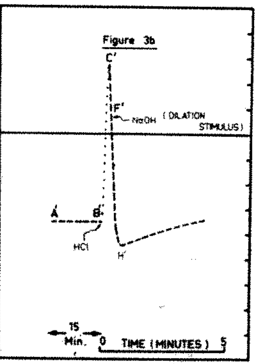


Fig. 3*a*. Time–potential curve for the effect of hydrochloric acid (contraction stimulus) followed a short time later by the addition of sodium hydroxide solution (dilation stimulus) on a partially neutralized polyvinyl alcohol plus polyacrylic acid swollen gel strip embedded in 1×10^{-3} N sodium chloride solution; this curve is a superimposition of curve *ABCD* of Fig. 1 on curve *ABCD* of Fig. 2 with a small time shift of the latter curve. Hydrochloric acid added at point *B*; first major perceptible contraction would be observed, under the present experimental conditions, at point *C*. Sodium hydroxide solution added at point *F*; dilation would begin shortly after point *F* and continue until the final equilibrium point. The significance and means of varying the slope and duration of the line *CFH*, and the recovery period beyond point *H*, will be presented elsewhere (ref. 7)

Fig. 3*b*. Time–potential curve for the effect of hydrochloric acid followed a short time later by the addition of sodium hydroxide solution (dilation stimulus) on an acidic swollen non-contractile polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1×10^{-3} N sodium chloride solution; this curve is a superposition of curve *A'B'C'D'* of Fig. 1 on curve *A'B'C'D'* of Fig. 2 with a small time shift of the latter curve. No perceptible contraction of gel strip on addition of hydrochloric acid. Remainder of legend as for Fig. 3*a*

addition of alkali to the embedding medium) of the swollen partially neutralized gel strip will produce a time–potential curve (for example, Fig. 3*a*) which has many of the characteristics of the time–potential curve (that is, of the action–potential curve) of various biological tissues[9]; in fact, the same curve of Fig. 3*a* is produced by a superimposition of curve *ABCD* in Fig. 1 on curve *ABCD* of Fig. 2 with a small time-shift of the latter curve.

Fig. 3*b* shows the effect of the addition of hydrochloric acid followed later by the addition of sodium hydroxide solution on a swollen non-contractile acidic polyvinyl alcohol plus polyacrylic acid gel strip embedded in 1×10^{-3} N sodium chloride solution; this will be discussed at greater length elsewhere[7].

A comparison of the resting, action and recovery potentials observed with various biological tissues[9] and the potentials observed with the high-polymer pH-muscle reveals some obvious formal analogies. Further ways of producing by appropriate means in other artificial high-polymer systems (for example, cross-striated pH-muscle, redox- and ion-precipitation-muscle) potentials dependent on time and similar to the different action–potential curves of various biological tissues will be given elsewhere[7]. Subsequent papers will also include the more complicated time–potential curves for high-polymer systems when acids and/or bases and other chemical substances are introduced either separately or in combination into the interior of the neutralized or acidic gel and/or the embedding medium at the same time or after a specific time lag, plus a discussion of the chemical and physical properties which influence the specific time–potential curve[7].

PHOTOGRAPHIC CUMULATION OF RECURRENT RESPONSE POTENTIALS

By Prof. LORRIN A. RIGGS and C. R. CAVONIUS
Hunter Laboratory of Psychology, Brown University, Providence, Rhode Island
AND
Dr. E. PARKER JOHNSON
Colby College, Waterville, Maine

INTERMITTENT illumination of the human eye elicits a corresponding succession of response potential waves in the electroretinogram. Lord Adrian[1] has shown that these waves have negative and positive components the form of which is related to the frequency and intensity of the stimulating flashes. Much interest now centres on isolating the small responses characteristic of the photopic or colour-specific systems of the eye[2,3]. Unfortunately, a relatively large background of electrical 'noise' is usually present in an actively responsive system such as the eye. Often it is true that the signals generated in response to the light are smaller than the 'noise' that is unrelated to the stimulus.

One time-worn procedure for separating evoked potentials from irrelevant ones has been the comparison of several samples of record made under conditions such that they ought, apart from contamination, to appear identical. This is helpful; but the unaided eye is incapable of making these comparisons in a completely unbiased manner, and most workers agree that the required integration and abstraction would be better carried out using some more objective procedure. The use of electronic computers offers an exciting prospect of unheard-of sensitivity in the recording of biological potentials[4]. The apparatus, however, is complex and costly. It is usually not feasible to occupy such elaborate equipment throughout the routine, day-after-day exploration of individual electrophysiological phenomena.

The present article describes a simpler procedure, one which stores and cumulates its information on photographic film during successive exposures. We have applied the method specifically to the registration of the electroretinogram and have been able to identify components with amplitudes of less than one microvolt. The principle appears easily adaptable to any of a broad range of problems in which the response is stimulus-locked.

Our apparatus for cumulating electrophysiological responses is illustrated in Fig. 1. Light from a small tungsten filament is collected by a spherical mirror, directed through a rectangular aperture, and focused on the mirror of a bifilar oscillograph galvanometer having a natural frequency of 4,000 cycles/sec. A collimating lens in front of the galvanometer provides an image of the aperture in the form of a uniformly illuminated, rectangular patch of light. The rays forming this patch are reflected downward by a right-angle prism on to a horizontal diaphragm pierced by two rectangular windows. Any deflexion of the galvanometer mirror causes a proportional amount of light to traverse window *N* or window *P*, depending on the direction of movement of the mirror. In the null position the light falls between the two windows, illuminating neither.

When the eye is stimulated by a flash of light the negative and positive phases of the ensuing retinal potential, as amplified and fed into the galvanometer, are represented in the amounts of light traversing windows *N* and *P*. To record this, a cylindrical drum is wrapped with photographic film and rotated on a shaft directly below the windows of the diaphragm. A cylindrical lens focuses the light coming through the two windows on to the drum as two narrow lines of light. These, as the drum rotates, make parallel ribbons of exposure on the film, representing windows *N* and *P*.

To use the device for the cumulative recording of evoked potentials it is only necessary to synchronize the stimulus with the rotation of the drum. We have mounted a flicker-vane with four open sectors on the same shaft as the recording drum. Light passing through the open sectors provides the eye with a succession of flashes each of which evokes a response actuating the oscillograph galvanometer. A shutter is then opened, admitting the light to the rotating film for a fixed period of time—long enough to include the responses to several hundred flashes. The developed film appears as in Fig. 2. Variations in density indicate the existence of synchronous responses; randomly occurring 'noise' only adds a nearly uniform darkening of the two tracks. In our system, with four flashes per revolution, we see four cycles of density variation on each pair of tracks.

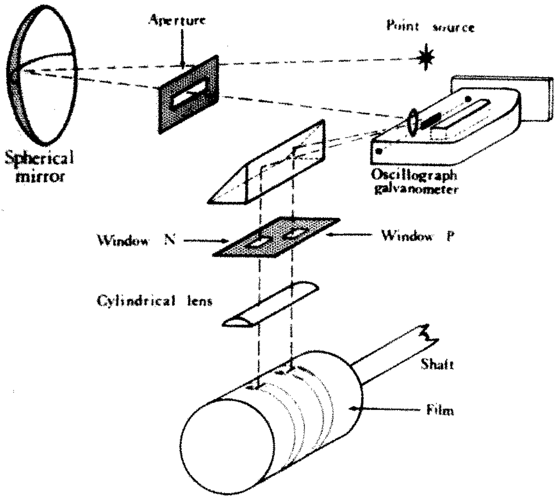

Fig. 1. The optics of the photographic cumulator—a schematic representation

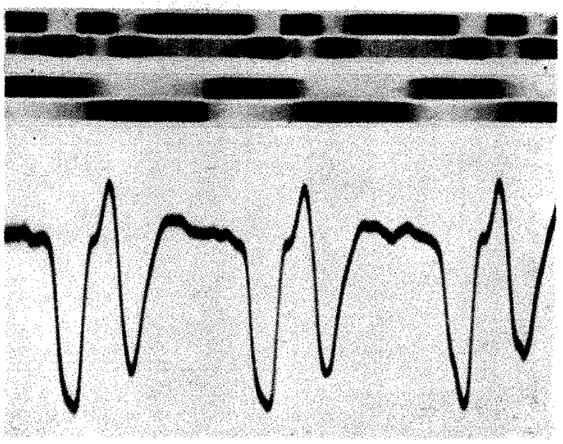

Fig. 2. Film records of cumulated electroretinal responses at two different flicker-rates, 30 per sec. (bottom pair) and 10 per sec. (top pair). The latter pair has been scanned with a recording densitometer to yield the 'average response' pattern shown beneath. Three response cycles are shown, each one being a cumulation of 75 individual responses

To 'read' our film records we use a double-beam densitometer and record the difference in density, between the two tracks, as a function of phase position. An oscillographic record of the output of the densitometer appears below the film in Fig. 2. This record shows the main features of the response without serious contamination by background 'noise'. Calibration of the system shows that it is reasonably linear despite the fact that film density is logarithmically related to exposure. This is because the method is one in which the final result is given by relatively small differences in densities that are nearly equal between the two tracks. For more exact determinations of the absolute potential-levels it would be necessary to develop the negative under conditions resulting in a photographic gamma of unity, printing a film positive under the same conditions, and finally scanning this positive with photocells having a linear response to light intensity.

The optical method of cumulation has proved its ability to reduce irrelevant potential 'noise' and hence to reveal stimulus-locked responses of very low amplitudes. We are now able to record electroretinographic responses to light that is flickering at a rate considerably higher than the critical frequency of fusion as seen by the observer. The method has the disadvantage that conditions of exposing, developing and scanning the photographic film must be given careful consideration and selected for appropriateness. It has the advantages of simplicity, reliability and low cost, coupled with the fact that there is continuous rather than discrete time-sampling of the response potentials.

PHYSICS

High Strength Glass

It was reported recently[1] that the major stress-raising defects on the surface of freshly drawn fibres of glass are visible, local defects which arise through the interaction of the hot glass with dust particles or other contamination. In that work very approximate values of the tensile stress which small areas of the surface, free from visible defects, would withstand without fracture were obtained. This communication is to report some results of further experiments to measure the actual breaking strengths of 'defect-free' samples of several commercial glasses.

Two methods have been used to prepare fibres of diameter 350–700μ which are free from visible defects, and these have been tested in 3-point bending using a gauge-length of 7 mm. and knife edges covered with polytetrafluoroethylene. For the first series of experiments lengths of fibre were produced by hand drawing from sections of ¼-in. diameter commercial rod which had been etched in 20 per cent hydrofluoric acid immediately before drawing. The centre of the rod was heated in an oxygen–coal-gas flame until quite fluid, removed and allowed to cool slightly before drawing. In a series of draws occasional defects are to be found, so that this simple procedure is not ideal. However, it has been found possible to eliminate from the results the more obvious cases of samples weakened by the presence of a defect, as described here. For the second series of experiments no precautions were taken to prevent the formation of defects during the heating of the rods before drawing. Instead, they were removed from the surface of the fibres after drawing by etching in hydrofluoric acid.

A sufficiently prolonged attack leaves smooth saucer-shaped pits in the fibre surface at the sites of the original defects. For samples of ×8 glass, etching for 5 min. in a 10 per cent solution of hydrofluoric acid was sufficient to achieve this, and reduced the diameter by approximately 60μ. Samples etched for 10 min. in the same solution did not show significantly different strengths. Similar treatment of 'Pyrex' specimens removed much less material; the strengths

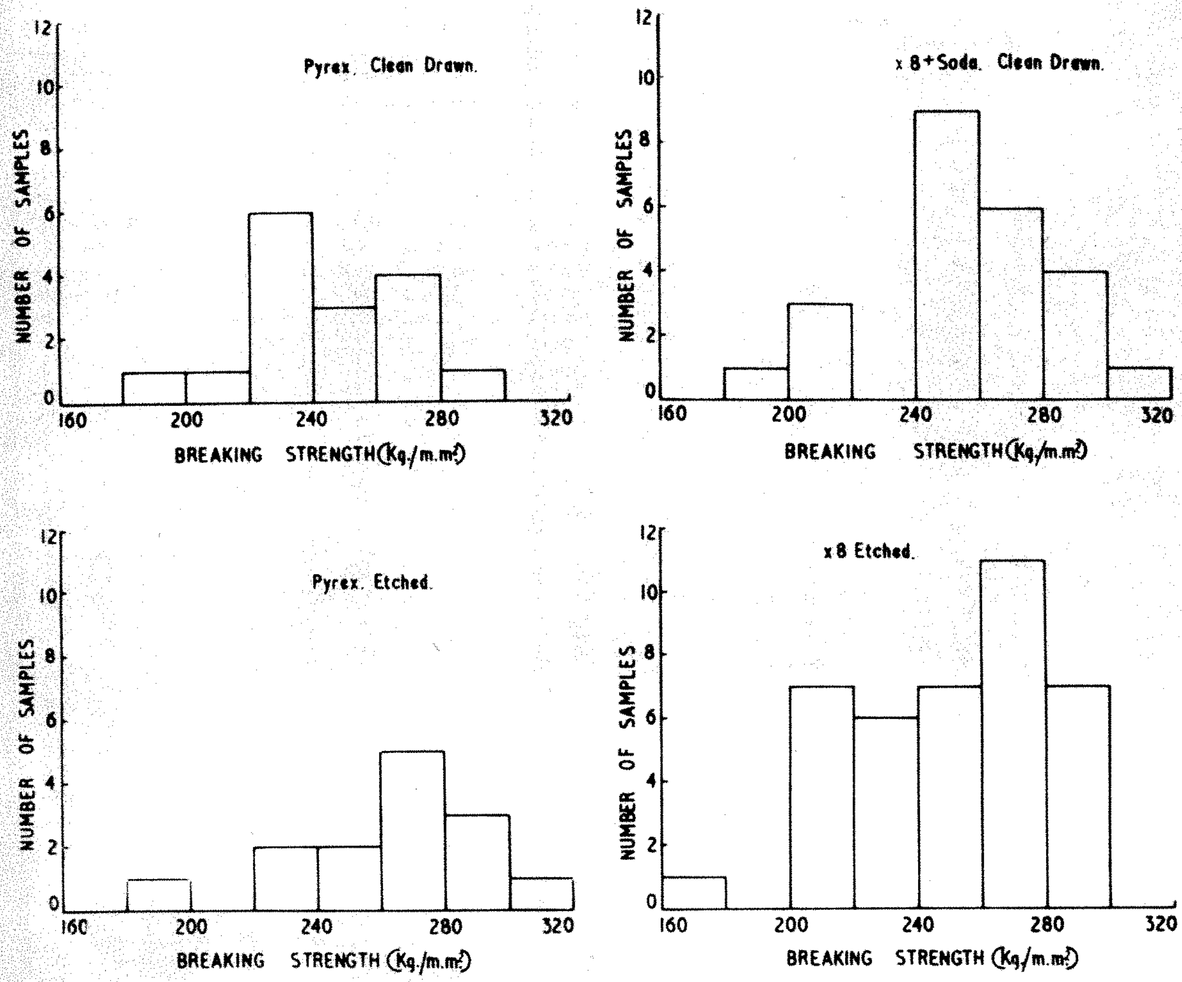

Fig. 1. Histograms illustrating the results obtained with 'Pyrex' and soda–lime–silica glasses

Table 1. SUMMARY OF RESULTS. IN THE SECOND COLUMN *C* INDICATES 'CLEAN DRAWN' SAMPLES AND *E* INDICATES ETCHED SAMPLES

Glass		Type of sample	No. of samples	Mean strength (kgm./mm.^{2})	Coefficient of variation
E-glass		*C*	24	343	7
Soda-Lime	×8	*C*	11	251	10
	×8	*E*	39	250	12
	Unknown	*C*	13	257	12
'Pyrex'		*C*	16	242	10
		E	14	265	11
Silica ('Vitreosil')		*C*	23	350	8
		E	11	361	11

were lower and the pits were more angular. Immersion for 5 min. in a 40 per cent solution did, however, yield appreciable attack and smooth shallow pits. It is the results for these samples which are quoted in Table 1.

The diameters of the broken ends of the specimens were measured with a micrometer eyepiece attached to the microscope. With the strong specimens considerable shattering occurred so that it was not possible to measure the diameter at the position of fracture, nor indeed to locate the origin of fracture. This feature did, however, enable us to eliminate from the results the comparatively few samples from the first series which failed at a 'defect', for when shattering did not occur it was possible to examine carefully both fracture surfaces and invariably to detect a visible defect at the edge of the mirror zone.

The breaking strength was assumed to be the maximum tensile stress at the surface and was computed using the simple formulæ for the stresses in a bent beam. Quite large deflexions do occur in these tests, but from the expressions given by Freeman[2] the errors involved in using the simple equations for the stresses do not exceed 2 per cent for most of the fibres and are less than 10 per cent for the finest.

The histograms of Fig. 1 illustrate the results obtained with 'Pyrex' glass and soda–lime–silica glasses, while all the results obtained in this preliminary series of experiments are summarized in Table 1. The results for etched *E*-glass fibres are not included because for this glass the reaction was complicated by the growth of layers of reaction product at the glass surface, and etching in hydrofluoric acid has not proved satisfactory for removing defects to leave a smooth surface.

Tests were made with the first type of sample at times varying from 4 min. to several days after production. No significant differences were observed in the strengths. Some of the etched samples were tested while still wet with distilled water from the rinsing bath; these also showed no significant difference in strength.

We conclude that the high and relatively consistent values of the breaking strength obtained in these experiments support quantitatively the suggestion made earlier that the visible defects are a major source of surface weakness[1]. The strengths are comparable with those obtained by Thomas[3] and Otto[4] for very fine fibres of *E*-glass, although still lower than that expected from theoretical estimates which assume a homogeneous structure for a glass.

The residual scatter in our results is larger than is to be expected from experimental errors, which is estimated to be less than ± 10 per cent for any individual determination. Since the magnitudes and the variabilities are similar for both the 'clean draw' and the etched samples of the several glasses, it seems unlikely that the scatter is due to undetected defects of known type in the surface. It has been established that the scatter in breaking strength for × 8 samples rises significantly when deliberate variations are made in the interval between removal of the rod from the flame and drawing the fibre. We think, however, that detailed discussion of these results and of the possible causes of the residual variability in strength should await the results from further experiments which are now in progress. These will enable samples to be produced under more carefully controlled conditions, to be annealed without the formation of fresh surface defects and to be tested so as to avoid any perturbing effects from the knife edges.

Tortuosity in Porous Media

THE tortuosity, T, of a porous medium such as sandstone is a quantity that has been interpreted in various and sometimes conflicting ways, particularly its relation to porosity, φ, and formation factor, F (refs. 1–4). Tortuosity originally was understood to mean the square of the quotient average length of a flow-line divided by the net distance traversed; and formation factor was the electrical resistivity of a porous medium divided by the resistivity of the saturating liquid.

Wyllie and de Witte[5] have presented one of the several possible ways of showing that:

$$T = \varphi F \qquad (1)$$

is the only logical relation for models where the average volume of the pores is equal to their average length multiplied by their average cross-section. Equation (1) has been considered obvious by numerous investigators. However, it is not automatically correct for real systems, for which the value of T depends on the way the averages are taken. For example, in a randomly oriented set of straight uniform pores, the combination of their resistances in parallel shows that equation (1) holds with the harmonic mean of T and the arithmetical mean of the areas, while for a single pore of variable cross-section the reverse is approximately true.

Some rough calculations will serve to illustrate the chief characteristics. The geometry of 'flow-lines' accounts for both 'sinuosity' and 'convergence' of 'pores'[6]. Consider a conical segment expanding from radius a_1 to radius a_2, with straight flow-lines uniformly distributed. Let $r(x)$ be the distance of a flow-line from the axis; $r(0) = r_1$ and $r(L) = r_2$. Let θ be the angle between the flow-line and the axis; $\tan\ \theta = (r_2 - r_1)L$; $(a_2 - a_1)/L = \tan\Theta$, where Θ is the angle of the wall. For uniform distribution, $dr_2 = (a_2/a_1)dr_1$. Then:

$$\frac{1}{T} = \int_{\theta=0}^{\Theta} \cos^2\theta r dr \Big/ \int_{\theta=0}^{\Theta} r dr = \frac{(\log\ \sec.^2\Theta)}{\tan^2\Theta}$$

Now let δC be the total conductance of a sheath-shaped tube of flux between two conical surfaces : $\theta = \text{const.}$ and $\theta + \delta\theta = \text{const.}$

$$\frac{1}{\delta C} = \rho \int_0^L \frac{\mathrm{d}x/\cos\theta}{2\pi r.\cos\theta(\partial r/\partial\theta)\delta\theta}$$

where ρ is the fluid resistivity. The integration is performed by using the relation : $r = (x + a_1/\tan\Theta)\tan\theta$. The resulting expression is used to obtain the resistance of the whole segment :

$$R = 1/\int_{\theta=0}^{\Theta} \delta C = (\rho L \tan^2\Theta)/(\pi a_1 a_2 \log \sec^2\Theta)$$

Whence, for some arbitrary total area A :

$$T = (\pi a_1 a_2/A)F < \varphi F \qquad (2)$$

A measure of T independent of φ and F is possible, in principle, by such devices as transference lag[5] or transient diffusion[7,8]. If tortuosity is due mainly to pore 'sinuosity', and the arithmetical mean were measured, it might be that $T > \varphi F$, as the harmonic mean, appropriate for T in equation (1) for this case, is usually smaller. According to equation (2), the opposite would be expected when there are large variations of size in the pores.

Some authors have preferred to divest tortuosity of its geometrical significance and regard it simply as an impedance factor[9]. From this point of view, the tortuosity in the conical segment may be equated to φF, provided the corresponding approximation is made that the total resistance is the sum of the resistance of successive elementary segments in series. This familiar device amounts to assuming that flow-lines are geometrically parallel within each elementary segment. The result is :

$$T = (a_1^2 + a_1 a_2 + a_2^2)/3a_1 a_2 \qquad (3)$$

An analogous calculation for tortuosity in fluid-flow defines hydraulic resistance in terms of viscosity, η, as :

$$W = \frac{8\pi}{\eta} \int_0^L \mathrm{d}x/a^4$$

and a 'hydraulic formation factor', F_H, by :

$$W = \frac{F_H}{A} \int_0^L \frac{\mathrm{d}x}{\omega(x)}$$

where $\omega(x)$ is the average Poiseuille's-law mobility for the elementary segment at position x, given by :

$$\omega(x) = \int_0^a \omega(x,r) \frac{\mathrm{d}v}{\mathrm{d}r}\,\mathrm{d}r \Big/ \int_0^a \frac{\mathrm{d}v}{\mathrm{d}r}\,\mathrm{d}r$$

with

$$\omega(x,r) = (a^2 - r^2)/4\eta$$

$$v = \omega \mathrm{d}P/\mathrm{d}x$$

Integrating and combining :

$$F_H/A = (a_1^2 + a_1 a_2 + a_2^2)/3\pi a_1^2 a_2^2$$

which leads to :

$$\varphi F_H = [(a_1^2 + a_1 a_2 + a_2^2)/3a_1 a_2]^2 \qquad (4)$$

Equation (4) gives the square of the corresponding expression for electrical tortuosity in equation (3), but does not represent the geometrical tortuosity of the flow-lines. This provides a qualitative explanation for the fact that $(\varphi F)^2$ is the correlation function that has been derived from permeability experiments[1,10], while measured tortuosities have been close to φF in electrical migration and diffusion[5,8].

Proton Relaxation in Crude Oils

IT was shown by Gutowsky, Ray, Rutledge and Unterberger[1] that crude oils exhibit electron resonance and by Poindexter[2] that the Overhauser effect is found in crude oils. The existence of the Overhauser effect depends on at least a part of the relaxation of the protons being due to the free electrons. Because the electron resonance and Overhauser effect results vary from sample to sample, it seemed of interest to make proton relaxation measurements on a number of samples of crude oil. The proton relaxation in crude oils is also of interest because of the introduction of proton precession instruments for underground measurements in oil wells[3].

Thermal relaxation, viscosity and density data were obtained for twelve Texas and two California crude oils. Temperatures were varied from 3° C. to 100° C., and field strengths varied from about 0·02 gauss to 7,000 gauss. Detailed relaxation curves were obtained by use of a low-field free-precession apparatus. Care was taken that the oils did not change composition by evaporation between measurement of viscosity and sealing of samples in 'Pyrex' bottles for relaxation measurements. Signal decay, or transverse relaxation, curves also were obtained in the Earth's field.

Fig. 1 shows that relaxation time is closely correlated with viscosity, despite a great range of composition of crude oils even in the limited selection of fourteen samples, and despite a probable variability of free-electron content. Apparently, only a fairly small fraction of the proton relaxation is due to the free electrons in most oils. There was no striking correlation between relaxation time and density. The relaxation times that are plotted in Fig. 1 are the reciprocals of the initial slopes of the relaxation curves, that is, the reciprocals of the average relaxation-rates. These results are for relaxation at 15 gauss. It was noted that the variation of T_1 with temperature for any one oil has about the same slope on a log–log plot as the general trend shown in Fig. 1.

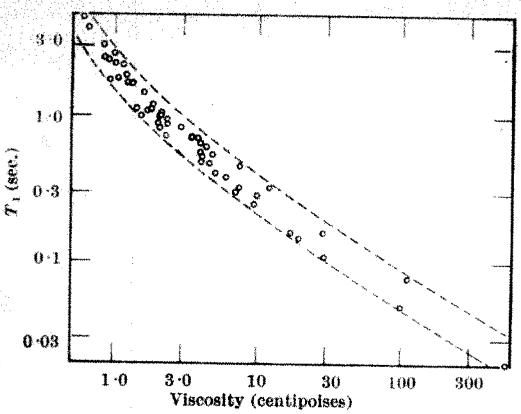

Fig. 1. Thermal relaxation times versus viscosity for 14 crude oils at various temperatures

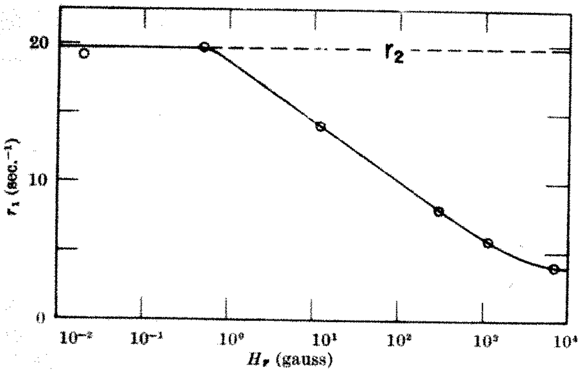

Fig. 2. Dependence of thermal relaxation-rate on magnetic field-strength for a crude oil sample

It was further noticed that there is no discontinuity at the 'pour point' for the oils exhibiting this phenomenon, although the macroscopic viscosity changes drastically as the temperature is lowered through this point.

Most of the crude oils showed a slight dependence on field for relaxation times, but only one sample exhibited strong dependence on field. The relaxation-rate (reciprocal of relaxation time) is shown as a function of field-strength in Fig. 2. At very low field-strengths, the thermal relaxation-rate is equal to the transverse relaxation-rate, which is indicated in Fig. 2 by the dashed line labelled r_2. Precession frequencies are presumably comparable to correlation frequencies in the range of field-strengths for which the relaxation-rate drops off with increasing field. If some of the relaxation is due to free electrons in the sample, it may well be that frequencies of electron precession are involved in the observed dependence on field.

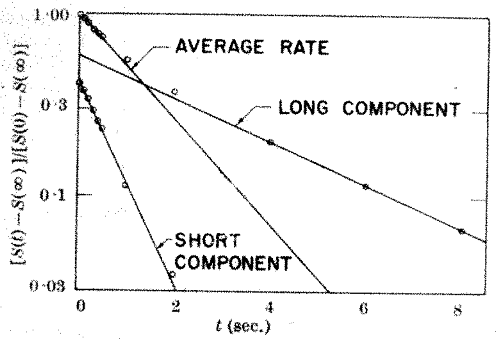

Fig. 3. Relaxation curve for a crude oil sample (different from sample represented in Fig. 2). S is the signal amplitude observed after allowing relaxation for a time t at the field for which relaxation data are desired

For all the oil samples the relaxation curves were noticeably non-exponential, and most of the curves can be represented within the accuracy of the data by the sum of two exponentials. In one of the samples there appeared to be an additional component of small amplitude and short relaxation time. The ratios of the pairs of relaxation times required to represent the relaxation curves varied from just over one to about five. The curves were carried out for relaxation by four powers of e in most cases. In many cases it was not possible to distinguish a curve composed of two distinct exponentials from a curve containing a distribution of relaxation-rates. Fig. 3 shows the relaxation curve for an oil for which the two relaxation-rates differ by a factor of nearly five. The curve labelled 'short component' shows the difference between the experimental points and the straight line labelled 'long component'. For this sample there appears to be two well-separated relaxation-rates.

BIOPHYSICS

Direct-Current Conductivity of Textiles, Proteins and Other Polymers

There has emerged from a recent study of the electrical conductivity of dry cytochrome c (ref. 1) an understanding of two properties of the conductivity of a variety of natural and synthetic polymers:

(1) The two commonly observed conductivity–sorption relations (1) and (2) (ref. 2) are expressions of one mechanism; namely, conduction by ions in a medium of very low dielectric constant:

$$\log \sigma = A.M + \text{const. (small } M) \quad (1)$$

$$\log \sigma = B.\log M + \text{const. (intermediate } M) \quad (2)$$

where σ is conductivity; M, moisture content; and A and B, constants characteristic of the material. It is also observed that A is in the range 0·1–1 for a variety of materials, and B, 6–16.

(2) That the activation energies of conduction for dry amorphous substances should commonly exceed 25 kcal. (1·1 eV.) (ref. 1) is also understandable in terms of the same mechanism.

The theoretical approach adopted in ref. 1 was first used by King and Medley[3] in studying the conductivity–sorption relations of keratin and nylon, water and formic acid. They had previously shown that in moist keratin the current carriers were ions[4]. Treating the system by Bjerrum's theory of weak electrolytes, the polymer being considered the solvent, they were able, using their measurements on the dielectric constant of the system, to calculate curves of the fraction of unpaired ions versus the sorbent concentration, which reasonably reproduced important features of the conductivity-sorption curves. The semiquantitative agreement confirmed their expectation that variation of the number of charge carriers had a greater effect on the conductivity than the variation of carrier mobility, but that the latter was not negligible. King and Medley's approach merits wider consideration.

To demonstrate point 1, one displays the dependence of the fraction of free ions (α) on the dielectric constant (D), using the expression for the pairing equilibrium, which Fuoss[5] gives as:

$$(1 - \alpha)/c\alpha^2 = (4\pi N_0 \alpha^3/3000)\exp[|Z_1 Z_2| e^2/aDkT] \tag{3}$$

(c is total concentration in moles/litre; N_0, Avogadros' number; a, the distance between the centres of the ions in the pair; the other symbols have their usual meaning). Under the conditions of low dielectric constant that exist in polymers, the fraction of free ions is so small that the α in $1 - \alpha$ may be neglected, permitting one to write:

$$\ln \alpha = -cK_0/2 - Q/2aDT \tag{4}$$

where K_0 and Q represent the known constants. If one substitutes for D the approximation $D = D_0 + \beta M$, and writes α_0 as the value of α for $M = 0$, one obtains:

$$\ln(\alpha/\alpha_0) = (Q/2aD_0T)\cdot[\beta M/(D_0 + \beta M)] \tag{5}$$

For M small enough $\ln \alpha$ is linear in M; this is the basis of equation (1). The constant A is approximately $Q\beta/2aD_0^2T$. Calculated values of A agree with the observed closer than by an order of magnitude.

It is a property of rectangular hyperbolas such as (5) that they give a sigmoid curve when plotted versus $\ln M$ instead of M. In the region of the inflexion point an expression of the form of equation (2) holds. The original approximation used for D is not valid for the larger values of M, but a new linear approximation can be used which is valid in the appropriate range of M. The slope of $\ln \alpha$ in equation (2) is then

$$B = Q/8a[D(M_1) - \gamma M_1]T \tag{6}$$

The calculated values of B also match the observed to within an order of magnitude. Thus the two observed conductivity–sorption relations are manifestations of the same mechanism: conduction by ions in a medium of very low dielectric constant.

The activation energy of conduction will be the sum of the activation energy of the carrier mobility and the enthalpy change of the pairing equilibrium. The latter is the larger. Differentiating equation (4) one gets:

$$\Delta H_a = R.(Q/2aD).[1 + T(\mathrm{dln}a/\mathrm{d}T + \mathrm{dln}D/\mathrm{d}T)] \tag{7}$$

As the temperature coefficient of a will be $\sim 10^{-4}$, the term $T(\mathrm{dln}a/\mathrm{d}T)$ may be neglected; however, as $\mathrm{dln}D/\mathrm{d}T \cong 3 \times 10^{-3}$ at high frequencies[6], $T(\mathrm{dln}D/\mathrm{d}T) \cong 1$ in the range 0–100° C. The appropriate values of D are less than 6. Using these values and 2·8 Å. for a, the Na—Cl distance in sodium chloride[7], one obtains as a least value of the activation energy of conduction, $E_a = \Delta H_a = 20$ kcal./mole.

As the high-frequency dielectric constant is probably the correct one to use, corresponding to the rapid motion of the free ions, values of $D < 6$ will always be found. For example, carefully dried oxidized cytochrome c at 10 cycles/sec. and 100° C. has a dielectric constant of 3·1 (ref. 1). The large values of activation energy found in dry substances are therefore understandable in terms of an ionic theory of conduction.

The success of an ionic mechanism treated by the approach of King and Medley[3] in explaining two commonly observed properties of polymeric materials suggests that the conductivity of dry protein[8,9] is not unique in being electronic, but is another case of ionic conduction in polymeric substances. While a mechanism of electronic conductivity has been used with success to explain some conductivity properties of irradiated polymers[10], the conclusion reached above is that the dark conductivity is ionic, and calls for a treatment of the irradiated system from the ionic point of view.

This work was done during the tenure of a Johnson Foundation predoctoral fellowship and was supported in part by the National Science Foundation.

GEOMORPHOLOGY

Involutions and Ice-Wedges in Devon

RELICT periglacial phenomena have been recorded from south-west England for more than two hundred years. Reference has been made to head, clitter, rubble drift, loessic deposits and other manifestations of mechanical rock-weathering and ablation of debris under sub-arctic conditions[1], to geomorphological features which resemble actively developing tundra land-forms[2] and to fossil floras with arctic or alpine characters[3]. But so far as has been ascertained, no account has been given of phenomena which attest to the former existence of frozen ground (tjäle) in Devon.

An instructive illustration of involutions[4] is provided by a disused 'gravel' pit in decomposed, hydrothermally altered (tourmalinized) granite at 1,380 ft. O.D. on the gently sloping (< 2°) Cowsic/Blackbrook interfluve 1 mile west of Two Bridges, Dartmoor (*SX*/596752). The pit sections show up to 2·0 m. of decomposed granite (growan) and head on an uneven base from which open-jointed masses of sound rock project tor-like into the incoherent material. The highly irregular boundary between the brown, gravelly and gritty head of relatively fresh crystal and rock fragments and the underlying, paler growan with its characteristic flecks of white, decomposed felspars is emphasized, in places, by a prominent 0·5-cm. thick iron pan, a product of post-periglacial pedogenesis. But the involutions are not confined to an interdigitation of head and growan.

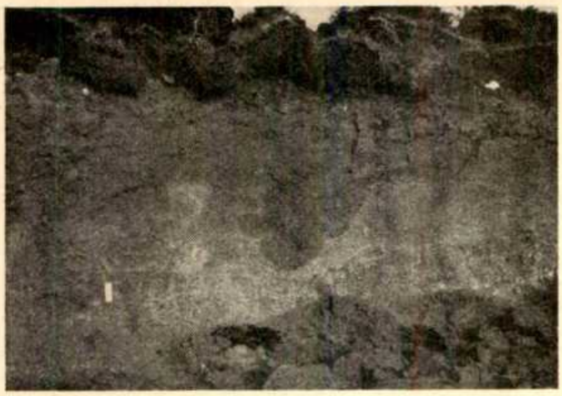

Fig. 1

Equally striking structures occur within the growan itself, which is disturbed to within 20 cm. of the base of the section (Fig. 1). A well-defined linear junction exists between the highly contorted growan characterized by a lineation of its altered felspars and the equally incoherent but undisturbed material in which the felspars have a random disposition as in adjacent blocks of sound granite. Thus it would appear that the lowest layer of the otherwise incompetent superficial mantle remained frozen while the overlying growan and head comprised an annual active layer or mollisol, and the involutions are expressions of the release of stresses set up during the re-freezing, from the surface downwards, of the seasonally thawed zone above the tjäle.

The example of ice-wedge pseudomorphs occurs in a pit at 450 ft. O.D. on the low western scarp of the Triassic Pebble Beds, 6 miles east of Cullompton (*ST*/066144). Unmistakable indications of frost-disturbance in the uppermost 1·0–2·0 m. of the pebble beds are provided by many exposures in the discontinuous escarpment, but it is reserved for the section in Fig. 2 to exhibit structures which are diagnostic of the former presence of the tjäle at such low elevations in Devon. The wedges penetrate up to 2·0 m. of the red, predominantly sandy, upper parts of the formation, the bedding of which is turned up sharply at their margins. They are filled with the same pale, yellowish sand that forms the bulk of the 60 cm. of head overlying the red rocks. It would seem that they were initiated as frost-cracks in frozen and thus impermeable sands and gravels, filled with melt-water from above, occupied by ice-wedges and afterwards filled with material washed in from the superjacent mollisol.

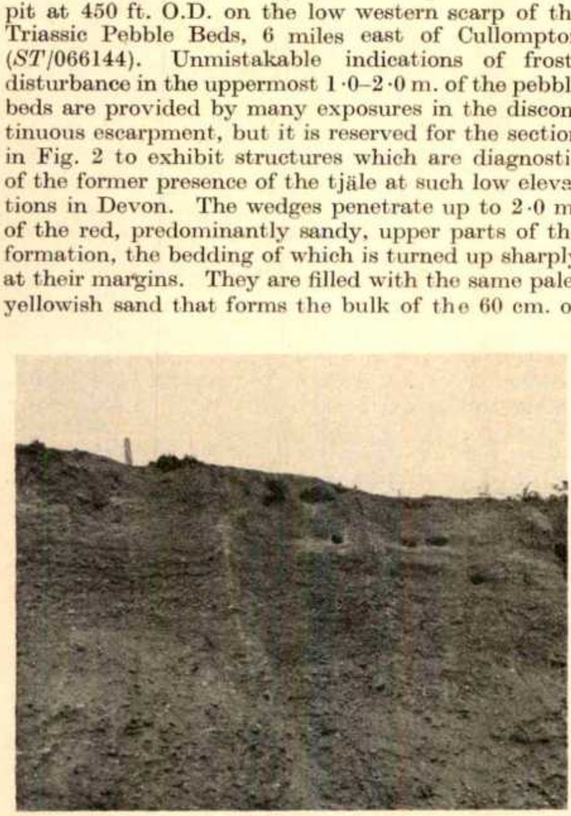

Fig. 2

A full account of these phenomena will be given elsewhere. But it may be noted that at least two distinct cryergic phases are represented at these and other sites. Thus we have evidence bearing not only on conditions during individual cold phases but also on the chronology of those Pleistocene phases during which the landscapes of south-west England experienced so profound a periglacial metamorphosis.

CRYSTALLOGRAPHY

Crystals of Cellulose

RECENTLY several authors have described the growth of polymer crystals from solution[1-5]. These crystals are lamellar in structure, and it has been established that the chain molecules are oriented perpendicular to the plane of the layers. Since the average chain-length considerably exceeds the thickness of the lamellæ, it has been proposed that the chain molecules must be sharply folded in the crystals[3]. In comparison with the synthetic polymers on which these observations have been made, cellulose molecules are known to be relatively inflexible and should therefore be an interesting system for similar studies. This communication gives a brief preliminary account of the growth of crystals of cellulose triacetate and their conversion to crystals of cellulose.

The cellulose triacetate used had a degree of polymerization of about 300 and an acetyl value of 44·3 per cent. The crystals were grown from solution in nitromethane with concentrations in the range 0·05–3 per cent. Crystallization was effected by supercooling the solutions. In the case of the more dilute solutions where the nucleation rate appears to be rather low, crystallization was facilitated by adding suitable amounts of a non-solvent to the solution.

The crystals were visible under the optical microscope with phase contrast or incident illumination (Fig. 1). They were square in shape, and electron microscopy has shown them to be lamellar in structure. X-ray and birefringence measurements suggest that the chain molecules are oriented normal to the plane of the lamellæ.

Deacetylation of the crystals was carried out in 2 per cent potassium hydroxide solution in aqueous methanol (50 : 50 v/v) at room temperature for about 10 hr.[6]. Following saponification, the material was washed thoroughly with water and examined in the optical microscope. The external form of the crystals was not disturbed by the reaction, although considerable shrinkage (about 30 per cent) in the lateral

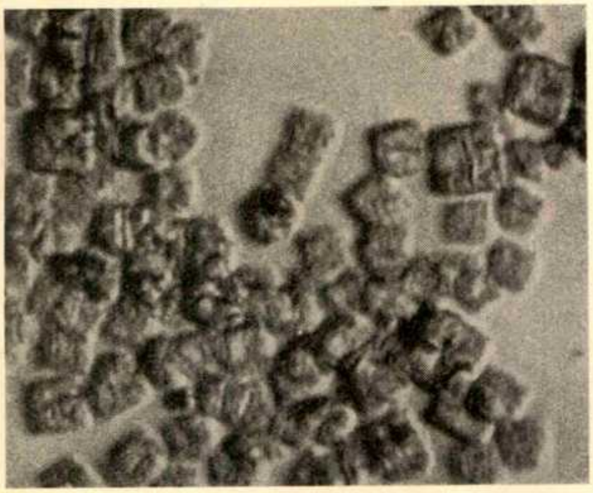

Fig. 1. Solution-grown crystals of cellulose triacetate (incident steep oblique illumination). (× 1,500)

dimensions had occurred. This contraction might possibly be accounted for on the basis of differences between the density and base molar weight of cellulose and the triacetate. The X-ray diagram (Fig. 2) of the deacetylated material shows it to have the structure of cellulose II, and indicates that the reaction had occurred throughout the lattice and not merely on the surfaces. Furthermore, optical birefringence indicates that the orientation of the chain molecules with respect to the layers was not disturbed by the deacetylation.

These observations suggest that, in spite of the relative stiffness of the molecules, folding similar to that observed in other polymers may also occur in cellulose.

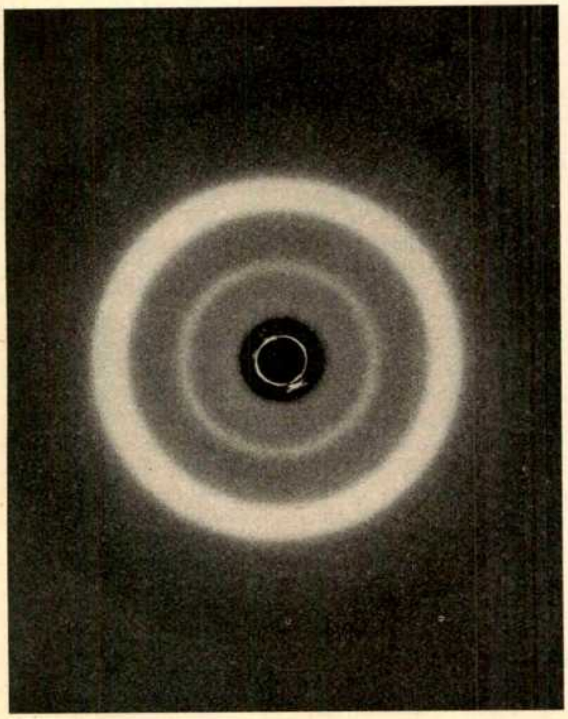

Fig. 2. X-ray diagram of deacetylated cellulose triacetate crystals

Detailed work on the morphology of these crystals is in progress and the results will be reported elsewhere.

CHEMISTRY

Determination of Heats of Adsorption by Transient-Response Techniques

The classical equations of chromatography[1] have been applied to the determination of the heat of adsorption of a gas on a solid[2,3] by recognizing that the measured residence time, within a packed column, of a pulse of adsorbable gas relative to that of the carrier (or non-adsorbable component) may be related to an 'equilibrium constant' K_a by the equation:

$$\frac{t_c}{t_a} = \frac{1}{1 + K_a} \quad (1)$$

where t_a and t_c represent the retention times, respectively, of the active and carrier species. By assuming that $K_a \gg 1$ and utilizing the usual temperature functionality for K_a, Greene and Pust[2] show that the logarithm of the retention time of the adsorbing component is linearly related to the reciprocal of the absolute temperature. Thus the observed data on retention time versus temperature permit the evaluation of the adsorption heat, ΔH. Good agreement between values of ΔH determined by this technique and those obtained by others calorimetrically and/or isosterically was found by Greene and Pust for the adsorption of some low boiling gases on charcoal and for light hydrocarbons on alumina and silica gel at temperatures below 100° C. However, these authors correctly noted that no simple correspondence should exist between heats of adsorption derived from continuous-flow transient-response data (adsorption chromatography in their work) and those obtained by calorimetric methods, since the latter are functions of surface coverage.

The purpose of this communication is to extend insight into the phenomenon by reviewing the fundamental equations which govern the pulse dispersion and its residence time for various well-known adsorption equilibria.

I shall consider the behaviour of a concentration pulse passing through a tube packed with solid particles capable of reversibly adsorbing the pulsed component. Travelling at an average velocity $u = u_0/f$, where f is the fractional void volume of the packed section, the pulse will be dispersed by virtue of axial diffusion[4] characterized by a coefficient, D, and by reason of equilibrium adsorption. In terms of column-length, x, one may write[5]:

$$D\frac{\partial^2 c}{\partial x^2} - u\frac{\partial c}{\partial x} = \frac{\partial c}{\partial t} + \frac{(1-f)}{f}\frac{\partial n}{\partial t} \qquad (2)$$

where $\partial n/\partial t$ represents the transient on the solid phase and $\partial c/\partial t$ that change resulting in the gas phase due to the adsorption–desorption process. In terms of the fractional surface coverage, θ:

$$n = n_0\theta = g(K_e, c) \qquad (3)$$

where n_0 is concentration of total adsorption sites, K_e is an adsorption equilibrium constant, $Be^{-\Delta H/RT}$.

A number of cases follow once the form of the equilibrium law is specified.

Case 1. *Simple Linear Equilibrium.*

$$n = n_0\theta = n_0K_ec \qquad (4)$$

Thus:

$$\frac{\partial n}{\partial t} = n_0\frac{\partial\theta}{\partial t} = n_0K_e\frac{\partial c}{\partial t}$$

Equation 2 becomes:

$$D\frac{\partial^2 c}{\partial x^2} - u\frac{\partial c}{\partial x} = \frac{\partial c}{\partial t}\left[1 + \frac{(1-f)}{f}K_e\right] \qquad (5)$$

Let:

$$\beta = 1/\left[1 + \frac{(1-f)}{f}K_e\right] \text{ and } Z = x - \beta ut$$

then:

$$\beta D\frac{\partial^2 c}{\partial Z^2} = \frac{\partial c}{\partial t} \qquad (6)$$

Equation 6 is readily solved[6] for the boundary conditions commensurate with a pulse input of volume V, to yield:

$$c(x,t) = \frac{V}{fA\sqrt{\pi\beta Dt}}\, e^{-[x-\beta ut]^2/4\beta Dt} \qquad (7)$$

where c is expressed as volume of active component per unit volume of fluid and A is the column cross-sectional area.

The mean retention time measured in terms of the pulse maximum is obtained by setting the first derivative of equation 7 equal to zero.

$$t_a = \frac{D}{\beta u^2}\left(\sqrt{1 + (xu/D)^2} - 1\right) \qquad (8)$$

When $xu/D \gg 1$ (a condition realized in beds of more than several particle diameters of length[6]), equation 8 becomes:

$$t_a = \frac{1}{\beta}\left[\frac{x}{u} - \frac{D}{u^2}\right] = \frac{t_c}{\beta} \qquad (9)$$

where the term $[x/u - D/u^2]$ is the retention time, t_c, of the carrier, since axial diffusivity, D, has been shown[6,7] to be independent of the nature of the gas so long as the Reynolds number (D_pu/υ) is greater than 10. At Reynolds numbers less than 10, differences in molecular diffusivity, D_m, exert a negligible effect if $D_m/ux \leqslant 0{\cdot}1$.

In the terminology of chromatography, therefore, equation 9 is, in terms of equation 1:

$$\beta = \frac{t_c}{t_a} = \frac{1}{1 + \frac{(1-f)}{f}K_e} = \frac{1}{1 + K_a} \qquad (10)$$

It may be concluded that isothermal residence-time data permit a determination of K_e when the linear equilibrium prevails.

Case 2. *Freundlich Equilibrium.*

Where:

$$n = n_0\theta = n_0K_ec^n \qquad (11)$$

Equation 2 becomes a non-linear one:

$$D\frac{\partial^2 c}{\partial x^2} - u\frac{\partial c}{\partial x} = \frac{\partial c}{\partial t}\left[1 + \left(\frac{1-f}{f}\right)K_enc^{n-1}\right] \qquad (12)$$

Measurements of β in this circumstance are of doubtful significance since the derived 'equilibrium constant', K_a in equation 1, is obviously a function of concentration distributed in a gaussian or near-gaussian fashion.

Case 3. *Langmuir Equilibrium.*

$$n = n_0\theta = \frac{n_0K_ec}{(1 + K_ec)} \qquad (13)$$

Equation 2 again becomes non-linear, the apparent β being:

$$\beta = \frac{1}{\left[1 + \frac{(1-f)}{f}(1-\theta)^2K_e\right]} \qquad (14)$$

The direct determination of K_a by equation 1 in this instance leads to meaningless results, since surface coverage is a variable dependent on both concentration and temperature.

We may conclude that only in the circumstance where a simple linear equilibrium law prevails will a meaningful value of K_a be inferred from transient–response studies. A pseudo-linearity of the adsorption isotherm may indeed be achieved by an appropriate choice of pulse concentration. Alternatively, the relationship between residence time and pulse concentration at a given temperature may be extrapolated to zero concentration[3]. However, should the condition of linear equilibrium be realized, the significance of the derived adsorption heats demands closer examination.

If, following Boudart[8], the heat of adsorption is expressed as a function of temperature by the approximation:

$$Q = q_0 + aT \qquad (15)$$

then, even in the instance of linear equilibrium, the logarithm of retention time versus reciprocal temperature relation becomes, in terms of K_a derived from 1:

$$\ln K_a = \ln B + a/R + q_0/RT \qquad (16)$$

Thus the heat of adsorption so derived is the minimum (q_0) corresponding to high coverage. This point is of great importance in the study of chemisorption of reactants on solid catalysts as the value of chemisorption heat derived by transient techniques will have little significance in catalysis.

Referring to equation 14, it is apparent that, where Langmuir equilibrium prevails and surface coverage varies only slightly with concentration, derived values of K_a versus temperature may yield an unusually low value of the heat of adsorption since the term $(1 - \theta)^2$ varies with temperature in a manner which will decrease the slope of a plot of $\ln K_a$ versus $1/T$ plot to yield a value of $q < q_0$.

I wish to acknowledge the benefits derived from discussions of this subject with Profs. Paul Emmett

and Richard Kokes of the Johns Hopkins University and Prof. Ralph Beebe of Amherst College.

Oxidation of Chromium(II) Amines by Water

AN interest in reactive reducing agents has led us to investigate aqueous solutions of chromium(II) containing excess of polyamines. We have observed that, in the absence of oxygen, these deep blue solutions (pH > 9) evolve hydrogen in accordance with the reaction:

$$2\mathrm{Cr(II)} + 2\mathrm{H_2O} \rightarrow 2\mathrm{Cr(III)} + \mathrm{H_2} + 2\mathrm{OH^-}$$

Although the reaction is quite slow when the amine is ethylenediamine or diethylenetriamine[1], with purified triethylenetetramine or *tris*(β-aminoethyl)amine[2] the reaction is sufficiently rapid to be studied conveniently. It is apparently autocatalytic with excess of the linear tetramine, and first-order in chromium(II) when the branched amine is present.

Hydrogen evolution from rapidly stirred solutions of chromium(II) perchlorate (0·02–0·05 M) in 0·3 M *tris*(β-aminoethyl)amine ($\mu = 1{\cdot}2$) was followed manometrically; it exhibited a strong dependence on pH. At 25°, the first-order rate constant was a maximum near pH 11 (4×10^{-4} sec.$^{-1}$) and lower by a factor of 10 at pH 9·5. No reaction was observable near pH 13. When all exchangeable hydrogen in reactants and solvent was replaced by deuterium, the rate constant was slightly decreased ($1{\cdot}0 \times 10^{-4}$ to $1{\cdot}3 \times 10^{-4}$ sec.$^{-1}$ at a glass electrode pH of 10·3). In isotopically normal media saturated with deuterium gas, the reaction did not yield measurable amounts of HD.

The other product of oxidation of chromium(II) by *tris*(β-aminoethyl)amine solutions, a violet chromium(III) complex, was subjected to chromatographic analysis on a column of 'Dowex 50 × 8' cation exchanger. Although it was slowly displaced as a single band by 0·01 M barium hydroxide, the complex could not be eluted by 0·01 N sodium hydroxide or, on the acid side, by N perchloric acid or 0·02 M lanthanum perchlorate in 0·01 N perchloric acid. This behaviour suggested that the oxidized chromium was bound as a binuclear complex carrying a charge of + 4 or more in acidic solution[3], until it was determined that *cis*-diaquo*bis*ethylenediamine cobalt(III) ion behaved similarly. The complex itself was isolated as the chloride by evaporation of the barium hydroxide eluate after precipitation of barium as the carbonate and subsequent acidification. This product had the same visible absorption spectrum as the reaction mixtures at complete reaction, maxima at 537 and 402 mμ, and gave chromium and nitrogen analyses indicating a ratio of chromium to *tris*(β-aminoethyl)amine of 1. The analytical results were not sufficiently precise to allow determination of a complete formula.

Although the observations detailed above do not suggest or rule out a mechanism for hydrogen evolution from aqueous chromium(II)–polyamine solutions, they are reported here since such evolution from homogeneous solution is uncommon.

A related observation, that chromium(II) added to a solution of *tris*(β-aminoethylamine) containing excess acrylamide is instantly oxidized to a complex different from that described, is still being investigated.

Polarographic Behaviour of Chromium-Dipyridyl Complexes

IT has been shown previously that dipyridyl (dipy) complexes of cobalt and nickel are reduced at the dropping-mercury electrode with the formation of uni- and zero-valent complexes, respectively[1,2]. Further work led to the conclusion that iron(II)-dipyridyl complex is not reduced at the dropping mercury electrode and that the complex $\mathrm{Mn(dipy)_3^{2+}}$ is reduced with the formation of manganese(I) complex (unpublished results).

The complex $\mathrm{Cr(dipy)_3^{3+}}$, prepared by Hein and Herzog's method[3], is reduced at the dropping-mercury electrode in three waves, the ratio of which is 1 : 1 : 1. The comparison with the wave-height of the complex $\mathrm{Cr(NH_3)_6^{3+}}$ has shown that each of the waves of $\mathrm{Cr(dipy)_3^{3+}}$ corresponds to the acceptance of one electron for each particle of the complex. In aqueous 0·5 M sodium chloride solution, the slope of the first wave is identical with that of a reversible one-electron wave. The second wave, on the other hand, has a discontinuous character and the third one is drawn out (Fig. 1). In a solution of lithium chloride in 50 per cent ethanol, the first and second waves have the shape of a reversible one-electron wave, but the third one shows a sharp beginning. Furthermore, a very small adsorption wave is observed in ethanolic solutions almost at the same potential as that at which the discontinuous wave in aqueous solution appears (Fig. 1). The half-wave potentials (measured against the saturated calomel electrode) are summarized in Table 1.

Table 1. HALF-WAVE POTENTIALS OF THE WAVES OF $\mathrm{CR(DIPY)_3^{3+}}$ (V., 20° C.)

Solution	First wave	Second wave	Third wave
0·5 M Sodium chloride, water	−0·36	−0·73*	−1·38
0·5 M Lithium chloride, 50 per cent ethanol	−0·36	−0·71†, −0·895	−1·35*

* Discontinuous wave. † Adsorption wave.

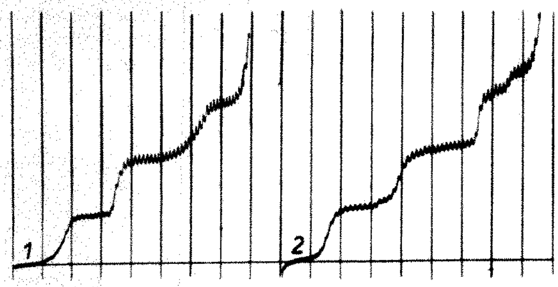

Fig. 1. The reduction of $Cr(dipy)_3^{3+}$. Curve 1, in 0·5 *M* sodium chloride (water). Curve 2, in 0·5 *M* lithium chloride, water–ethanol mixture, 1 : 1. Solution : 6 × 10^{-4} *M* $Cr(dipy)_3(ClO_4)_3$, from 0 V. (saturated calomel electrode), 200 mV. (absc.); nitrogen atm., *S* = 1 : 70

All three waves are diffusion currents. The addition of strong acids causes an increase of the second and third wave and the appearance of a kinetic, catalytic wave at negative potentials. This catalytic wave is formed even at very low hydrogen-ion concentrations, at which the increase of the second and third wave cannot be observed.

Using the Kalousek commutator, I have found that the product of the three-electron reduction is oxidized in three one-electron steps, the second and third being at the same potentials at which the reduction steps proceed. Similarly, the product of the two-electron reduction is reversibly oxidized in two steps and the product of the one-electron reduction in one step (Fig. 2). In experiments with the commutator in ethanol solution, the wave at − 0·71 V. is very pronounced, which is in agreement with its being an adsorption phenomenon.

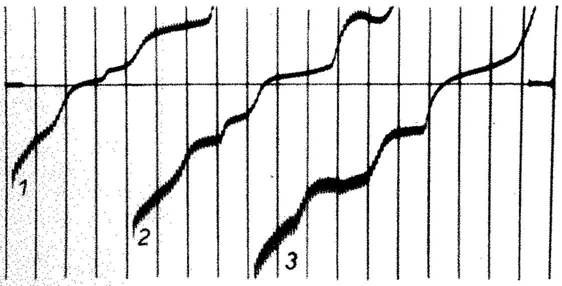

Fig. 2. Waves of complexes in lower oxidation states, generated by the commutator. Curve 1, wave of $Cr(dipy)_3^{2+}$, generated at 0·55 V. Curve 2, wave of $Cr(dipy)_3^{+}$, generated at −1·15 V. Curve 3, wave of $Cr(dipy)_3^{0}$, generated at −1·5 V. Solution: 6 × 10^{-4} *M* $Cr(dipy)_3(ClO_4)_3$, 0·5 *M* lithium chloride in ethanol-water mixture, 1 : 1 ; from 0 V. (saturated calomel electrode), 200 mV. (absc.) nitrogen atm., *S* = 1 : 150

The results described point to the conclusion that the complex $Cr(dipy)_3^{3+}$ is reduced in succession by one-electron steps, the final product being not metallic chromium but a complex of zero-valent chromium in solution which can be re-oxidized to the trivalent complex. The reversibility of the first reduction steps shows that the reduction proceeds without any change in the configuration of the complex, so that the following scheme can be written for the whole process :

$$\begin{array}{ccccccc} Cr(dipy)_3^{3+} & \rightleftharpoons & Cr(dipy)_3^{2+} & \rightleftharpoons & Cr(dipy)_3^{+} & \rightleftharpoons & Cr(dipy)_3^{0} \\ d_\varepsilon^3 & & d_\varepsilon^4 & & d_\varepsilon^5 & & d_\varepsilon^6 \end{array}$$

All complexes shown in the scheme have been prepared by Hein and Herzog[3], and their magnetic moments are in accordance with the electronic structure assigned by the letters d_ε.

The discontinuous shape of the waves is due to the formation of an insoluble reduction product. In aqueous solution the univalent and zero-valent complexes are insoluble, and hence the second wave is discontinuous. In ethanolic solution the univalent complex is soluble, but the solubility of the zero-valent complex is still very low, and accordingly the third wave has a discontinuous shape.

The first two reduction steps are reversible. The slight irreversibility of the third reduction step is probably due to the insolubility of the final product, the zero-valent complex.

The behaviour of the $Cr(dipy)_3^{3+}$ complex reported here is apparently the first known three-step reduction of a trivalent complex.

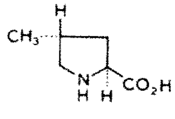
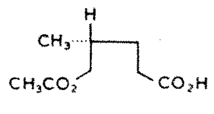
BIOCHEMISTRY

Absolute Configuration of 4-Methylproline from Perry

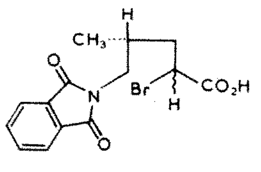
Two reports have appeared on the isolation of 4-methylproline from natural sources. Hulme and Arthington[1] isolated an amino-acid from apples, and tentatively assigned the structure of 4-methylproline to it as a result of elemental analysis, colour tests and chromatographic similarity to synthetic material. Later, two of us reported that hydrolysis of a peptide antibiotic yielded, *inter alia*, an amino-acid with the same chromatographic behaviour[2]. We have now been able to isolate 4-methylproline from perry (variety, Huffcap Seedling) by successive fractionation on 'Dowex-2' and 'Dowex-50' ion exchange resins. The crystalline amino-acid (8 mgm. from 5 litres of perry) has $[\alpha]_D$ *ca.* − 52° (*c.*, 0·3 in water), and is rigorously identified as *trans*-4-methyl-L-proline (I) by comparison with the optically active synthetic compound obtained as follows :



(I)



(II)



(III)

(+)-5-Acetoxy-4-methylpentanoic acid[3] (II) was converted by a mixture of sulphuric and hydrobromic acids to (−)-5-bromo-4-methylpentanoic acid, b.p. 114–18°/0·1 mm., the methyl ester of which, b.p. 96–100°/10 mm., condensed smoothly with potassium phthalimide to yield methyl (+)-4-methyl-

5-phthalimidopentanoate, m.p. 43–44°. Acidic hydrolysis of the methyl ester gave the acid, m.p. 73–74°, which was brominated with phosphorus and bromine to yield (+)-2-bromo-4-methyl-5-phthalimidopentanoic acid* (III), m.p. 141–42°. Vigorous acidic hydrolysis of the phthaloyl group and subsequent cyclization in aqueous sodium hydroxide furnished 4-methylproline*, m.p. 232–34° (dec.), $[\alpha]_D + 4$ to $+ 12°$ (in water, unchanged in 5 *N* hydrochloric acid). Separation of the *trans*-L-amino-acid was achieved through the solubility of its copper salt in absolute ethanol; decomposition of the copper salt with 'Dowex-50' (NH_4^+) cation exchange resin and recrystallization of the free amino-acid to constant optical rotation yielded *trans*-4-methyl-L-proline (I), m.p. 239–41° (dec.), $[\alpha]_D - 59°$ (*c.*, 0·3 in water), $[\alpha]_D - 32°$ (*c.*, 0·5 in 5 *N* hydrochloric acid). The positive shift in optical rotation on passing from neutral to acidic solutions establishes the L-configuration of the amino-acid[4]. Since (+)-5-acetoxy-4-methylpentanoic acid (II) has been converted to (−)-α-methylglutaric acid[5] of defined absolute configuration[6], the absolute configuration (I) of the synthetic 4-methylproline follows.

The infra-red spectra of the amino-acid from perry and the synthetic product (I) are virtually identical. Together with the correspondence in specific rotation, this establishes the absolute structure (I) for the natural amino-acid. It is noteworthy that the methylproline previously isolated from an antibiotic[2], although chromatographically indistinguishable from (I), has a quite different infra-red spectrum. In this connexion, isolation of the *cis*-4-methyl-D-proline diastereoisomer from the synthetic mixture is being attempted, and the results will be published elsewhere in the full account of this work.

As proline and glutamic acid are biogenetically related[7], it is likely that naturally occurring γ-methylglutamic acid[8] has the same configuration at $C_4(\gamma)$ as *trans*-4-methyl-L-proline, and hence may be accessible from the acetoxy-acid (II). Transformation of (II) into other methyl-substituted amino-acids is therefore being investigated.

We are grateful to Glaxo Laboratories, Ltd., for a generous supply of 5-acetoxy-4-methylpentanoic acid, and to the Department of Scientific and Industrial Research for a maintenance grant (to S. D.).

Molecular Properties of Conjugated Proteins isolated from Exudates

THE protein constitution of exudates and transudates has been dealt with in a previous paper[1]. It was observed that the most peculiar property is the occurrence in the exudates of conjugated proteins with well-defined physical and physico-chemical characteristics. It has also been shown[2] that these conjugated proteins are the basis of the positivity of the Rivalta test.

In this communication the results of a preliminary investigation on the molecular properties of the conjugated proteins isolated from exudates will be reported.

These substances were isolated by dialysis of the exudate against acetate buffer at *p*H 4·5, ionic strength 0·1. A few hours afterwards a precipitate appeared at the bottom of the dialysis bag, and the precipitation was complete after 12 hr. The precipitate was collected, redissolved in phosphate buffer at *p*H 7, and again dialysed against acetate buffer at *p*H 4·5. At the end of the dialysis the precipitate was collected and analysed in the electrophoresis. At *p*H 7 two components were present: the first, about 60 per cent, had a mobility of $\mu = 6\cdot2 \times 10^{-5}$ cm.^{2} sec.$^{-1}$V.$^{-1}$, the second, about 40 per cent, with a mobility $\mu = 4\cdot5 \times 10^{-5}$ cm.^{2} sec.$^{-1}$ V.$^{-1}$, similar to that of serum-albumin. By means of a separation cell the two components were separately collected, and only the first one, that is, the largest and fastest, was shown to possess an exudative character with high positivity of the Rivalta test. The sedimentation pattern (Fig. 1) revealed that this component behaves in the ultracentrifuge as a monodisperse system, and its sedimentation coefficient, extrapolated to zero protein concentration, is $S^0_{20} = 3\cdot7 \times 10^{-13}$.

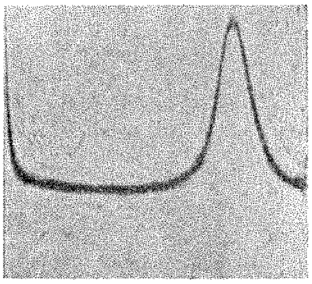

Fig. 1. 'Rivalta substance' isolated from serous exudate. Concentration: 1 per cent in phosphate buffer at *p*H 7. The photograph was taken 3·600 min. after reaching full speed of 59,780 r.p.m.

The diffusion constant calculated by the height/area method is $D^0_{20} = 2\cdot2 \times 10^{-7}$. Therefore, substituting in the Svedberg formula[3] the experimental values found for sedimentation, diffusion and partial specific volume ($\overline{V} = 0\cdot62$), the molecular weight was found to be $M = 108\cdot00$ and the frictional ratio $f/f^0 = 2$.

These results refer to a 'Rivalta substance' isolated from a serous exudate. In the case of other types of exudate, that is, hæmorrhagic or purulent, it has been observed that the molecular properties are somewhat different.

Research, now in progress, has provided clear evidence that several types of 'Rivalta substance' can be isolated, and, as previously stated, in any event there is a correlation between some biochemical aspects of the exudate and the type of inflammation.

Effect of Polylysine on the Absorption Spectrum of Hæmin

THIS is a preliminary report on a 'polybase effect' consisting of a considerable change in the spectrum of hæmin on its interaction with polylysine in alkaline solution. Two different types of complex are formed with poly-L-lysine which may be associated with the folded and unfolded structure of the peptide. These simple hæmin–polypeptide complexes are considered to serve as models for iron–porphyrin-containing enzymes, and it is hoped that they will add to our knowledge of the prosthetic group-protein interaction and of the catalytic properties connected with it.

The polybase effect on the spectrum of hæmin is illustrated in Fig. 1. (The hæmin was 6×10^{-5} *M* in this and in all other experiments reported here.) Curve 1 represents part of the visible-range spectrum of hæmin at *p*H 11, while curve 2 was obtained under identical conditions except for the presence of 6×10^{-3} monomolar poly-L-lysine (molecular weight of the order 5,000). It is evident that the polybase induces a drastic spectral change on hæmin. (Also the Soret peak of the interaction product lies at 420 mμ as compared to 385 mμ for hæmin.) The addition of L-lysine monomer of the same monomolar concentration as the poly-L-lysine to hæmin had little effect on the hæmin spectrum between 750 and 230 mμ. This polybase effect can be observed visually: when viewed in measuring flasks of 20–25 mm. diameter, the hæmin and L-lysine–hæmin solutions appear brown, while the poly-L-lysine–hæmin solution is red in colour.

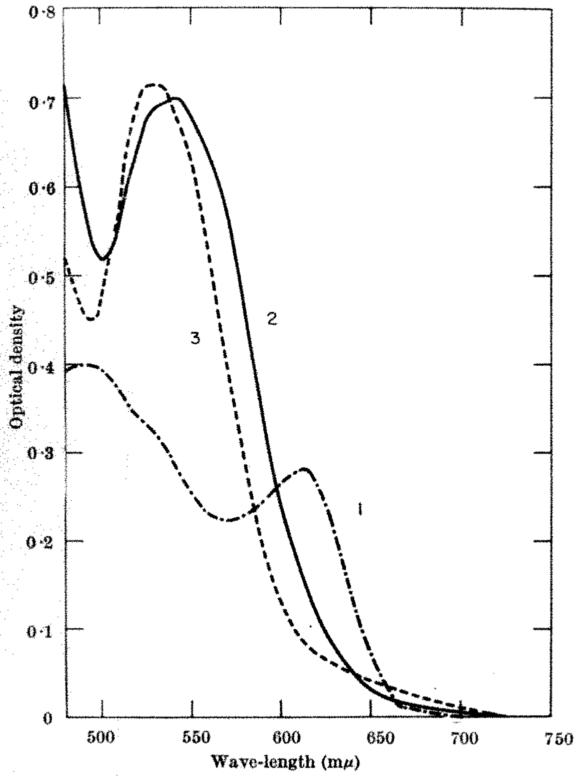

Fig. 1. Absorption spectra at *p*H 11. Curve 1, hæmin; curve 2, hæmin in the presence of poly-L-lysine; curve 3, ferricytochrome *c*

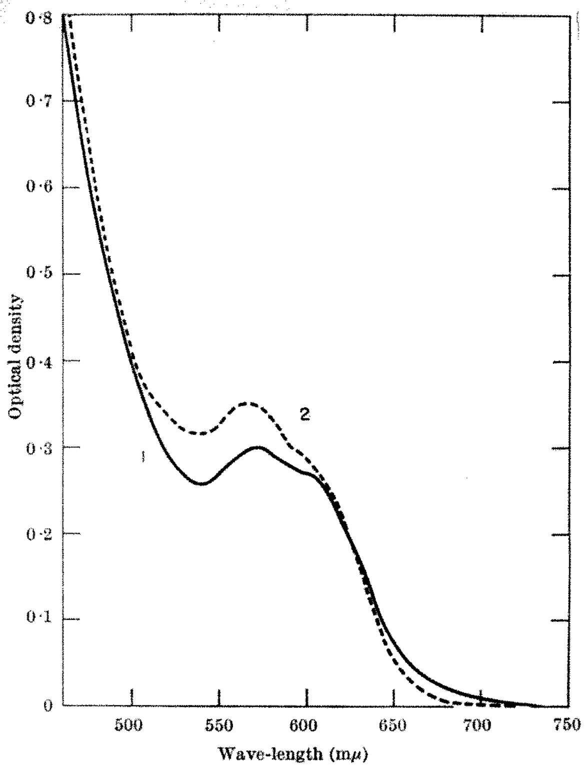

Fig. 2. Absorption spectra. Curve 1, poly-L-lysine : hæmin at *p*H 8–9 ; curve 2, poly-DL-lysine : hæmin at *p*H 11

On addition of hydrochloric acid to the red complex of poly-L-lysine with hæmin, the red colour changes to yellow-green at *p*H 9–10. Curve 1 of Fig. 2 is the measured absorption spectrum of this latter compound. Comparison with curve 2 in Fig. 1 confirms the drastic spectral change associated with this transition. (The Soret peak is at 388 mμ.) L-Lysine monomer of similar monomolar concentration again had no comparable effect on the spectrum of hæmin in the *p*H-region where the yellow-green complex is stable.

It has been shown[1] that poly-L-lysine in aqueous solution undergoes a pronounced change in optical rotation and other properties near *p*H 10. These changes have been correlated to a helix-coil transition occurring on decrease of *p*H. It would, therefore, seem reasonable to attribute the red complex described above to an interaction product of hæmin with some structurally ordered (helical) form of poly-L-lysine. Correspondingly, the yellow-green complex would be indicative of an unfolded peptide–hæmin interaction.

The following additional observations are believed to support these correlations: a sample of poly-DL-lysine of the same order of molecular weight and concentration as the poly-L-lysine used did not form the red colour with hæmin at *p*H 11, but instead showed the absorption characteristics of the yellow-green form which was obtained with poly-L-lysine at lower pH only (see curve 2, Fig. 2). This result is probably due to the formation of a random rather than a helical structure in the DL-copolymer. Moreover, a very low molecular weight poly-L-lysine of the order 600 at about the same monomolar concentration did not form a complex when mixed with hæmin at pH 11. Here, too, the absence of the red complex is probably due to the lack of suitable structure of the low molecular weight polypeptide. The folded form of the basic polypeptide apparently favours complete co-ordination to the hæmin by the basic groups of the side-chains.

The spectrum of ferricytochrome *c* from horse heart (about the same concentration in mgm./ml. as the poly-L-lysine) is shown for comparison in Fig. 1, curve 3. Though the spectra of the red poly-L-lysine–hæmin complex and that of ferricytochrome *c* are not identical—there appears to be a relative shift of about 10 mμ—it nevertheless seems possible to classify the cytochrome as a 'red complex' type. It would therefore be inferred that in ferricytochrome *c* the prosthetic group is bound to structurally ordered (helical) peptide over a wide range of pH-values (see refs. 2, 3 and 4).

It is obvious that the polylysine model compound described cannot be expected to conform in all respects to native ferricytochrome *c* and that it can only be considered to aid in our understanding of complex enzyme systems. We have found, incidentally, that poly-L-histidine forms a red hæmin complex similar to that of poly-L-lysine. Its region of stability is situated at lower pH than that of poly-L-lysine. In addition to a peak at 530–540 mμ there is a pronounced shoulder at 560 mμ. Poly-L-glutamic acid did not show any similar effect between pH 5 and 11·5.

A variety of physico-chemical methods has been employed during the past decades to determine the nature of the bonds involved in linking the prosthetic group to the protein in metal–porphyrin-containing enzymes, hæmoglobin and related compounds[4]. It is suggested that the differences in the spectra of the prosthetic group in these enzymes are conditioned not only by the different bond types but in some cases also by the secondary protein structure prevailing under the conditions examined. Thus the absorption spectrum of the prosthetic group–protein complex may serve as an indicator of the structural characteristics of the protein to which it is attached.

The effect of cyanide and similar small molecules acting as enzyme inhibitors on the spectrum of hæmin and of iron–porphyrin-containing enzymes is well known[4], and in many cases the spectra resemble those of the red complex obtained with poly-L-lysine and hæmin.

If the structural classification of the polylysine–hæmin complexes described above should prove to be correct, a simple and useful tool for identification and structural characterization of basic polypeptides and perhaps of other polybases may have been found which could yield valuable data down to low concentrations.

Further investigations by different physico-chemical methods including bivalent iron compounds and various polymers and copolymers are in progress. Details of the present work and studies of the catalytic properties of some of these compounds will be published in due course.

Thanks are due to the Department of Biophysics of the Weizmann Institute for the supply of various samples of polypeptides and for the determination of their molecular weight.

Glutamic Acid Formation by Transoximase–Oximase Reaction

It has been previously reported that there exist in various organisms two enzymes, named transoximase[1] and oximase[2], which catalyse the transfer and reduction of the oximino group respectively. In view of the fact that glutamic acid plays an essential part in amino-acid synthesis, we have now studied glutamate formation through the combined action of these enzymes.

The enzyme solution was prepared from fresh liver of a young cockerel mainly according to the procedures for preparation *A* described in our earlier work[3] on oximase. However, the fractionation with acetone was carried out at − 10° C., and 5 gm. of the last precipitate were dissolved in 25 ml. of water at 0° C. After dialysing against cold running water for 3 hr., the solution was mixed with 8 ml. of *M*/5 phosphate buffer of pH 7·0 and centrifuged at 5,000 r.p.m. for 7 min. at 2° C. The supernatant contains the apoenzyme of oximase as well as of transoximase.

To measure the enzymatic actions, the following reaction mixtures were made (Table 1).

Table 1. Compositions of Reaction Mixtures

Test No.	0·2 *M* α-keto-glutaric acid (ml.)	0·2 *M* acet-oxime (ml.)	0·004 per cent pyridoxal phosphate (ml.)	0·2 *M* phosphate buffer, pH 7 (ml.)	Enzyme solution (ml.)	Water (ml.)
1	0·5	0·5	0·5	0·5	2·0	0
2	0·5	0·5	0	0·5	2·0	0·5
3	0·5	0	0·5	0·5	2·0	0·5
4	0·5	0	0	0·5	2·0	1·0
5	0	0·5	0·5	0·5	2·0	0·5
6	0·5	0·5	0·5	0·5	2·0 (*B*)*	0

* Heated at 100° C. for 10 min.

After incubating the mixtures at 33° C. for 45 min., 1 ml. of 0·12 per cent hydrogenated diphosphopyridine nucleotide solution, 0·6 ml. of 0·01 per cent flavin adenine dinucleotide solution and 1 ml. of 0·2 *M* phosphate buffer of pH 7·5 were added to each of them. The last mixtures were then maintained at 33° C. for 1 hr. After the reaction, the mixtures were heated at 100° C. for 10 min., mixed with 0·1 ml. of glacial acetic acid and centrifuged at 10,000 r.p.m. for 20 min. at 2° C. 5 ml. of the supernatant were added to 2 ml. of aqueous suspensions of 'Dowex-50'. After standing at 20° C. for 10 min., the suspension was decanted three times by adding water and then centrifuged at 3,000 r.p.m. for 5 min. at 25° C. The sediment was mixed with 1 ml. of 2 per cent ammonia solution. After centrifuging at 3,000 r.p.m. for 7 min. at 25° C., the supernatant was chromatographed.

The pyridine coenzyme used was prepared by hydrogenating with alcohol dehydrogenase from yeast; its solution, therefore, contains the dehydrogenase and alcohol which cause the rehydrogenation of the coenzyme dehydrogenated during the reaction. The 'Dowex' employed was treated beforehand with 4 *N* hydrochloric acid and *N* sodium hydroxide in the usual way, and further with 2 per cent ammonia solution and 1 per cent hydrochloric acid. After washing with water, the resin was suspended in water.

To estimate the amount of glutamic acid formed, 0·05 ml. of the ammoniacal supernatant was spotted in a width of 15 mm. on a Tōyō No. 2 filter-paper and developed with a butanol–acetic acid–water (4 : 1 : 2) solvent. At the same time, a guide spot was made with a standard glutamate solution. The filter paper was then sprayed with a 0·2 per cent ninhydrin solution. The coloured portion corresponding to R_F 0·32 was cut off, extracted with 4·5 ml. of 75 per cent alcohol, and the absorption ($-\log T$) at 570 mμ was measured with a Hitachi-electric spectrophotometer. The total quantity of glutamic acid produced in each reaction mixture was calculated from a standard curve established under our experimental conditions (Table 2).

Table 2. Amount of Glutamic Acid produced

Test No.	1	2	3	4	5	6
Glutamic acid (mgm.)	1·17	0·78	0·62	0·52	0	0

The results obtained show clearly that glutamic acid is formed from acetoxime and α-ketoglutaric acid by the action of transoximase and oximase. It was observed in the control that the amount of α-ketoglutaric oxime produced by spontaneous transoximation[4] is less than the lowest limit which can be detected by this chromatographic method.

Replication of Deoxyribonucleic Acid in Non-dividing Bacteria

Deoxyribonucleic acid (DNA) is thought to be formed by replication. Meselson and Stahl[1] have used a density-gradient centrifugation technique to show that bacterial DNA is bipartite as was proposed by Watson and Crick[2] and that it reproduces in a semi-conservative fashion[3], each original sub-unit being found associated, on replication, with a newly formed sub-unit.

In the course of work on spontaneous mutation in non-dividing *Escherichia coli*, the possibility has been considered that errors may arise during DNA replication[4]. Although it is still a question whether such replication may account quantitatively for the mutations observed, it is clear that it does occur. Two systems of non-dividing *E. coli* have been employed in which there is a net increase of DNA but not of protein; they involve the starvation of histidineless auxotrophs for the amino-acid they require in the presence and absence of chloramphenicol.

E. coli 15 h^-(histidineless) were grown at 37° C. with shaking in a salts-glucose medium[5] to which $^{15}NH_4Cl$ was added as the sole source of nitrogen together with ^{14}N-L-histidine-hydrochloride (25 μgm. per ml.). Stationary phase cells which had ceased growth due to the exhaustion of glucose after 16-hr. incubation with shaking at 37° were harvested by centrifugation and washed twice with saline. These washed cells were transferred into nitrogen-14-salts-glucose medium with chloramphenicol (20 μgm. per ml.) but no histidine; aliquots were withdrawn at intervals up to 120 min. Estimations of DNA, RNA and protein were made by the diphenylamine, orcinol and Folin methods, respectively. As Table 1 shows, DNA increased by 79 per cent while RNA more than doubled; the change in the amount of protein was negligible and the number of viable cells remained constant.

Table 1. Synthesis of DNA, RNA and Protein of *E. coli* 15 h^- in a Histidine-Starvation Medium in the Presence of Chloramphenicol

Time of incubation (min.)	No. of viable cells (per ml.)	Relative amount per ml.		
		DNA	RNA	Protein
0	$3\cdot4 \times 10^8$	100	100	100
40	$3\cdot5 \times 10^8$	169	188	103
80	$3\cdot2 \times 10^8$	176	222	103
120	$3\cdot2 \times 10^8$	179	224	103

This DNA, formed in non-dividing cells without a concomitant net synthesis of protein, was investigated by the method of density-gradient centrifugation. The procedures for making the bacterial lysate by sodium dodecylsulphate and for centrifugation in a cæsium chloride solution were those described by Meselson and Stahl[1]. The ultra-violet absorption photographs of the equilibrated DNA (24 hr. at 44,770 r.p.m.) of the sample taken from the culture at 120 min. showed a well-defined ^{15}N–^{14}N hybrid DNA band together with a diminished ^{15}N–DNA band which had been observed as the sole band at zero time (Fig. 1).

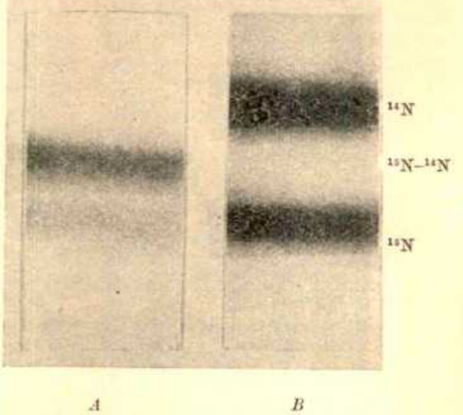

Fig. 1. Ultra-violet absorption photographs showing the DNA bands resulting from density-gradient centrifugation of: *A*, a lysate of *E. coli* 15 h^- labelled with nitrogen-15 taken after 120 min. incubation with chloramphenicol but no histidine in nitrogen-14 medium; *B*, a mixture of equal parts of lysates of *E. coli* 15 h^- labelled with nitrogen-15 and with nitrogen-14

A similar observation was made with *E. coli* 15 *t⁻h⁻*(thymine- and histidine-less). Cells labelled with nitrogen-15, grown in nitrogen-15-salts-glucose medium supplemented with ^{15}N-thymine (5 μgm. per ml., prepared from nitrogen-15-labelled cells of *E. coli* 15) and ^{14}N-L-histidine-hydrochloride (10 μgm. per ml.), were washed and transferred into nitrogen-14 medium with nitrogen-14-thymine, but no histidine, and incubated at 37° C. with shaking. After 120 min., DNA and RNA increased by 75 and 30 per cent, respectively, while the amount of protein and the viable cell number remained constant ($1{\cdot}5 \times 10^8$ per ml.)[6]. The sample taken after 120-min. incubation showed an intense ^{15}N–^{14}N hybrid band of DNA and a light ^{15}N–DNA band in the ultra-violet absorption photograph taken following density gradient centrifugation.

From these observations it is concluded that DNA formation involves replication in non-dividing, as well as in dividing, cells. This suggests the normality of the DNA formed without accompanying protein synthesis, which has been confirmed on biological grounds[7].

We are indebted to Prof. C. O. Beckmann of the Department of Chemistry, Columbia University, for his help with a Spinco *E* ultracentrifuge.

Bovine Submaxillary Mucin

A CONVENIENT method for the isolation of bovine submaxillary mucin in a relatively undegraded and homogeneous state compared to earlier methods[1] has been developed in this Laboratory. Fresh glands (640 gm.) were ground and stirred mechanically with three changes of 500 ml. of cold water for a total of 54 hr. The pooled extracts were clarified by centrifuging at 26,360*g* for 30 min. and adjusted to *p*H 3·5. The resulting mucin clot was separated and dissolved in cold water by neutralization to 7·5, and lyophilized. The product was purified by solution in 500 ml. of cold 50 per cent (w/v) aqueous calcium chloride. After centrifugation at 26,360*g* for 30 min., the supernatant was fractionated with cold ethanol. The fraction separating at 60–75 per cent (v/v) ethanol was collected by centrifugation at 26,360*g* for 30 min., dissolved in water, dialysed against water and lyophilized. All procedures were carried out at 0–4° C. The yield was 0·64 and 2·5 per cent of the glands on fresh and dry weight basis, respectively. The recovery of sialic acid was 36 and 60 per cent of that in the extract and mucin clot, respectively. A repetition of the procedure did not alter the composition of the product. The lyophilized powder could be stored at 2–4° C. without change of its properties.

The mucin was soluble in water and gave clear, colourless, viscous solutions. The solutions (0·5 per cent) gave single peaks on electrophoresis and ultracentrifugation at *p*H 7·4 and 11·3. The electrophoretic mobility was $-6{\cdot}7 \times 10^{-5}$ cm.^{2} sec.$^{-1}$ V.$^{-1}$ in phosphate buffer, *p*H 7·4 and ionic strength 0·1. The sedimentation constant ($S_{20,w}$) was 2·6 at 0·5 per cent in the same buffer. No decrease in relative viscosity was observed when that of the product was compared with that of the extract at the same concentration of sialic acid. The intrinsic viscosity of the product in phosphate buffer, *p*H 7·4 and ionic strength 0·1, was 13·4 dl./gm. The mucin contained 9·2 per cent nitrogen, 28 per cent sialic acid, 24 per cent hexosamine (as N-acetylgalactosamine), 2 per cent neutral sugars (as D-galactose), and 37 per cent protein. D-Galactose and L-fucose were the only neutral sugars detected on paper chromatograms. Tyrosine and sulphur-containing amino-acids were not found on the chromatograms.

The mucin (1 gm. in 200 ml.) at *p*H 7·4 was incubated at 37° C. with 50 mgm. of crystalline trypsin. A reduction of the viscosity to that of the solvent occurred within a few minutes. After 24 hr. the digest was dialysed with only a slight loss in protein. The tryptic digestion was repeated and the mucin was recovered from the digest by precipitation with ethanol in the presence of 5 per cent (w/v) calcium chloride. After a reprecipitation the final product was dissolved in water, dialysed, and then lyophilized. The yield was 80 per cent. Its electrophoretic pattern showed a single peak at *p*H 11·3 with unchanged mobility. It contained 8·7 per cent nitrogen, 31 per cent sialic acid, 27 per cent hexosamine, 2·5 per cent neutral sugars, and 32 per cent protein. The relative viscosity of a 0·5 per cent solution in phosphate buffer, *p*H 7·4 and ionic strength 0·1, was 1·16. These results indicate that the protein occupies an integral part of the mucin molecule and also is associated with its rheological characteristics.

An aqueous solution of the undigested mucin (1 per cent) was heated at 100° C. with hydrochloric acid. Nearly all the sialic acid became dialysable after treatment at *p*H 2·5 for 30 min., whereas practically no hexosamine was liberated. After 120 min., the hexosamine lost by dialysis was about 25 per cent, and no loss of protein was observed.

These results are compatible with one of the earlier structures proposed by Gottschalk[2] of a protein core surrounded with N-acetylgalactosamine units with all sialic acid as external end-groups.

This work has been supported by grants from the U.S. Public Health Service, National Institutes of Health (*USPH A*–1303, *A*–216, *A*–1225) and from the U.S. Army Medical Research and Development Board, Dental Branch (*ASG MD*–773 and 774).

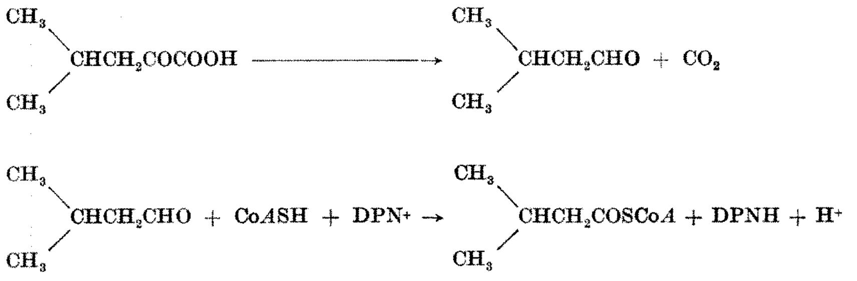
Degradative Pathway of L-Leucine in *Proteus vulgaris*

It was reported by Coon *et al.*[1–4] that in the metabolic pathway of L-leucine, *iso*valeryl coenzyme *A* was formed fromα -keto*iso*caproic acid, a deaminated product of leucine, in the presence of coenzyme *A* (Co*A*), etc. I postulate that this reaction involves the following two steps :



$$\underset{CH_3}{\overset{CH_3}{>}}CHCH_2COCOOH \longrightarrow \underset{CH_3}{\overset{CH_3}{>}}CHCH_2CHO + CO_2 \qquad (1)$$

$$\underset{CH_3}{\overset{CH_3}{>}}CHCH_2CHO + CoASH + DPN^+ \rightarrow \underset{CH_3}{\overset{CH_3}{>}}CHCH_2COSCoA + DPNH + H^+ \qquad (2)$$

In this communication it is reported that a cell-free extract which catalyses the reaction (1) was obtained from *Proteus vulgaris*.

Proteus vulgaris was cultivated at 37° C. for 18 hr. on peptone–broth agar slant. The cells were harvested, washed three times with de-ionized water, and suspended in 2×10^{-2} *M* phosphate buffer, *p*H 7·2. The washed cell suspension was disrupted by sonic oscillation in a Kubota vibrator, 10 kc./s., for 10 min. After centrifugation the supernatant was made 100 per cent saturated with respect to ammonium sulphate. The precipitate was dialysed against running water. In some cases, this dialysed protein solution was further fractionated with ammonium sulphate or cold acetone.

α-Keto*iso*caproic acid, used in the experiments, was prepared by extracting with acidic ether from the reaction mixture in which L-leucine was deaminated oxidatively by *P. vulgaris*. The melting point of the 2,4-dinitrophenylhydrazone of this keto-acid was 140–143° C. In this ether extract no other compound was detected by paper chromatography.

Carbon dioxide output was determined by the conventional Warburg method. The reaction mixture consisted of the following in a final volume of 2·5 ml. : $1{\cdot}67 \times 10^{-1}$ *M* acetate buffer at *p*H 5·0, 0·5 ml. ; 5×10^{-3} *M* magnesium sulphate, 0·25 ml. ; 2×10^{-1} *M* α-keto*iso*caproate, 0·125 ml. ; and enzyme, 1 mgm. protein. This reaction was carried out at 30° C. for 10 min.

The reaction of decarboxylation proceeded in nitrogen gas as well as in air ($Q_{CO_2}^{N_2}$ and $Q_{CO_2}^{Air}$ values were 1,158 and 1,207, respectively). The optimal *p*H was 5·0, and optimal substrate concentration was found to be 1×10^{-2} *M* ; half maximal activity was obtained with $1{\cdot}5 \times 10^{-3}$ *M*. Though it is not yet clear whether the reaction requires co-factors, coenzyme *A*, adenosine triphosphate, diphosphothiamine and Mg^{2+} were not required in the case of this crude enzyme.

Moreover, the reaction products were identified with paper chromatography. Three reaction systems were made as follows : (*a*) complete system (same as above experiments) ; (*b*) control system in which the enzyme was omitted ; and (*c*) control system in which the substrate was omitted. The volume of each reaction mixture was 10 ml. Immediately after incubation for 40 min. at 30° C., 0·5 ml. of mercuric acetate (5×10^{-1} *M*) was dropped in the reaction mixture. After the precipitate was discarded, 2,4-dinitrophenylhydrazine solution was added and stored at room temperature overnight. 2,4-Dinitrophenylhydrazone formed was washed thoroughly with hydrochloric acid, and dissolved with ether. The ether solution was used for paper chromatography. In experiment *c* no precipitate was formed. 2,4-Dinitrophenylhydrazone formed from experiments *a* and *b* and *iso*valeroaldehyde solution were developed with phenol (with 20 per cent water), *iso*amyl alcohol, and *n*-propyl alcohol as solvent, respectively. The results were represented in Table 1.

Table 1

Solvent	R_F value		
	Exp. *a*	Exp. *b*	Hydrazone of *iso*-valeroaldehyde
Phenol	1·00	0·81	1·00
*Iso*amyl alcohol	0·92	0·83	0·92
n-Propyl alcohol	0·91	0·82 ∼ 0·73	0·94

As shown in Table 1, one spot was obtained in experiment *a*, and the spot had the same R_F value of the hydrazone of *iso*valeroaldehyde. Furthermore, these spots were eluted from the paper with 15 per cent potassium hydroxide solution and were examined spectrophotometrically. It was concluded that *iso*valeroaldehyde was formed from this reaction system. The results reported in this communication and other experiments in which α-keto*iso*caproate was oxidized after vigorous decarboxylation, and reduced 2,6-dichlorophenolindophenol or methylene blue by this enzyme system in the presence of coenzyme *A* (and adenosine triphosphate and diphosphopyridine nucleotide), indicate that α-keto*iso*caproate was metabolized via *iso*valeroaldehyde (reaction (1)), and probably via reaction (2). Attempts at solving the latter reaction are in progress. Further details of this work will be published elsewhere.

I wish to thank Prof. S. Usami for his advice throughout the progress of this work.

N-Ethyl-L-Asparagine : a New Amino-Acid Amide from *Ecballium*

MANY new amino- and imino-acids have been identified recently as plant constituents. A number of these newer compounds can be regarded as derivatives of either glutamic acid or glutamine, in which substituents occur on the carboxyl, amino or amido groups, or on the β- or γ-carbon atoms. The related compounds, aspartic acid and asparagine, are not known to form an analogous, extensive range of substituted derivatives. Now, however, *N*-ethylasparagine has been isolated from *Ecballium elaterium* (the squirting cucumber). Its relationship to theanine (II), isolated by Sakato[1] from tea leaves, is seen below :

$$(C_2H_5)HNOC.CH_2.CH(NH_2).CO_2H$$
N-Ethyl-L-β-asparagine (I)

$$(C_2H_5)HNOC.CH_2.CH_2.CH(NH_2).CO_2H$$
N-Ethyl-L-γ-glutamine (II)

The new amide was first recognized as an unidentified, reddish-brown coloured spot (*U*, Fig. 1) present on a ninhydrin-treated, two-dimensional chromatogram of a 75 per cent (v/v) ethanol extract of the aerial portions of *Ecballium*. The amide gives a colour reaction with ninhydrin that is identical with that produced by asparagine under the same conditions. The compound occupies a position close to that of proline on two-dimensional paper chromatograms developed in phenol-ammonia, followed by *n*-butanol–acetic acid–water. The R_F in the latter solvent is very sensitive to variations in temperature ; at 10–15°, the amide has an R_{Alanine} value of about 1·2, whereas at 25–30°, the R_{Alanine} value may be as low as 0·92.

The amide was isolated from 4·5 kgm. of *Ecballium* material. The extract was first fractionated on cation-exchange resin columns ('Zeokarb 215' and 'Dowex 50') and then further purified by chromatography on washed sheets of Whatman No. 3 *MM* filter-paper. About 1 gm. of crude isolate was obtained, which gave 300 mgm. of chromatographically pure amide after recrystallization from 75 per cent (v/v) ethanol. The isolate had the following elementary analysis : C, 45·2 per cent ; H, 7·7 per cent ; N, 17·6 per cent. $C_6H_{12}N_2O_3$ (*N*-ethylasparagine) requires : C, 45·0 per cent ; H, 7·6 per cent ; N, 17·5 per cent.

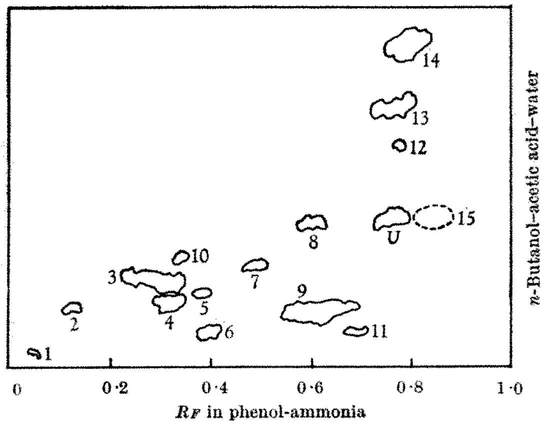

Fig. 1. Diagrammatic representation of a chromatogram prepared from an extract of *Ecballium*. The spots are : 1, cysteic acid ; 2, aspartic acid ; 3, glutamic acid ; 4, serine ; 5, glycine ; 6, asparagine ; 7, threonine ; 8, alanine ; 9, glutamine ; 10, α-aminoadipic acid ; 11, basic amino-acid ; 12, γ-aminobutyric acid ; 13, valine ; 14, leucines ; 15, position normally occupied by proline ; *U*, *N*-ethylasparagine

After hydrolysis with 6 *N* hydrochloric acid for 24 hr. at 100°, the amide was decomposed completely to yield aspartic acid and ethylamine hydrochloride. Assuming the structure (I), one mole of the isolate gave 0·96 mole of aspartic acid, and 0·98 mole of ethylamine. Aspartic acid was identified by comparison with an authentic sample by paper chromatography in four solvent systems (*n*-butanol–acetic acid–water mixture, 70 per cent (v/v) *n*-propanol, phenol-ammonia, and the upper phase of a mixture of ethyl acetate–pyridine–water, 2 : 1 : 2 parts by volume). Ethylamine, which was volatile in alkaline solution, was only chromatographed in the first two solvents and then as the hydrochloride.

The structure (I) was proved by comparison with synthetic material. After catalytic hydrogenation of N^2-benzyl-*N*-ethyl-DL-β-asparagine (kindly supplied by Dr. Liwschitz[2]), the main product, *N*-ethyl-DL-β-asparagine, was shown to be chromatographically identical with the isolated material in the above four solvent systems. The desired stereoisomer was prepared from L-aspartic acid, following the method of Hashizume[3]. β-Ethylaspartate, prepared by treating a suspension of aspartic acid in ethanol with dry hydrogen chloride at laboratory temperatures, was condensed with ethylamine, dissolved in a small quantity of ethanol, in a sealed tube at 100°. *N*-Ethyl-L-β-asparagine was separated from by-products by paper chromatography, and had the following analysis : C, 44·0 per cent ; H, 7·7 per cent ; N, 17·2 per cent.

The synthetic and isolated materials had the same melting point, 243° (decomp.), under identical conditions of very slow heating. The specific rotation in aqueous solution (*c*, 2·0 per cent) was also the same for both substances, $[\alpha]_D^{20°} - 5°$.

The natural and synthetic amides had infra-red spectra possessing identical absorption peaks (Fig. 2).

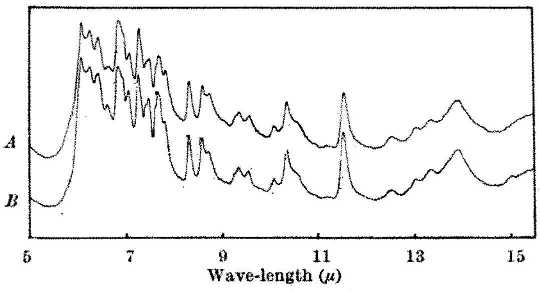

Fig. 2. The infra-red spectra of 'Nujol' mulls of *N*-ethyl-L-β-asparagine, (*A*) synthetic, (*B*) natural compound from *Ecballium*

The properties observed for the isolate confirm that it possesses structure (I) above, and so, more than 150 years after asparagine was first isolated from plant material[4], a naturally occurring derivative of the amide is now established.

Paper chromatographic evidence indicates that the amide is also present in the leaves of *Bryonia dioica* ; but it could not be detected in certain other Cucurbitaceae, including *Cucurbita pepo*, *Cucumis melo*, *Cucumis sativa* and *Echinocystis lobata*. An unknown spot (designated *U*131), observed in extracts of tulip leaves[5], moved to about the same position on paper chromatograms, and gave a similar reddish-brown colour after treatment with ninhydrin. Now it seems possible that this 'unknown' was *N*-ethylasparagine. It is interesting to recall that the concentrations of *U*131 and asparagine in tulip leaves, grown at different temperatures, showed a well-defined inverse correlation ; *U*131 was a more important constituent of leaves grown at 40° F., while asparagine was predominant in leaves grown at 70° F. Temperature could be affecting an equilibrium existing between asparagine and its *N*-ethyl derivative.

One of us (D. O. G.) wishes to acknowledge the receipt of an Agricultural Research Council postgraduate studentship during the course of this investigation.

PHYSIOLOGY

Release of Calcium-45 from Frog Nerves during Electrical Activity

Shanes and Bianchi[1] have demonstrated that stimulation of frog sartorius muscle accelerates the release of calcium-45 loaded on muscles, although Harris[2] had failed to observe this effect. Koketsu and Miyamoto[3] recently confirmed an increase in the output of calcium-45 during muscle activity. An important problem remains, however, whether acceleration of calcium output during activity is caused by the mechanism specific of the contractile system or actually is responsible for the electrical membrane phenomena. Hodgkin and Keynes[4] have reported that no change in calcium efflux can be detected during stimulation of squid axon, concluding that calcium movement during nervous activity is wholly inward. Furthermore, the 30-fold greater influx of calcium per impulse in muscle than in nerve despite the near equality of the resting influxes has been noted as consistent with a special role for calcium in contraction[5].

The experimental results reported here, however, clearly demonstrate that the release of calcium-45 loaded on nerve fibres apparently increases during electrical activity, suggesting that production of action potentials in muscles underlies the release of calcium at least in part. The discrepancy between the results observed with squid axon[4] and with the present material will be discussed at the end of this communication.

The present experiments were performed by using ventral- and dorsal-root nerves of bull-frog (*Rana catesbeiana*), which were dissected out together with the spinal ganglia and sciatic nerve plexus. These four preparations, isolated from a bull-frog, were tied together at the peripheral cut-end and suspended in a moist chamber. The root nerves were then immersed in Ringer's solution containing calcium-45 for 2 hr. at room temperature (24–26° C.). After washing the preparations for 20 sec. in Ringer, the time-course of the output of calcium-45 into normal Ringer was observed for 4 hr. During the procedure, the root nerves were successively immersed in a series of beakers containing 2 ml. Ringer every 20 min. Application of electrical stimulation (50/sec.) and recording of action potentials were made through electrodes placed on the sciatic nerves ; stimulation was applied for 40 min. during the 120–160 min. period after collection was started. The radioactivity of each collection, and the ashed root nerves, obtained at the end of the experiment, was measured. The rate coefficient curves[1] were constructed from these data.

Fig. 1 shows examples of the rate coefficient curves obtained from two experiments, to one of which stimulation was applied. The rate coefficient seems to settle within 120 min. to an almost constant value, so that it appears that the extracellular calcium-45 emerges within, at least, 120 min. and the slowly emerging calcium-45 is attributable to that coming from the axoplasma. The acceleration of output of calcium-45, induced by stimulation, therefore must be indicating an increase in the release of calcium from the nerve fibres. Presumably, the membrane calcium is removed during active depolarization by exchanging for external monovalent ions.

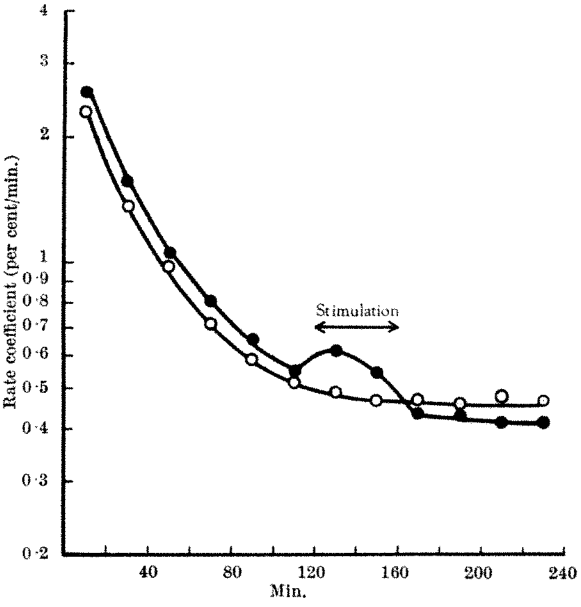

Fig. 1. Time-course of decline of rate coefficient of output of calcium-45 in Ringer. Two curves were obtained from two samples, to one of which stimulation was applied ; transitory rise in coefficients on application of stimulation is readily apparent

That the increased output of calcium-45 in squid axon was not observed[4] might have been due to technical factors. In most of these experiments, radiocalcium was injected into the axon for the purpose of excluding interference from the extracellular radioactive calcium and the efflux of this tracer calcium was observed. It seems that the efflux of intracellularly injected calcium-45 may be somewhat different from the calcium efflux observed in the present experiment, since (1) the method of application differs, and (2) the membrane calcium may easily exchange with the extracellularly applied calcium-45 but may not sufficiently with that applied intracellularly. It must also be kept in mind that the material differed from those used in the present experiment.

Significance of Membrane Calcium in Calcium-free and Potassium-rich Media

Frog Ranvier's nodes immersed in potassium-rich media are capable of producing action potentials when the membrane is hyperpolarized by anodal currents[1]. This observation was confirmed in frog sartorius muscles by one of us, who found that action potentials were restored by anodal polarization in frog sartorius muscles which depolarized in calcium-free media[2]. The so-called 'hyperpolarizing response' was also observed in muscle fibres soaked in both potassium-rich and calcium-free media. This experimental evidence seems to suggest that removal of calcium from the membrane in these two solutions might be responsible for the loss of membrane excitability, as suggested in a previous communication[2]. The rate of output of calcium-45 loaded on muscles, therefore, was studied in both calcium-free and potassium-rich solutions.

Isolated frog sartorius muscle was soaked in Ringer containing calcium-45 for 2 hr. at room temperature. After washing the muscles for 20 sec. in Ringer's solution, the time course of the output of calcium-45 into normal Ringer and the test solutions was observed for 4 hr. During this procedure, the muscle was transferred successively into beakers containing 2 c.c. Ringer every 3–20 min. for 2 hr., and the same procedure was continued for another 2 hr. using beakers containing test solutions. The radioactivity in each beaker and muscle was measured, and the time course of the output was plotted (Fig. 1).

The output of calcium-45 markedly increased when the solution was changed from Ringer to either calcium-free (particularly with ethylenediamine tetraacetic acid[3]) or potassium-rich (5–30 m*M*) Ringer[4] (Fig. 1). Such increase was precipitous and transient, suggesting the membrane phenomenon. Furthermore, the increase of the outflux was observed without detectable muscle contraction. The total amount of calcium was slightly, but apparently, reduced in these muscles (Miyamoto and Koketsu, unpublished work). If such loss of calcium is responsible for inexcitability and also for depolarization, reduction of membrane potentials in these two solutions would be less pronounced when the release of calcium is prevented in some way. Actually, no appreciable depolarization was observed when cocaine (8×10^{-4} gm./c.c.) was added to the calcium-free Ringer in which the release of calcium-45 was apparently inhibited as shown in Fig. 1. Similar results were obtained by adding magnesium[3], strontium, cobalt, or nickel ions to the calcium-free solution. Depolarization in potassium-rich solution could also be prevented by increasing the external calcium or adding these divalent cations; the increased release of calcium-45 observed in potassium-rich solution was inhibited in these cases. Similar results were also obtained by adding cocaine (1×10^{-3} gm./c.c.) to the potassium-rich solution (Fig. 1). These experiments demonstrated clearly the close parallelism between the drop of resting potential and the output of calcium-45 in both calcium-free and potassium-rich solutions.

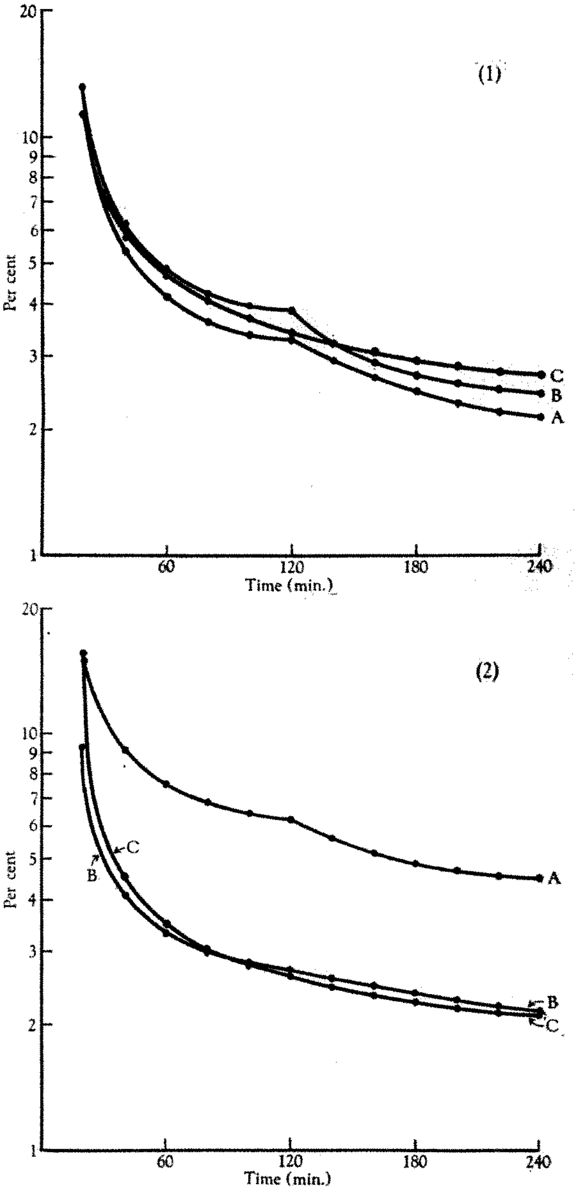

Fig. 1. Time-course of decline of calcium-45 content of individual muscles. Time-course during initial 120 min. was obtained in Ringer. After 120 min. bathing solutions were changed to test solutions: (1) *A*, calcium-free Ringer; *B*, calcium-free ethylenediamine tetraacetic acid (4 m*M*) Ringer; *C*, calcium-free Ringer containing cocaine (8×10^{-3} gm./c.c.). (2) *A*, potassium-rich (20 m*M*) Ringer; *B*, potassium-rich Ringer containing 50 m*M* calcium chloride; *C*, potassium-rich Ringer containing cocaine (1×10^{-3} gm./c.c.)

The observation[4] that the efflux of radiocalcium increases during muscle activity has been confirmed by us. The problem whether removal of calcium is consequential[4] or actually the cause of depolarization, in calcium-free and potassium-rich media or during stimulation, seems to be crucial.

Rapid Reduction of Portal Blood Ammonia

Ammonia is a normal constituent of portal blood[1], the concentration in the mesenteric veins draining the distal portion of the small intestine, cæcum, and upper colon being 50 per cent higher than that in the peripheral circulation[2]. Most of the ammonia in the body is produced as a consequence of bacterial action on nitrogenous substrates within the intestine[2]. Investigations with isotopically labelled urea in several species of animals have revealed that urea is hydrolysed in the alimentary tract, even when administered parenterally[3], and, in man, 0·3 gm. of urea is hydrolysed per hour, and 15–30 per cent of the urea synthesized in normal subjects is continually being destroyed[4].

Attempts to lower the ammonia concentration of peripheral blood with antibacterial agents has yielded contradictory results. No change was found in the peripheral blood ammonia in dogs treated with oxytetracycline or neomycin[5,6]. In these experiments the initial values in peripheral blood were too low to reflect any change which might be due to the antibiotics.

Oxytetracycline, but not neomycin, lowered the blood ammonia concentration in the mesenteric vein of rabbits[7]. Dogs fed uncooked horsemeat for three days exhibited marked reductions in portal blood ammonia following medication with 6 gm. neomycin; sulphasuxidine and achromycin were much less effective[8]. This variation in response is believed due to the differences in flora found in herbivores and carnivores.

The present work is concerned with rapid reductions in portal blood ammonia following administration of an intravenous combiotic to hyperammonæmic dogs, together with evidence of an *in vivo* reduction of the intestinal bacterial population during the medication period.

Forty mongrel dogs, clinically free of disease and weighing 8–10 kgm., were fed 700 gm. raw horsemeat daily for 5 days. Medication was as follows: (1) medication in diet; (*a*) 50,000 units *K* penicillin + 25 mgm. streptomycin daily for 5 days; (2) medication after laparotomy; (*b*) 60 ml. saline, (*c*) 50,000 units *K* penicillin, (*d*) 25 mgm. streptomycin and (*e*) 50,000 units *K* penicillin and 25 mgm. streptomycin. Medications given after laparotomy were contained in 60 ml. saline, and infused into the cephalic vein at the rate of 2 ml. per min.

Laparotomies were performed under pentobarbital anæsthesia, and the caudal mesenteric vein leading from the descending colon exposed. Blood samples were withdrawn into heparinized syringes from the mesenteric and cephalic veins, prior to, and 2, 4 and 8 hr. after medication. Blood samples were obtained in a similar manner from dogs receiving antibiotics in their diet; in addition, samples were obtained at 24-hr. intervals for 5 days. Blood ammonia and urea nitrogen were determined by the microdiffusion methods of Conway[9].

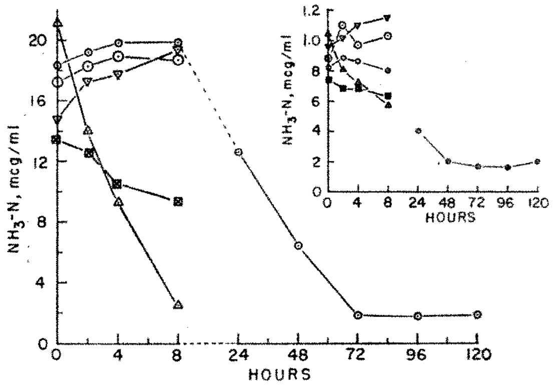

Fig. 1. Portal and peripheral blood ammonia 2, 4 and 8 hr. following intravenous medication with saline (○), streptomycin (⊠), penicillin (▽) and penicillin + streptomycin (△), or dietary supplementation with penicillin + streptomycin (○) over a 5-day interval. Each point on the graph represents the mean value for 8 dogs. Lower graph, portal blood ammonia; upper graph, peripheral blood ammonia

Fig. 1 shows the blood ammonia concentration, and Fig. 2 the blood urea nitrogen concentration, in portal blood 0, 2, 4 and 8 hr. after medication, and in the case of dogs with combiotic in the diet at 24, 48, 72, 96 and 120 hr. after medication. On each figure are superimposed the respective peripheral blood values obtained. The advantage of using penicillin and streptomycin together lies in their synergistic action when employed in combination[10,11]. Orally administered, non-absorbable antibiotics reduce the peripheral blood ammonia in hepatic coma[12] and cirrhosis of the liver[13] only after a 1–2-day interval. The need to lessen rapidly the ammonia load on the liver, thereby keeping the tricarboxylic acid-cycle functional, makes a slow-acting agent less than optimal. The results presented here demonstrate the value of using a combination of antibiotics which act synergistically and bring about a reduction in both the peripheral and portal blood ammonia within 4–8 hr. following administration.

A combination of penicillin and streptomycin reduces markedly the numbers of viable enterococci

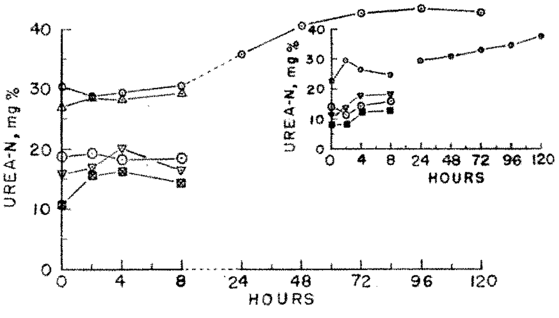

Fig. 2. Portal and peripheral blood urea nitrogen 2, 4 and 8 hr. following intravenous medication with saline (○), streptomycin (▽), penicillin (⊠) and penicillin + streptomycin (△), or dietary supplementation with penicillin + streptomycin (○). Each point on the graph represents the mean value for 8 dogs. Lower graph, portal blood urea nitrogen; upper graph, peripheral blood urea nitrogen

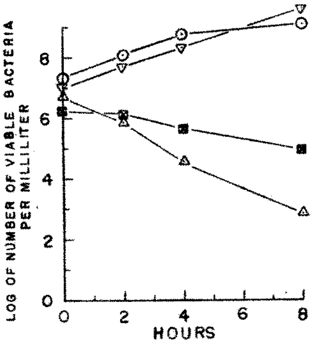

Fig. 3. Change in numbers of viable enterococci 2, 4 and 8 hr. following intravenous medication with saline (○), streptomycin (▽), penicillin (⊠), penicillin + streptomycin (△). Dilutions of fæcal aspirate were such that each ml. of broth contained the organisms from 1 gm. of fæces

in vitro[11]; however, this has not been demonstrated to occur rapidly *in vivo*. In the present work a sample of fæces was removed from the descending colon adjacent to the area from which the blood samples were obtained for cultures in McConkey's medium. Fig. 3 shows the changes in enterococci population at intervals corresponding to those when blood samples were obtained. It is readily seen that the reduction in blood ammonia and urea nitrogen parallels the reduction in number of viable intraluminal bacteria.

Part of this work was carried out while we were assigned to the U.S. Army Medical Research and Nutrition Laboratory, Denver, Colorado. We wish to acknowledge our indebtedness to Major R. O. Linder for performing the surgical operations.

Effect of Phentolamine on Body Fat

SEVERAL recent publications have described an increase in the level of non-esterified fatty acids in the plasma of dogs or human beings after administration of certain adrenergic blocking agents. This effect has been observed in dogs injected with dibenamine[1] and dibenzyline[2] and in human beings treated with phentolamine[3].

Work in our Laboratories with phentolamine (phentolamine hydrochloride, 'Regitine^R' hydrochloride, kindly supplied by Dr. F. Yonkman, Ciba Pharmaceutical Products, Inc.), several other imidazoles and related structures has shown these drugs to have an action in reducing the rate of gain in weight of the *in situ* epididymal fat bodies of immature male rats. The drugs were administered subcutaneously twice daily for a 7-day treatment period to groups of six rats weighing 55–56 gm. Rats in a control group were injected with vehicle only. Change in body-weight and food consumption were determined daily. The fresh weight of the epididymal fat bodies was determined on the morning of the eighth day. Phentolamine administered at 4, 8 and 16 mgm./kgm. doses significantly decreased the fresh weight of the fat bodies by 16, 24 and 28 per cent, respectively ($P < 0\cdot05$), but did not significantly depress daily food consumption or gain in body-weight compared to control values. In other experiments daily food consumption was occasionally depressed.

Extension of this work led us to examine the effect of phentolamine on the extractable lipid of the carcass and adipose tissue. Three groups of five male rats weighing about 100 gm. at initiation of treatment were used. A control group was given carboxymethylcellulose vehicle (CMC) subcutaneously twice daily for a 2-week treatment period. A second group received 4 mgm./kgm. of phentolamine twice daily for 2 weeks. A third group was pair fed with the phentolamine group and received vehicle injections as in the first group. The day following the 2-week treatment period the rats were killed and the fresh weight and lipid content of the adipose tissue depots determined. Extractable lipid of the trimmed carcass was also measured. Lipid extractions were performed with chloroform/methanol (2 : 1). The results are shown in Table 1. The phentolamine-treated group showed significantly less total extractable lipid from carcass and epididymal fat bodies than either the control or pair-fed groups. The remaining intraperitoneal fat appeared to decrease in quantity but did not differ significantly from control values. Liver lipid content of phentolamine-treated rats did

Table 1. EFFECT OF PHENTOLAMINE ON CARCASS AND ADIPOSE TISSUE LIPIDS

† Mean ± *S.E.* for 5 rats.

‡ Significantly different from the full-fed control group ($P < 0\cdot05$).

§ Includes lipid of the carcass, epididymal fat bodies and intraperitoneal adipose tissue.

not differ significantly from control (results not shown).

The extractable lipids of the carcass were further characterized by separation into saponifiable and non-saponifiable fractions. The saponifiable fractions contained $80 \cdot 5 \pm 4 \cdot 0$, $56 \cdot 9 \pm 3 \cdot 3$ and $75 \cdot 2 \pm 2 \cdot 3$ per cent of the total lipids for the full fed, phentolamine-treated and pair-fed groups, respectively. The significant decrease in concentration of saponifiable lipids of the phentolamine group suggests that neutral triglycerides are most labile.

We have also observed in preliminary experiments (Fig. 1) that the plasma concentration of non-esterified fatty acids in groups of rats treated for 1 week with phentolamine was significantly increased. This increase was greatest on the day treatment was initiated and tended to fall to control-levels from the second to seventh days. In phentolamine-treated rats the level of non-esterified fatty acids in the plasma was significantly greater than control on days 0, 2 and 4. The gain in fresh weight of the epididymal fat bodies was most depressed during the first few days after which the rate of increase in weight paralleled that of control animals. The weight of the fat bodies was significantly ($P < 0 \cdot 05$) less than control on days 2, 4 and 7.

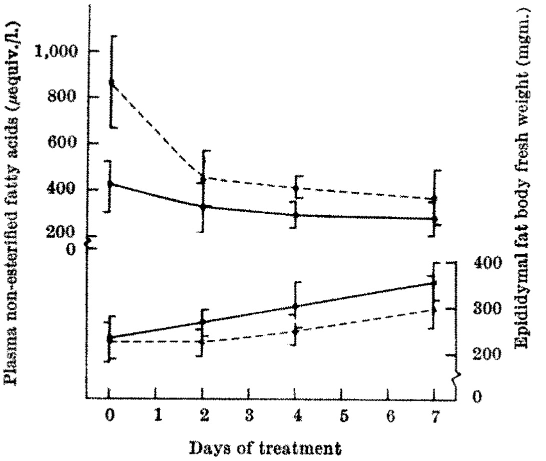

Fig. 1. Effect of phentolamine on plasma non-esterified fatty acids and the fresh weight of the epididymal fat bodies during 1 week of treatment. Determinations were made 2 hr. following the morning dose of drug on days 0, 2, 4 and 7 (6 rats per group). - - -, Phentolamine (8 mgm./kgm. twice daily); ——, control. [, 95 per cent confidence label

If phentolamine is acting to produce its effect on body-fat by some action on the autonomic nervous system, then it is possible that the observed results are secondary to catecholamine release either from the adrenal medulla or sympathetic nerve endings. Epinephrine does not appear to be implicated, however, since little or no change in blood glucose-levels has been observed by Klein and Bogdonoff[3] in humans or in our Laboratories (unpublished results) in rats. It is of interest to note that parenteral administration of phentolamine in man increased plasma norepinephrine- but not epinephrine-levels[4]. Norepinephrine increases plasma concentration of non-esterified fatty acids in man[5] and in dogs[6]. In addition, we have been successful in producing a depression of the fresh weight of the epididymal fat bodies with norepinephrine in oil using subcutaneous doses of 0·5–1·0 mgm./kgm. twice daily for 7 days. Experiments are in progress to determine the effect of phentolamine on the fresh weight of the epididymal fat bodies in adrenalectomized rats and on urinary catecholamine excretion.

Liver and Depot Fatty Acids in Kwashiorkor

Two of the clinical features of the malnutritional state seen in tropical children and known as kwashiorkor are the marked increase of fat in the liver and the presence of depot fat in usual amounts. As the diet leading to this condition is poor in protein and fat, and contains relatively large amounts of carbohydrate, it was hoped that a study of the composition of the liver lipid might lead to a clearer understanding of the origin of this lipid. Earlier work[1] on the phospholipid, non-saponifiable and fatty acid fractions of the liver lipid in kwashiorkor showed that their proportions and degree of unsaturation were not the same as in excess liver lipid found in children who were apparently well nourished but suffering from other diseases.

To find out if the fatty acid composition of the liver lipid was also different in kwashiorkor from that in fatty livers due to other causes (control series) the lipid from post-mortem portions of liver from children aged 1–4 years was extracted with petroleum ether and the acids obtained by hydrolysis of the lipid were examined by gas chromatography. The results (mean values and *S.E.*) can be seen in Table 1, where comparable results from a similar examination of the depot fat can also be seen.

The findings are as follows: (1) There is a greater proportion of C_{18} unsaturated ($C_{18} : \Delta$) fatty acids in liver lipid in kwashiorkor. (2) There is no correlation between the proportion of $C_{18} : \Delta$ acids in the liver and the amount (gm./100 gm. liver) of liver lipid. (3) The kwashiorkor depot fat C_{14} and C_{16} acids are reduced and $C_{18} : \Delta$ fatty acids are increased. (4) No correlation exists between the portions of the various fatty acids in the depot fat and the amount of liver lipid. (5) In controls the proportions of fatty acids in the liver differ from those in the depot fat. (6) In kwashiorkor the liver lipid fatty acid com-

Liver Control	Trace	4·9 ± 0·10	39·7 ± 2·26	43·5 ± 1·66	11·9 ± 1·28	11
Depot Kwashiorkor	2·9 ± 1·11	[8·3] ± 2·61	[30·0] ± 5·57	[51·6] ± 4·79	7·3 ± 0·81	4
Depot Control	7·9 ± 1·67	15·8 ± 1·73	44·9 ± 2·87	26·4 ± 2·80	5·1 ± 0·98	7

(Figures in square brackets indicate that when compared with control $P = < 0·05$.)

position is very similar to that in the depots. (7) The proportions of fatty acids in the depot fat in kwashiorkor are very similar to those described in the European adult[2,3].

From these preliminary observations it seems that the fatty acid composition of the liver lipid in kwashiorkor is different from that in other types of fatty liver found in comparable children. Also in kwashiorkor the proportions of the fatty acids in the liver fat are very similar to those in the depot fat, and these in turn are very similar to values given for depot fat of normal European adults.

One of us (I. M.) wishes to thank the Ciba Foundation and Institut National d'Hygiène, Paris, for a grant enabling him to work in French West Africa.

Relations of Intensity of Photosynthesis and Appearance of *Piricularia* oryzae Cav. on the Rice Plant

Piricularia oryzae Cav. appears in the rice fields of Hungary in certain years, when a considerably decreased yield often occurs. However, appearance of the fungus did not cause a decrease of yield in every case. It was noted that the crop in some cases was not affected at all with the plants infected by *Piricularia*, whereas in other cases there was total damage in absence of the fungus. As a result of several years of experiment it may be stated that the fungus which, in the opinion of some workers, is the cause of browning disease ('brusone') appears only on certain soil-types. Results obtained so far of the investigation of browning disease suggest that the presence of fungi is rather a consequence of the effects and conditions of unfavourable soil and weather on the plant than connected with the browning disease proper.

Research work on the cause of browning disease led to the view that injury resulted from hydrogen sulphide formed in the water-logged soil. Hydrogen sulphide inhibits respiration and uptake of water and nutrients by the plant[1]. Since the hydrogen sulphide is removed by oxygen, we considered the problem to be practically cleared up. At the same time both the disease and the fungus were absent in years when solar radiation was abundant and the photosynthetic processes were not impeded[2].

Further experiments were carried out to elucidate the relation between browning disease, the appearance of *Piricularia oryzae* and the intensity of photosynthesis. In our experiments we used the well-known Dunghan Shali variety, which is susceptible to browning disease. As it is well known that the amount of photosynthesis is different for light of different colours, plants in the same developmental stage were exposed to different colour effects. For this purpose four iron stands (130 cm. × 130 cm. × 200 cm.) were made and covered—except for the bottom—with black, white, red, and blue linen. These frames were placed under identical conditions over plants in various phases (tillering, stem elongating, blossoming) of development each for 6 days and the changes occurring in the covered plants were observed. Before the elongation of the stem, no fungal infection could be found in any of the plants.

Following elongation of the stem, the following observations were noted : Plants under a black cover died in every case. Those under a blue cover became thin and developed no further. Under red they elongated, while the leaves of the plants under white were covered with *Piricularia oryzae*. The leaves of the plants under a red cover showed no more fungal spots than those of control plants, where they were insignificant. After removal of the white cover the fungus-spotted plants produced under it continued development and gave crop.

As regards redox potential of the soil and oxygen content of the soil water, the most favourable conditions were under the red cover.

From these observations we conclude that the synthetic processes of the rice plant under the white cover are, to a certain extent, inhibited. In the leaves, as a result of disturbed physiological processes, free amino-acids, mainly glutamin and asparagin, accumulated and rendered possible the appearance of the fungus. On the other hand, under the red cover, the undisturbed vital process of the plants developing in the abundant red light prevents the fungus from becoming established. In these experiments, fungal infection could occur only after the elongation of the stem, that is, in the generative phase when the quantity of oxygen carried to the roots decreased significantly.

HÆMATOLOGY

Relationships between Blood Groups and the Fat Percentage of the Milk in Cattle

CATTLE show pronounced polymorphism with regard to blood groups. No less than eleven loci governing blood groups have been detected, and some of these carry very extensive numbers of multiple alleles.

Recent work[1–4] indicates the existence of relationships between some blood-group genes and characters of economic importance in cattle. Mitscherlich *et al.*[1,4] presented evidence for a negative influence of the M gene on total milk yield. I compared[2] the fat percentage of the milk, total fat yield and the heart-girth measurements of paternal half-sibs having and lacking certain blood-group genes belonging to eight different genetic systems. Statistically significant associations were found particularly between some blood genes and fat percentage; the latter trait having the highest heritability of the three production characters studied. Especially one of the multiple alleles at the B locus, namely, $B^{BO_1YD'}$, seemed to exercise a strongly positive influence on the fat percentage. Heifers carrying this allele had, on the average, a fat percentage which was 0·19 unit higher than that of their paternal half-sibs lacking this allele. Similarly the J gene had an increasing effect, while the L gene showed a negative influence on the fat percentage. A seemingly pleiotropic effect of some B alleles on the fat percentage was also reported by Neimann-Sørensen[3].

If a large number of tests are performed, statistically significant effects may be indicated even if no real biological association exists. The associations between the $B^{BO_1YD'}$, J and L blood-group genes and fat percentage found in my earlier paper have therefore been re-investigated on independent material.

Since 1955 the blood groups of all bulls used for artificial insemination in Sweden are tested. Records are now available of the daughters' fat percentage of several of these during the first lactation (305 days) and the deviation of each daughter-group from the contemporary herd averages with regard to fat percentage. These records (compiled by the bureau for progeny tests, N.A.T.) furnished material for the present study. Only those bulls were included the blood of which was tested before anything was known about the production of their progeny. For each of the blood groups studied, the bulls were divided into two classes, namely, those having and those lacking a particular blood group. For the Swedish Red and White breed (SRB) 205 bulls were studied, each having between 10 and 41 daughters (average 16·7), and in the Swedish Friesian (SLB), 77 bulls with 10–37 daughters each were analysed. The influence of the blood groups of the sires on the butter-fat test of their progeny is summarized in Table 1. For comparison the results obtained in previous work[2] on the effects of blood group genes within progeny groups are given in the right column of Table 1. The allele $B^{BO_1YD'}$ exercised a strongly positive influence on fat percentage in both the SRB and SLB breeds. Thus the fat percentage in daughter-groups from sires carrying $B^{BO_1YD'}$ exceeded that of the daughters from the remaining sires by approximately 0·10 unit. Most of the sires carrying $B^{BO_1YD'}$ were heterozygous. Slightly more than half their daughters may therefore be expected to have $B^{BO_1YD'}$. The total increasing effect of this allele on the fat percentage can therefore be estimated at about 0·20 unit. It may be recalled that in previous work carried out within progeny groups, the heifers having $B^{BO_1YD'}$ produced milk with 0·19 unit higher fat percentage than those lacking this allele.

In both the breeds the butter fat test of daughters from J-positive sires exceeded that of the offspring from sires lacking J with approximately 0·04 unit. The difference was not statistically significant within any of the breeds, but when the data on the deviation from the herd averages were pooled, a barely statistically significant effect of the J gene was obtained ($P \approx 0{\cdot}05$). However, no cumulative effect of the $B^{BO_1YD'}$ and J gene was found. In SRB the fat percentage of the daughters from the 15 sires carrying both these genes was thus almost exactly the same as in daughters from sires carrying $B^{BO_1YD'}$ only.

With regard to the L system finally, the results were conflicting. Within groups of paternal half-sibs of the SRB breed the L gene seemed to exercise

Table 1. INFLUENCE OF SOME BLOOD GROUP GENES CARRIED BY A.I. BULLS ON THE BUTTER-FAT TEST OF THEIR PROGENY*

Breed	Blood group genes	No. of sires	Fat percentage of daughters	t	Difference between progeny average and contemporary herd average	t	Weighted difference between paternal half-sibs having and lacking respectively genes (ref. 2)
SRB	With $B^{BO_1YD'}$	37	4·23	3·42‡	+ 0·11	3·66‡	+ 0·19‡

	With J	14	4·01	0·98	+ 0·04	0·87	—
	Without J	61	3·96		+ 0·01		
	With L	27	4·02	2·28*	+ 0·07	2·80†	—
	Without L	48	3·94		− 0·02		

* $P < 0{\cdot}05$. † $P < 0{\cdot}01$. ‡ $P < 0{\cdot}001$.

a negative influence on fat percentage. However, in the present work the daughters from the SRB sires of group *L* had almost exactly the same fat percentage as the daughters from sires lacking *L*. In SLB, on the contrary, the daughters from sires of group *L* had significantly higher fat percentage than those from sires lacking *L*.

Relationships between fat percentage and blood-group genes may be due to pleiotropy or linkage. If due to relatively close linkage, results such as those obtained in the present work with regard to *L* might be possible. The fact that in three independent materials comprising two different breeds the $B^{BO_1YD'}$ and *J* genes were associated with high butter-fat tests suggests that pleiotropic relationships exist between fat percentage and the corresponding two blood groups. In the case of the $B^{BO_1YD'}$ allele the increasing influence on fat percentage seems to be so strong that selection for this allele might possibly be used to raise the fat percentage of the milk. However, before such selection can be recommended in practice, its influence on other production traits must be known.

A full account of this work will be published elsewhere.

Hæmoglobins of Fœtal CBA Mice

IN man and many other species, fœtal hæmoglobin differs from the hæmoglobin of the adult, the difference being in the globin moiety and not in the prosthetic group[1]. The hæmoglobin in the blood of the new-born is often a mixture of fœtal and adult types. Adult *CBA* mouse blood can be shown, by starch gel electrophoresis, to contain at least 3 hæmoglobins (Cohen, B., personal communication). No one has, apparently, studied the fœtal hæmoglobins of *CBA* or other strains of mice.

In the present investigation, the blood of new-born and of fœtal mice was collected by decapitating the animals in heparinized saline. The red cells were washed twice in saline and finally packed by centrifuging at approximately 1,000*g* for 10 min. An equal volume of distilled water was added to lyse the cells and the cellular debris spun down. The supernatant provided the hæmoglobin samples to be investigated. Adult hæmoglobin solutions were prepared from the mother's blood in a similar manner.

The resistance of hæmoglobin to denaturation with 0·01 *N* sodium hydroxide has been investigated by Welling and van Bekkum[2], and our results on adult *CBA* hæmoglobin, observing the denaturation of diluted solutions in the spectrophotometer at 576 mμ, are comparable with their published figures. The hæmoglobins from new-born and fœtal mice were not sufficiently different from adult hæmoglobins in their resistance to the alkali to allow them to be readily distinguished; however, there appeared to be only two components in the curve for fœtal hæmoglobin while many of the samples of adult hæmoglobin showed an extra fast component. Similarly, no satisfactory differentiation could be made between these hæmoglobin solutions using the technique of oxidation to methæmoglobin with either 0·01 or 0·02 *M* sodium nitrite or with 0·0005 *M* potassium ferricyanide. The progress of the oxidation of dilute solutions of hæmoglobin was again followed at 576 mμ. Betke[3] has found that this technique could be used to characterize the human fœtal and adult hæmoglobins.

Starch-gel electrophoresis has been successful in identifying different hæmoglobin types of human[4] and mouse[5] blood. Accordingly, samples of hæmoglobins of fœtal, new-born and adult *CBA* mice were examined in this way. Particular care was taken with the early fœtal samples to ensure that no contamination of the fœtal blood with maternal or placental blood occurred. Washed and packed cell samples were lysed in their own volume of distilled water; *M*/1 phosphate buffer, *p*H 6·8, was added to double this volume and the solution centrifuged. The supernatant hæmoglobin solutions were converted to the stable cyanmethæmoglobin[6] form using potassium ferricyanide and potassium cyanide, and were then inserted into the starch gel on filter paper wicks. The Poulik discontinuous buffer system[7] was used with a current of 20–30 m.amp. at 6 V./cm. gel supplied by a low impedance, constant voltage, power pack. The current was passed for 6 hr.; the gel was then sliced and stained with a hydrogen peroxide/*o*-dianisidine solution[8]. Electrophoresis of the hæmoglobins was always carried out during the same day that the animals were killed. As can be seen from Fig. 1, the early fœtal hæmoglobins show a distinctive pattern. The samples of hæmoglobin from late fœtuses and new-born *CBA* mice were not, however, consistently different from those of the mothers. Further work on pregnancies, dated by

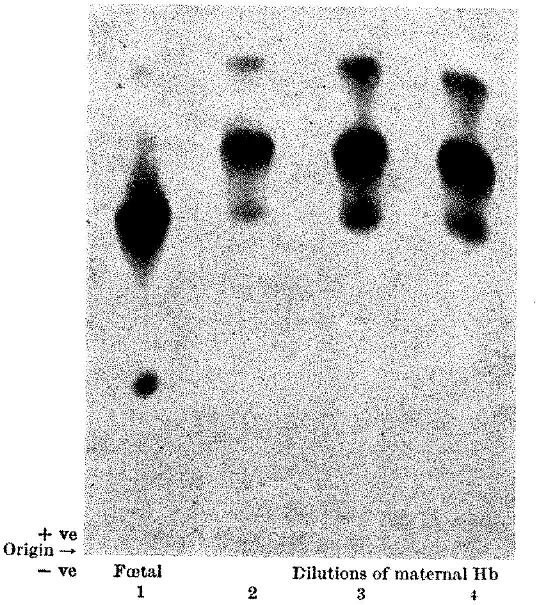

Fig. 1. Starch-gel electrophoresis (Poulik discontinuous buffer system, ref. 7) of cyanmethæmoglobins prepared from early fœtal and from three dilutions of maternal *CBA* mouse blood

vaginal plugs, showed that the early fœtal pattern was seen from the twelfth to the fourteenth or fifteenth day of inter-uterine life, but that from the sixteenth day onward the adult pattern was generally obtained. The early fœtal pattern differs from the adult in a diminution of the relative amounts of the fastest moving band and a predominance of the third rather than the second component. The slowest-moving band was well marked in the early fœtal samples but was also present, though irregularly, in later life: the significance of this slowest band needs to be investigated further.

It can thus be seen that, in *CBA* mice, early fœtal blood may be distinguished from later fœtal, new-born or adult blood by the relative distribution of the different hæmoglobins.

We wish to thank Mr. Bernard Cohen of the University of Glasgow for his help and advice during the course of this investigation.

PATHOLOGY

Brain Glycogen- and Copper-Levels in Normal Sheep and Sheep affected with Scrapie

Little is known about the biochemical changes responsible for the characteristic symptoms of scrapie. We intend to examine systematically the brain and other tissues for evidence of biochemical derangements. A communication describing the lack of alteration of the serum proteins has already been published[1].

Attempts to relate disease conditions in domestic animals to those in man can be most informative. While scrapie has been likened to kuru, a disease affecting tribesmen in a localized area of New Guinea[2], we have considered, in view of the familial nature of scrapie[3], that scrapie may be related to two familial conditions in man, one a glycogen storage disease (Castaigne-Lhermitte) and the other associated with an excess of copper in certain organs (Wilson's disease)[4].

In Casteigne-Lhermitte's disease, a familial cardio-muscular variant of Von Gierke's hepato-renal glycogen storage disease, histological examination of the nervous system reveals the accumulation of glycogen within the nerve cells, varying from small droplets to confluent masses. The latter may actually displace the nucleus. This raises the question as to whether these could be confused with the neuronal vacuoles characteristic of scrapie. In individuals with the glycogen storage disease there is a motor disability characterized by muscular hypotonia. Death usually follows from bulbar paralysis or respiratory infection. Somewhat similar nervous symptoms may occur in scrapie.

Wilson's disease is a familial disease characterized by progressive rigidity, a coarse tremor of the limbs and a spastic condition of the face, mouth and pharynx with some degree of dementia in the final stages. A few cases develop in the first decade, but the onset is most common in the second decade. The disease is associated with the finding of a great excess of copper in the liver, corpus striatum, and the cornea. This is due to the failure of the serum globulins to bind copper as it is absorbed from the intestine. While there are differences in symptomatology between this disease and scrapie, the importance of copper in sheep neuropathology[5] suggested the necessity for basic information on copper-levels in sheep affected by scrapie and normal sheep.

Six sheep in which symptoms of scrapie had been experimentally induced were killed, the brains frozen within 60 min. and kept frozen until analysed. Nine normal brains from a packing house and similarly treated were used as controls.

For glycogen, 1 gm. of the frozen brain was weighed into alcoholic potassium hydroxide and hydrolysed by Kerr's method[6]. The glycogen was separated by centrifugation, taken up in trichloroacetic acid solution and analysed by the anthrone procedure described by Kahan[7].

For copper, 15 gm. of sheep brain were ashed overnight in platinum at 600° C. The residue was repeatedly digested with nitric acid, dried and returned to the muffle at 600° C. for 1 hr. until white and then made up to volume with dilute hydrochloric acid. The final determination was carried out on a suitable aliquot by Forster's method[8].

Brain glycogen values of the six sheep affected by scrapie ranged from 0·86 to 1·04 mgm./gm. of dry matter while the range for nine normal brains was 0·57–1·18. The early onset of scrapie, differences in symptomatology and the fact that brain tissue from affected sheep does not show elevated glycogen-levels indicate that scrapie is not similar to Castaigne-Lhermitte's disease.

Brain copper values of affected sheep ranged from 12·2 to 16·7 parts per million of dry matter while the range for normal brains was 13·0–35·0. The values for scrapie sheep thus fall within the lower part of the normal range. This indicates that a defect in copper metabolism is unlikely to occur in the pathogenesis of scrapie and that there is little chance of a relationship to Wilson's disease.

Isolation of *Trypanosoma rhodesiense* from Wild *Glossina palpalis*

In an account of the epidemiology of human trypanosomiasis in south-east Uganda, Robertson and Baker[1] have referred to the momentous discovery by Bruce *et al.*[2] of the association between *Glossina palpalis fuscipes* Newstead and the devastating epidemic due to *Trypanosoma gambiense* in the early years of this century. Before the occurrence of *T. rhodesiense* Stephens and Fantham in epidemic form in 1940 [3] and its persistence afterwards, sleeping sickness in south-east Uganda was due apparently to *T. gambiense* and was considered to be transmitted only by *G. palpalis*.

During the epidemic of *T. rhodesiense* MacKichan[3] recorded the first isolation of this species from *G. pallidipes* Austen in the Lugala area of south-east Uganda and afterwards other isolations of *T. rhodesiense* from *G. pallidipes* have been made[4,5]. The interesting change from *T. gambiense* sleeping sickness to that due to *T. rhodesiense* and the similarity of the epidemiological picture of both forms of the disease in south-east Uganda have been commented on by Robertson and Baker[1].

Unsuccessful attempts to isolate *T. rhodesiense* from *G. palpalis fuscipes* have been recorded[3-5]. Rennison[4] failed to isolate any *T. brucei* group trypanosomes, and of Willett's five strains, the four which were tested proved non-infective to man.

During January and February 1960, 14,500 *G. palpalis fuscipes* were collected at Lugala (0° 12′ N.; 33° 54′ E.) in south-east Uganda, and allowed to feed, not merely to probe, in batches on guinea pigs and albino rats. From these animals 21 strains of the *T. brucei* group were isolated; no other species were detected. These strains were sub-inoculated into albino rats and samples of the blood of the latter animals, killed at high parasitæmia, were frozen and stored in a dry-ice cabinet.

Morphologically all the strains were of the *T. brucei* group and were readily established in albino rats. The mean prepatent period in rats, sub-inoculated with blood from the animals in which the strains were originally isolated, was 3·9 (range 2–12) days. The parasitæmias reached 50 or more trypanosomes per high-power field in a wet preparation (4 mm. objective, × 10 ocular) in a mean of 8·6 days. The mean longevity of these infected rats was 18·0 (range 8–48) days.

The strains were tested for sensitivity to tryparsamide (B.P.) by injecting mice, at high parasitæmia, intraperitoneally with tryparsamide, at the rate of 160 mgm./kgm. on the sixth day after inoculation; the parasitæmias were little affected and none of the animals was cured.

In order to discover whether any of the 21 virulent, tryparsamide-resistant *T. brucei* group strains were in fact *T. rhodesiense* the infectivity to man had to be ascertained. It was not possible to test each strain individually, so strains were pooled and inoculated into one man as described below.

The possibility of improvement of the condition of a patient with parenchymatous neurosyphilis by fever therapy was being considered. As *T. rhodesiense* produces an acute fever and the infection is curable in its early stage with suramin (B.P.), it was considered justifiable to combine a test of these strains with this therapy. The patient had a strongly positive Kahn test and showed serious mental deterioration. He did not come from a sleeping-sickness area.

Table 1. Batches in which 21 Strains of the *Trypanosoma brucei* Group were Inoculated into Man

Batch	Strain No.	Estimated No. of trypanosomes inoculated (millions)	Site of inoculation	Chancre
A	5	8·0	Left thigh	absent
	8	38·0		
	13	27·2		
B	1	0·6	Right thigh	present
	2	63·1		
	4	4·2		
	7	15·6		
	9	14·6		
	10	8·6		
C	11	16·8	Left arm	present
	12	5·5		
	14	10·5		
	15	30·6		
	16	23·1		
	17	4·7		
D	18	13·7	Right arm	present
	19	14·6		
	20	13·3		
	21	14·3		
	22	21·3		
	23	17·6		

The 21 animals, infected each with one individual strain from the frozen material, were grouped into four batches (Table 1). To a vial of 2·5 ml. sterile heparinized Ringer's solution was added 0·1 ml. of heart blood from each member of batch *A* (Table 1). After mixing, 2·0 ml. of this suspension were inoculated subcutaneously into the patient. This procedure was repeated for each batch *B*, *C* and *D*; the inoculations were made successively on day 0 at about 2-hr. intervals at the sites designated in Table 1.

The patient was examined each morning and thick blood films were examined daily. Trypanosomes were detected in the patient's peripheral blood on day 7 before a chancre had been seen. On day 8 characteristic chancres were seen at sites *B*, *C* and *D*. On day 9 the peripheral blood was estimated to contain 420,000 trypanosomes per cu. mm. A slight pyrexia (axillary temperature, 99·2° F.) occurred on the evening of the day 7 and was followed by a continued pyrexia (axillary temperature, 102·4°–104·0° F.) from day 8 to day 9, when the patient was treated with suramin. The temperature subsided by crisis on day 10. The patient's mental condition appeared a little improved.

To summarize these observations; all the strains isolated were highly virulent to rats or mice in the laboratory and were resistant to tryparsamide. In addition, at least one of the strains produced an acute infection with a high parasitæmia in man after a short incubation period. The appearance of chancres at three of the four sites of inoculation suggested that each of batches *B*, *C* and *D* contained at least one strain infective to man.

It is concluded that among the strains there was at least one strain of *T. rhodesiense*, possibly more.

This is the first isolation of *T. rhodesiense* from wild *G. palpalis*; furthermore, it is the first isolation of a trypanosome proving infective to man from wild *G. palpalis*. Taylor's[6] presumptive evidence that the salivary infection in a *G. palpalis* at Ganawuri was *T. gambiense* is discussed by Buxton[7]. The widely held view that *G. palpalis* is only associated with *T. gambiense* sleeping sickness must clearly be re-examined.

We wish to express our appreciation of the encouragement given by Dr. W. H. R. Lumsden, director of the Organization, to epidemiological studies which have led to this result. Acknowledgment is given to Dr. P. E. C. Manson-Bahr and Mr. A. E. C. Harvey for their co-operation and help.

RADIOBIOLOGY

Quantitative Cytochemistry using Directly Applied Radioactive Reagents

While radioactive isotopes have found valuable application in many cytochemical studies of metabolic incorporation processes, little use has so far been made of such labels in cytochemical reactions applied directly to the localization of substances in tissue specimens. Some qualitative applications to enzymic cytochemistry, for example, using metals or phosphorus-32 in deposited products, have been reported[1]. We have now examined the applicability of tritium-labelled reagents which form covalent bonds at specific sites in tissue components, as a method in quantitative cytochemistry. The advantages of such a method will include, *inter alia* (cf. ref. 2): (1) an escape from some of the problems of selectively introducing sufficient light-absorption at specific sites, since the label can be carried on many suitable simple reagent molecules; (2) autoradiographic measurement, which is free of certain of the problems of micro-spectrophotometry and is independent of the molecular environment of the target sites; (3) checks and calibrations of micro-spectrophotometric methods for the same components, and the possibility, at least in principle, of absolute determinations.

To establish the basis of the method, the acylating reagent acetic anhydride, labelled with tritium, was applied (0·4 *M*) in pyridine-acetonitrile as a general blocking agent[3], to indicate the total number of groups available to acylation, notably $—NH_2$, $—OH$ and $—SH$ groups in macro-molecules. Frog red cells (in plasma-free smears) were exposed to a layer of reagent solution in small, closed tubes. Thorough subsequent washings, in turn in unlabelled reagent, sodium acetate solution and water, removed all excess isotope. Satisfactory and reproducible autoradiographs were obtained, by the stripping film method of Pelc[4], after short film exposures (for example, 2 days, for reagent at 1·5 $\mu c./\mu M$). The amount of isotope bound per cell increased with the reaction period, up to a maximum value (Fig. 1). Nil counts above background were found in cells similarly treated but having a prior treatment (15 hr.) with unlabelled reagent.

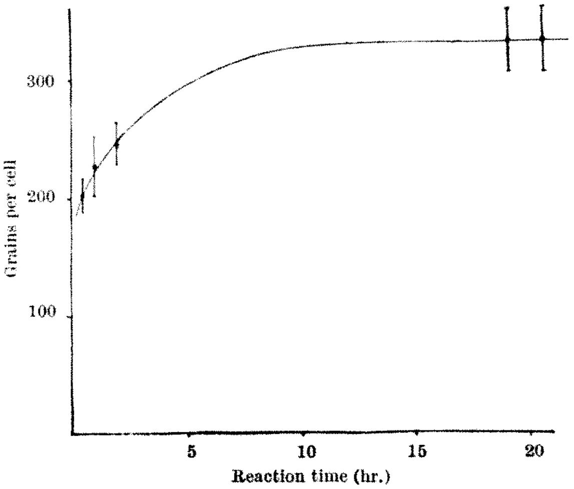

Fig. 1. Mean grain count (± *S.D.*) per cell, in normal frog red cells, after different periods of reaction

The total number of groups (N) available to this reagent in the normal frog red cell (lengths of axes in the ranges 20–23μ and 13–15μ) was found to be $5 \cdot 8 \times 10^{-13}$ mole (or $3 \cdot 5 \times 10^{11}$ groups). This is consistent with reaction at a large majority of the potential acceptor sites in the macromolecules in this cell. Such a figure is calculated from the equation:

$$N \text{ (moles per cell)} = \frac{2\, n_{\max.}}{g_1.g_2.a.t.s.},$$

where $n_{\max.}$ is the maximum number of grains that can be developed per cell after treatment with reagent at specific activity s (disintegrations per min. per mole) and film exposure of t min.

g_1 and g_2 are grain-yield correction factors. g_1 is equal to the mean number of grains actually developed per activating β-particle. Multiple grain activations are betrayed by close clusters of 2 or 3 grains, and an idea of the magnitude of g_1 is obtained by scoring these as units. Such re-counting gave $g_1 = 1 \cdot 28$ (*S.E.* 0·03) which, in view of the inclusion of accidental clusters, is the upper limit. g_2 corrects for all those incident β-particles not producing grains, due to latent image fading, low energies, multiple collisions, etc. In practice, only $g_1.g_2$ is required, and this product was determined empirically by comparison of the emergent β-particle flux from a specimen (read in a gas-flow counter) with the number of grains developed in an autoradiograph of the same specimen. This ratio gave a value of 0·85 for $g_1.g_2$.

Self-absorption is represented by the absorption correction factor a. Assuming the absorption data of Fitzgerald *et al.*[5] hold here, and if the equivalent mass per unit area of the cell is known (found here by interferometry[6]), the total absorption can be obtained by an appropriate integration. This method gives $a = 0 \cdot 21$ here (that is, 21 per cent transmission). A direct determination of a was also possible, by measurement of the emergent β-particle flux from a specimen, followed by extraction and measurement (in a gas-flow counter) of the total radioactivity of that specimen. Two such experiments gave values of 0·18 and 0·19 for a. The directly determined value was preferred in calculations of N.

For comparative work, the correction factors evaluated here can be ignored, but for absolute determinations they must be investigated for each new type of material. The routine use of standard labelled specimens, for example of acylated frog red cells as here, is useful as a means of monitoring variations in the autoradiography of other treated specimens.

Similar methods can clearly be applied with other reagents for the determination of important types of groups in various cells. We have found that the number of available protein $-NH_2$ groups can apparently be measured by use of the same reagent in cold, aqueous buffer (cf. ref. 7). With the use of unlabelled, selective blocking agents, or with the introduction of labelled acetyl into other reagents, or with the use of reagents of other types labelled with tritium (or carbon-14 or sulphur-35 where the highest resolving power is not required), the measurement of other cell components will be feasible.

A fuller account and discussion of these and related experiments will appear elsewhere. We thank Dr. S. R. Pelc for discussion, and the Medical Research Council for a grant to support this work.

Modification of Radiation Damage in Seeds by Post Treatment

IN their recent paper on modification of radiation damage in dormant seeds by storage, Curtis *et al.*[1] reported that very dry barley seeds if germinated immediately after irradiation show the same damage as seeds of higher water content. The very dry seeds, however, as distinct from those of higher water content, showed a considerable storage effect, the damage increasing as the seeds are stored between irradiation and soaking. In these experiments soaking was carried out under anaerobic conditions for an initial period of 1 hr.

The existence or absence of a storage effect in irradiated seeds has been reported by many workers[2]. However, the moisture content of the seeds, which greatly influences their radiation sensitivity[3], was not controlled in most of these earlier investigations. In the remaining papers there appears to be no agreement on how the observed storage effect is related to the water content or how it is influenced by the conditions of storage and soaking. In order to shed some light on these questions, a study of the storage effect in *Vicia faba* seeds was therefore undertaken using precisely controlled experimental conditions.

The material used was *Vicia faba* var. *minor* 'Throws M.S. Winter Beans', kindly supplied from Hasler and Co., Ltd., Dunmow, Essex. The beans were stored in desiccators in single layers over sodium hydrogen sulphate or calcium chloride, the water content being measured by crushing samples of 20 and drying at 105° C. to constant weight.

Seeds of different water content were pricked and given 3,000 r. or 10,000 r. X-rays, using 200 kV., 15 m.amp., 2 mm. aluminium, 550 r./min. Irradiated seeds and controls were either soaked 4 min. after the end of irradiation for an initial 8-hr. period, or stored for 8 weeks in desiccators and then soaked. Water content was kept constant during storage. It can be shown that, after 8 hr. soaking, 90 per cent of embryos are fully soaked, whole seeds having taken up about 85 per cent of their original dry weight of water. The soaking was done in quartz-distilled water at 20 ± 1/4° C. Either air free of carbon dioxide, or nitrogen free of carbon dioxide and oxygen (purified product of Linde A.G. with oxygen content of less than 0·001 per cent, purified further by passing over catalytic copper[1]) was bubbled through the water during soaking.

Seeds were then grown in pots of moist sawdust in an incubator running at 20 ± 1/4° C. and 90–95 per cent relative air humidity. Germination was determined and root and shoot length measured 11 days after soaking. The beans were stored in darkness except for the final pricking and irradiation, and soaked and grown in darkness except for 10 min. daily at less than 20 ft.-candles. These short exposures to light should not affect the ultimate length of the shoot[5,6]. For each experimental procedure three pots of 20 beans were used. The significance of the resulting differences was tested by means of analysis of variance.

For seeds of 9·7 and 10·4 per cent water content the different conditions of soaking after irradiation had no effect on the percentage germination using either of two criteria: (*a*) visible splitting of the testa over the tip of the radicle; (*b*) root- or shoot-length longer than 0·5 cm.

Root and shoot growth results for the same experiments are summed up in Fig. 1. The root and shoot growth is expressed as a percentage of the individual controls in Table 1.

Table 1. Length of root and shoot after 11 days growth expressed as a percentage of individual controls for beans of 9·7 per cent moisture content, irradiated with either 10,000 r. or 3,000 r. and soaked immediately or after 8 weeks storage, in either nitrogenated or aerated water

Soaking time	Soaking procedure	3,000 r.		10,000 r.	
		Root	Shoot	Root	Shoot
4 min. after end of irradiation	Nitrogen	63·9	45·3	21·5	7·6
	Air	66·2	43·9	22·1	8·3
8 weeks after end of irradiation	Nitrogen	58·0	38·3	26·1	10·3
	Air	64·8	41·2	23·5	8·4

It can be seen that there was a strong effect of both irradiations on root- and shoot-length, but no clear effect of the other factors in question. Statistical analysis shows that apart from the irradiation ($P \ll 0·001$) only moisture content gave significant differences in root and shoot length ($P = 0·01$–$0·001$). Seeds with 9·7 per cent humidity at zero soaking time gave slightly shorter roots and shoots than seeds with 10·4 per cent humidity. This damaging effect of drying in *Vicia faba* var. *minor* seeds was pointed out earlier[7–9]. According to the new results it appears to be significant for very small differences in water content. It should be mentioned, however, that growth reduction in the hybrid stock used here at 9·7 per cent water content was small, com-

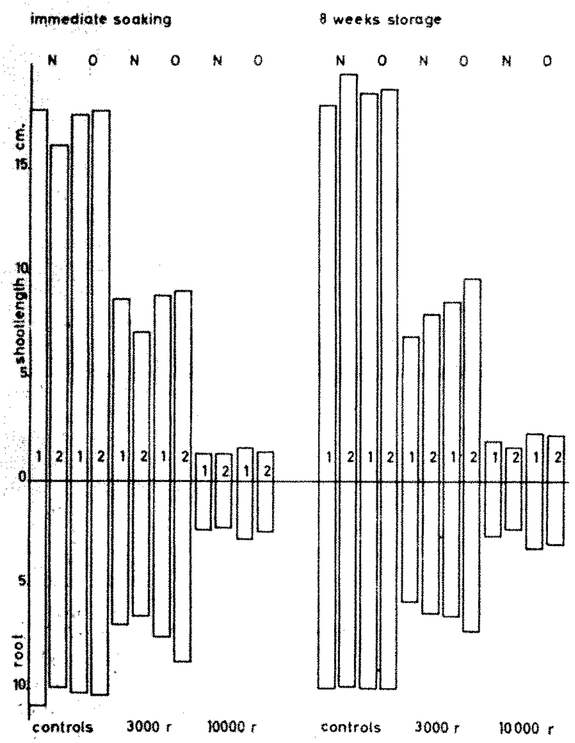

Fig. 1. Shoot- and root-length of seedlings eleven days after soaking. Seeds of two moisture contents, 9·7 per cent (1) and 10·4 per cent (2). Doses of 3,000 r. and 10,000 r. X-rays. Soaking, 4 min. or 8 weeks after end of irradiation, under aerobic (*O*) or anaerobic (*N*) conditions. Means from 60 beans in each case

pared with the earlier findings for an inbred line and that seeds of 15·1 per cent water content gave no better growth than those of 10·4 per cent.

Apart from these two effects there was no other significant effect. Neither the period of storage, nor aerobic or anaerobic soaking had any effect on the radiation damage observed, nor was any higher interaction observed between radiation and storage, or radiation, storage and soaking procedure. It should be mentioned that *Vicia* seeds of higher moisture content (12 per cent) when irradiated with 3,000 r. gave no growth reduction (experiments carried out in Southampton, unpublished), which shows that the water content used here (9·7 per cent, giving about 42 per cent growth reduction in shoots for 3,000 r.) was of the right order for *Vicia* seeds for testing the effects in question.

The above results, though at variance with those of Curtis *et al.*[1] and other workers on barley in showing no post-radiation effect of storage or of availability of oxygen during soaking, do not preclude the possibility that these effects may occur in *Vicia* under different conditions. Curtis *et al.* used barley seeds dried to very low water content; they gave higher doses and grew their seedlings in the light. However, it seems important to point out that any generalization concerning 'storage effect' and 'modification by post-treatment' is at present premature, and it is clear that further experiments of a wider scope and with other materials are necessary in order to determine the conditions under which such effects appear.

I am indebted to the Department of Scientific and Industrial Research and the Deutsche Akademische Austauschdient for a research fellowship in Great Britain, during which earlier stages of the work reported here were carried out. Sincere thanks are due to Dr. G. R. Lane of the Botany Department, University of Southampton, for valuable suggestions and constant encouragement during the period of study there, as well as for very carefully going into part of the experimental data and for help in the English manuscript. I am also indebted to Dr. L. H. Gray, Northwood, Middlesex, and to Dr. H. J. Seifert of the Chemistry Department, Giessen, for kind suggestions regarding the gases used. Irradiations were done at Southampton by Dr. J. R. Clarkson of the Royal South Hants and Southampton Hospital, at Giessen by Prof. Th. Hornykiewitsch and Dr. W. Hartung of the Medizinische Klinik der Universität. Their kind co-operation is gratefully acknowledged. The work in Giessen is supported by the Deutsche Forschungsgemeinschaft. A more detailed account will be given elsewhere.

BIOLOGY

Rapid Preparation of Fresh Frozen Sections of Barley Roots

In the course of investigations of the movement of nutrient ions through barley roots, it became necessary to stop the movement instantaneously and study the distribution of the nutrient ions at that time. A technique was devised that involved stopping the reaction at liquid-nitrogen temperature and sectioning the frozen tissue for subsequent radioautography. The purpose of this communication is to report on a method of preparation of fresh frozen sections involving no prior fixation of the tissue.

The barley roots are placed in water at 0–5° C. for 1 min. They are then oriented in a slightly congealed 5 per cent gelatin mixture containing 3·5 per cent glycerine jelly. The matrix is prepared by mixing 50 c.c. of melted 10 per cent gelatin mounting medium containing 0·5 per cent carbolic acid ('Harelco'), 7 c.c. of glycerine jelly mounting medium (Brandt), and 50 c.c. of water. The mixture is allowed to cool to a soft jelly and spooned into a small embedding box that has been chilled in 'dry ice'. The roots are immediately pushed into the 'jelly', oriented and the whole embedding box placed in *iso*pentane that has been cooled by liquid nitrogen to approximately −160° C. If the drop in temperature is too rapid, the matrix blocks will often crack, and at least a minute should be allowed to bring the blocks to −160° C.

After freezing, the blocks are left at room temperature for a few minutes to allow them to be cut from the embedding boxes and then placed in a cryostat kept at approximately −22° C. When tissue blocks are brought up to this temperature, recrystallization begins to occur, although rather slowly[1]. Nevertheless, within two days the cutting characteristics of the tissue blocks change noticeably. Very low-temperature storage is advisable if blocks are not cut within a day or two. The blocks are mounted and cut at −20° to −22° C. The Minot microtone, lubricated with 'Arctic' oil, has been satisfactory, and 16-μ sections of barley roots can be cut as a matter of routine. The use of a glass window[2,3] on the knife prevents cutting the section.

Figs. 1 and 2 show cross-sections and transverse sections of water-mounts cut according to the above procedure. The photographs were taken within fifteen minutes of the tissue being cut. There is no indication of physical alteration of the tissue during preparation or cutting. The cross-section and transverse sections are similar to the illustrations of Heimsch[4] of barley roots prepared by standard techniques involving paraffin impregnation.

After sectioning, alternate procedures are possible depending on the use to be made of the section. The section may be brushed on to a warm gelatinized slide, where melting and flattening take place at once. The sections dry very rapidly, and solutions such as water or vital dyes should be added immediately. A procedure found successful for morphological detail is to brush the section on to a warm gelatinized slide flooded with 10 per cent neutral formalin and allow it to dry at room temperature. Sections may then be stained and mounted by standard procedures. For radioautography sections may be brushed directly on to photographic plates.

One of the advantages of the present procedure is its rapidity. A sample of fresh plant tissue can be excised, frozen, cut and a section obtained on a microscope slide within an hour, depending primarily on the length of time necessary to raise the blocks from −160° to −22° C.

Another advantage is that a chemical, and to some extent physical, reaction can be stopped or slowed at any given time and the tissue examined within the hour. In our own case, we are interested in ion movement in tissue. We can stop this reaction, and by the use of radioautographs localize the presence of the ions. Other applications in chemical studies, enzyme analyses, and micro incineration are as applicable to plant tissues as to animal tissue prepared by similar techniques[5].

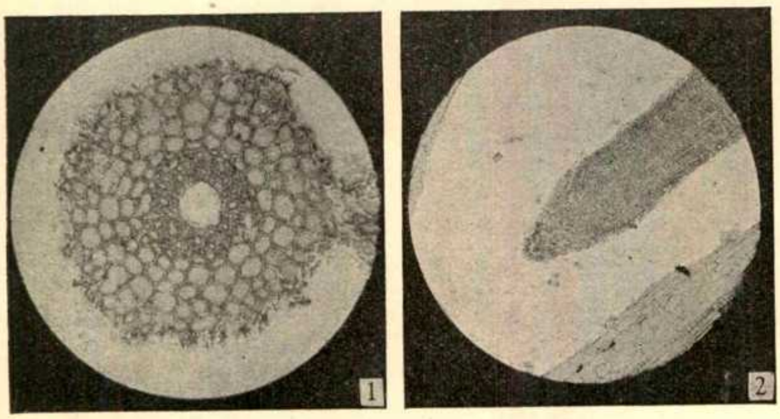

Fig. 1. Water mounts of 16-μ sections of six-day-old barley roots obtained by cutting at −22° C. a frozen gelatin block containing the roots: (1) cross-section, approximately × 400; (2) transverse sections, approximately × 150. Root tip in centre

The present method prepares fresh frozen plant-sections involving no prior fixation or dehydration of the tissue, in contrast to other frozen tissue techniques requiring drying[6] or prior fixation. Thus, artefacts and changes occurring during tissue preparation are minimized to vanishing point.

Although the method has been used only on roots of young barley plants, it shows promise as a general method for the rapid preparation of fresh tissue sections without prior fixation.

Low-Temperature Injury in Lovegrass (*Eragrostis curvula* (Schrad) Nees)

Eragrostis curvula is a perennial bunch grass widely used in South Africa. In order to determine the low-temperature tolerance of this grass, the following experiment was carried out. Twenty dormant stools of *E. curvula* ('Ermelo' variety), cut to within 3 in. of the ground, were transplanted in the winter (May 28) of 1958 into 4-gal. tins, and watered. Ten of these tins were placed in an illuminated constant-temperature room at 31° C. (87·8° F.) on July 9. Active growth started within a day, and the plants reached a height of more than 12 in. within nineteen days. On July 28 the plants were grouped in pairs, each of which was subjected to one of the following temperatures for three days: − 16·7° C. (2° F.), − 13·3° C. (8° F.), − 12·2° C. (10° F.), − 10·8° C. (12·5° F.) and 1·7° C. (35° F.). They were then transferred to a glasshouse (at approximately 24° C. (75° F.)) for further observation. All stools had been killed by low temperature.

Of the remaining ten tins, two were placed in each of the illuminated low-temperature rooms maintained at temperatures of −16·7° C. (2° F.), −13·3° C. (8° F.), −12·2° C. (10° F.), −10·8° C. (12·5° F.) and 1·7° C. (35° F.) on July 9. On July 28 these tins were transferred to high-constant-temperature rooms (31° C. (87·8° F.)) for three days, after which they were placed in a glasshouse (approximately 24° C. (75° F.)) for further observation. Only the two plants which had previously been maintained at 1·7° C. (35° F.) resumed growth within two days, the remainder having been killed.

These observations support the views of Crider[1], who suggested that most perennial crop plants were subject to greater winter injury if previously encouraged by irrigation or other means to remain in a succulent condition until cold weather set in, and further that winter injury could not be attributed to low temperature alone.

Effect of Polyhydric Alcohols on Frost Hardiness in Plants

In previous communications[1-3], I have reported that the increase of sugar content in a plant cell increases its frost hardiness, and that polyhydric alcohols, especially ethylene glycol and glycerol, also show the same protective action as glucose and sucrose against freezing injury in *Gardenia* leaf cells.

Recently, some attempts[4,5] have been made to determine the correlation between the seasonal fluctuations of glycerol content and frost hardiness in some insects. However, no evidence has yet been obtained to show whether the increase in polyhydric alcohols, especially in glycerol, is an important cause of frost hardening in plants or not. Therefore, the fluctuations of various polyhydric alcohols in the bark of twigs or leaves of 19 different species of woody plants were studied chromatographically in the course of both natural and artificial frost hardening. An aliquot of the extract of high concentration of polyhydric alcohols, prepared by the usual method, was developed on a filter paper, using a solvent containing *n*-butanol–water–acetic acid (4 : 1 : 2). In order to separate mannitol and sorbitol, the process was repeated five times. Quantitative analysis of three polyhydric alcohols was carried out, based on oxidation with periodate of the polyhydric alcohols eluted from the filter paper and subsequent colour reaction with a chromotropic reagent.

In winter, the glycerol content in tea, climbing spindle tree and *Platanus* ranged from 0·1 to 0·15 per cent (wet weight), while in the other 16 species its content was very small (Table 1). Furthermore, glycerol content showed only a slight change which was obviously not significant, in both seasonal and artificial hardening. Therefore, it may be safely said that glycerol does not play an important part in the frost hardening of woody plants.

In winter, the content of mannitol ranged from about 0·1 to 0·5 per cent (wet weight) in many species (Table 1). Sorbitol content amounted to about 1 per cent in the apple tree (twig bark), *Gardenia* (leaf), pomegranate (twig bark) and mountain ash (twig bark), but its content is very small in the other 15 species (Table 1). In winter the contents of mannitol and sorbitol in many species increased 2–3 times as much as in August; but in the mulberry tree they were reduced to a half the summer value. From summer to winter, the increase of total polyhydric alcohols in bark of twig of apple tree was about 38 per cent of that of total sugars during that period, but the values of all other 6 species used were less than about 7 per cent.

The total content of polyhydric alcohols in the pomegranate (bark), *Gardenia* (leaf), apple tree (bark) and mountain ash (bark) in winter ranged from about 40 to 55 per cent of the total sugar content, but in the other 15 species it does not amount to more than 12 per cent (Table 1).

In artificial hardening in early October, when such hardening is remarkably effective, the increase in polyhydric alcohols did not exceed about 0·1 per cent (wet weight) in many species; at the same time, increase in sugars ranged from about 1·0 to 1·6 per cent (wet weight) in all species. Moreover, any positive correlation between the amount of polyhydric alcohols and the hardiness of trees was not observed in 17 species examined (Table 1).

From the results mentioned above, it is obvious that in both natural and artificial frost hardening polyhydric alcohols play little part in the increase of the frost hardiness in most woody plants. However, in the species in which the total content of polyhydric alcohols amounts to about 40 per cent of the total sugar content, namely, in the *Gardenia*, apple tree, mountain ash and pomegranate, polyhydric alcohols

Quantity of polyhydric alcohols and sugars are expressed in percentage fresh weight. Degree of frost hardiness is represented by the minimum temperature at which the twig or leaves are able to survive freezing for 24 hr. *(At least.) All samples were taken in January exclusive of *Sorbus commixta* and *Picea glehnii*, which were taken on March 1.

are considered to play some part in the increase of their frost hardiness.

Growth of Lake Victoria Phytoplankton in Enriched Cultures

It has been stated that many of the natural waters of Africa are short of sulphates[1], and as a broad generalization this is not to be denied. However, it has also been suggested that sulphates, as well as nitrates and phosphates, are a limiting factor for plankton growth in Lake Victoria[2], and that shortage of sulphates in solution is a factor affecting the productivity of the Lake[3]. During a recent six-months stay at the East African Fisheries Research Organization Laboratory in Jinja, Uganda, a small part of my time was devoted to culture experiments, and some successful attempts were made to grow Lake Victoria phytoplankton in laboratory culture.

The phytoplankton most usually dominant in Lake Victoria is *Melosira nyassensis* var. *victoriae*, though other diatoms, including *M. granulata*, *M. italica*, *M. agassizii* and *Nitzschia acicularis*, and blue-green algae, including *Aphanocapsa elachista*, *Merismopaedia elegans* and *Lyngbya circumcreta*, are often present. *Melosira* is the most important genus and forms the major source of food, in the Lake itself, for the herbivorous fish, *Tilapia esculenta* and *T. variabilis*, and most attention was paid to *Melosira* in this investigation.

To each of thirteen clean, sterilized, plugged 250-ml. conical flasks was added a 125-ml. aliquot from a fresh, well-mixed, water sample from the Lake. One of these was treated as a control, and to each of the others was added sterile nutrient solution as follows: to cultures S_1, S_2 and S_3, 10 ml. of magnesium sulphate solutions of such concentrations as to produce culture concentrations of, respectively, 1·3, 13 and 130 mgm./l. of sulphate; to cultures P_1, P_2 and P_3, 10 ml. of dipotassium hydrogen phosphate solutions to produce, respectively, 0·874, 8·74 and 87·4 mgm./l. of phosphate; to cultures N_1, N_2 and N_3, 10 ml. of potassium nitrate solutions to produce, respectively, 1·07, 10·7 and 107 mgm./l. of nitrate. To each of a fourth series of three cultures, SPN_1, SPN_2 and SPN_3, was added a mixture of the three nutrient substances at the concentration-levels as described. In calculating these concentrations it was assumed that sulphate, nitrate and phosphate were nil in the Lake water.

Counts of algae were made, by the sedimentation method[4-6] in the original Lake sample, and for each of the thirteen cultures at intervals of six or seven days for the next three weeks. A final count was made for some of the cultures after a further four weeks.

The response of *Melosira* (mainly *M. nyassensis* var. *victoriae*) to some of these different cultures is shown in Fig. 1. No growth occurred in S_1 and S_2, and the difference between S_3 and the initial inoculation density is insignificant. It can be stated, therefore, that added sulphate had no effect on the growth of *Melosira*. Nitrate at 1·07 and 107 mgm./l. had no effect on the growth of *Melosira*, and the cultures N_1 and N_3 are not recorded in Fig. 1. Nitrate at 10·7 mgm./l. (culture N_2) apparently boosted growth initially but after a further six days many dead cells were found in the N_2 culture. On the other hand, the addition of phosphate, particularly in the most dilute form, resulted in a significant increase in *Melosira*. After a further four weeks there were more than 3,000 cells per ml. in culture P_1. *Melosira* also showed a significant increase in culture SPN_3, where all three nutrients were added at the most concentrated level. No growth occurred in SPN_1 or SPN_2; but the reason for this is unknown.

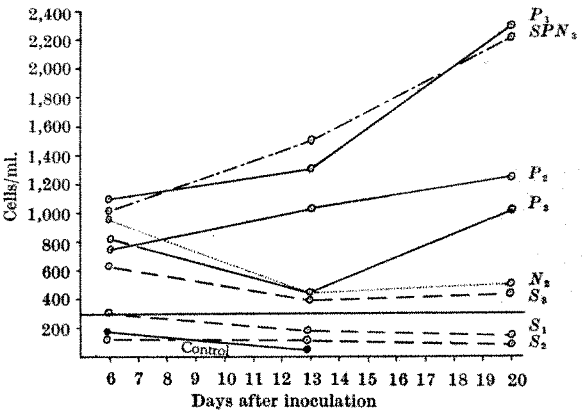

Fig. 1. Effects of added nutrients on growth of *Melosira* spp. in mixed cultures. Horizontal line, original inoculation density

None of the three species of blue-green algae investigated showed a significant increase on the addition of phosphate, nitrate or sulphate; but factors other than nutrient limitations might have been responsible for this.

The Chlorococcales present in the original inoculum, especially *Ankistrodesmus falcatus*, showed an increase in all the cultures with additional nutrients, least so for phosphate and most for nitrate at 107 mgm./l. For these forms, then, the level of sulphate concentration in Lake Victoria might be, with nitrate and phosphate, a limiting factor, and this agrees with the results of culture experiments in which test algae were used[2].

The most important genus, *Melosira*, in the Lake Victoria phytoplankton, however, is apparently not limited by the level of sulphate but is sensitive to phosphate, and hence the biological productivity of Lake Victoria, at the present time, is probably more dependent on phosphate than on sulphate.

I should like to express my gratitude to the Colonial Office for the award of a six-months research fellowship during the tenure of which this work was carried out.

A Simple Medium for the Demonstration of Chlamydospores of *Candida albicans*

WHILE investigating the formation of chlamydospores by different species of the fungus *Candida*, it was observed that human serum as a medium gave good results. Cultures of *Candida albicans* 10, *Candida tropicales* 10, *Candida krussei* 10, and *Candida stellatoidea* 10, *Candida guillarmondi* 1, and *Candida pseudotropicales* 1, were examined by the following technique: 24-hr. growth in Sabouraud's dextrose agar medium was emulsified with 1 c.c. of sterile normal saline; then 1 c.c. of this emulsion was added to a test-tube containing 4 drops of normal human serum, and the tube was incubated at 37° C. in a water-bath. After a lapse of 24, 48 and 72 hr., cover-slip preparations were examined under the microscope. In each instance, where cultural and biochemical tests for a strain conformed to those for *Candida albicans*, chlamydospores were produced after a lapse of 24 hr. Chlamydospores, however, did not develop with other types. Thus the above findings show that this method is very simple, less expensive and less time-consuming than routine methods.

Growth of a Nematode in Tomato Plants grown on Sodium-deficient Water Cultures

HOST plants deficient in nitrogen, phosphorus, potassium, magnesium, sulphur and iron will support a population of the root-knot nematode *Meloidogyne javanica*[1], whereas plants on full nutrient and heavily infected with *M. incognita acrita* do not show deficiencies of these elements[2]. It has been reported[3], however, that tomatoes infected with *M. incognita acrita* show less sodium in their tissues than do uninfected plants.

It may be that members of the genus *Meloidogyne* require large amounts of sodium during their development, and the following experiment was undertaken to test the effect of 'sodium deficiency' on the growth and reproduction of *M. javanica* grown in tomatoes. The terms 'sodium deficient' and 'sodium free' used here refer to plants grown in water cultures in which the presence of sodium has been reduced to a minimum.

All seeds used came from a single susceptible tomato plant of the variety Pan America. They were washed six times in water distilled from a silica still which was changed hourly. This water, which was used throughout the experiment, contained 0·0002 p.p.m. sodium.

Nutrient salts were re-crystallized as many as six times, and their sodium content estimated before use. The seeds were germinated on nylon mesh over distilled water. When the radicles were about 1 cm. in length, a culture solution of half concentration containing 0·0042 p.p.m. sodium was substituted for the distilled water. The concentrations of salts used and the methods of growth in polythene containers have been described[4].

Sodium was estimated, using a 'Si-Ro-Spec' atomic absorption instrument[5], on a dry-weight basis. The methods used in infecting the plants and in measuring the growth of the nematodes have been described[1], except that the agar was dialysed against distilled water as a 5 per cent gel for five days with six changes before it was used. A 0·5 per cent solution of the dialysed agar was used as the infecting medium.

Infective larvæ of *M. javanica* were washed several times over a sintered glass filter of pore diameter 5–15μ before being placed in the agar. The plants were exposed to infection for a period of 48 hr. and were then removed. The roots were washed in distilled water before being returned to the nutrients.

The plants were grown in a cooled glass-house from which dust contamination was reduced by a positive pressure of filtered air. A diurnal temperature variation between 60° and 110° F. was maintained during the experiment.

Plants grown in the presence of sodium were grown in culture solutions identical with those without sodium except that they had 0·1 m.equiv./litre of sodium sulphate added. The roots and leaves of these plants were hydrolysed separately in silica Kjeldahl tubes using a mixture consisting of 5 ml. concentrated nitric acid, 1 ml. concentrated sulphuric acid and 1 ml. concentrated perchloric acid, all these chemicals being A.R. grade. Blanks consisting of these chemicals were included in all hydrolyses and sodium estimations.

Throughout the experiment the growth of plants in all treatments was similar. Plants were harvested at 7, 14, 21 and 28 days, and their dry weights were similar, whether or not they were infected or whether or not they had sodium. At the final harvest, average weights of twelve plants from each of the two treatments were approximately the same (6·4 gm.).

The amounts of sodium in the roots and leaves of these plants showed marked differences. Tomato plants grown on a 'sodium free' culture solution showed uniform amounts of sodium which ranged from 20 to 50 p.p.m. throughout the entire experiment for both roots and leaves; the roots always contained sodium in a slightly higher concentration than the leaves.

Plants grown with sodium showed a steady increase in uptake of this element in the roots throughout the entire experiment, ranging from 120 p.p.m. at the first (seventh day) harvest to 1,410 p.p.m. at the final (twenty-eighth day) harvest. The leaves of these plants, however, did not show an increase in sodium concentration throughout the experiment.

These results suggest that sodium accumulates in the roots of tomato plants when the amounts mentioned above of sodium are supplied. Infection was not consistent using agar, and although great care was taken to make this procedure as uniform as possible, in several instances plants remained uninfected.

Infected 'sodium-free' plants were harvested at 7, 14 and 28 days, and galled roots were cut away from the plant and fixed in buffered 1 per cent osmium tetroxide at *p*H 7·2. They were washed in several changes of distilled water and at each harvest fifty nematodes were dissected at random and their cross-sectional area measured as previously described[1].

Growth of these nematodes on tomatoes containing 20–50 p.p.m. sodium was quite normal. They moulted, produced egg sacs, eggs and viable larvæ which were capable of re-infecting tomato seedlings, and it appears that the amount of sodium removed from 'sodium-deficient' tomato plants by light infections (several hundred per plant) of these parasites is negligible, as at the final harvest infected 'sodium-free' plants gave a reading of 40 p.p.m. sodium compared with 35 p.p.m. sodium for uninfected 'sodium-free' plants. From these observations it is clear that *Meloidogyne javanica* does not require a large amount of sodium during its development.

Mechanism of Trail-laying in Two Species of Termites

DURING recent investigations on the behaviour of the primitive termite *Zootermopsis nevadensis* (Hagen), evidence for trail-laying was obtained when it was noted that nymphs accurately followed the path taken by one nymph over a clear unobstructed surface in an artificial nest, even when the direction of the light and the position of the nest were altered. This, to my knowledge, is the first mention of trail-laying in a lower termite.

Subsequent experiments using squashes and petroleum ether extracts of various parts of the body and organs of individuals of *Z. nevadensis* and *Nasutitermes cornigera* Motschulsky have shown that in these two genera, belonging to two widely separated families (Hodotermitidae and Termitidae), trails are produced by a substance secreted by a gland in the ventral part of the fifth segment of the abdomen. Grassé and Noirot[1], however, from work on *Macrotermes bellicosus* (Smeathman), *Macrotermes natalensis* (Haviland) and *Odontotermes magdalenae* (Grassé and Noirot) believe that in these species trails are marked by fæcal droppings or pellets of earth. In *Z. nevadensis* and *N. cornigera* no trails made with squashes or petroleum ether extracts of the gut, contents of alimentary canal or rectum and drawn on a white card were followed, whereas similar trails drawn with extracts and squashes of the gland produced clear-cut trail-following. *Nasutitermes* does appear to follow a visible trail of fæcal droppings, however, but this is thought to be a consequent phenomenon and not the initial trail marker. When a scarcely visible, by-pass trail, made from the cleaned integument containing the gland, was drawn in competition with a natural trail that had reached the stage where it was quite visibly marked by fæcal droppings, both the workers and soldiers of *Nasutitermes* followed the by-pass in preference to the old trail.

The secretion from the gland has been shown to act as a trail releaser as well as marking the trail.

The trail-laying gland in *Zootermopsis* and *Nasutitermes* appears homologous to that described very briefly in *Kalotermes flavicollis* (Fabr.) by Grassi and Sandias[2], and by Montalenti[3], and in *Rhinotermes nasutus* (Perty) by Holmgren[4]. Grassé[5] has stated that the function of the gland in these species is unknown. In *Zootermopsis* the gland can empty through numerous small pores in the cuticle into a crude external reservoir formed by the almost complete overlapping of the fifth sternite by the preceding one. The nymphs of *Zootermopsis* are often seen dragging their abdomens along the ground when moving, thus bringing segment 5 in contact with the substrate, while the segments at the extremity of the abdomen are clear of the ground. The substance from the gland can thus quite easily escape from the reservoir on to the surface on which the insect is crawling.

All the observations and experiments on *Zootermopsis* were made on laboratory colonies which had been conditioned to live in constant illumination provided by a 'Daylight' fluorescent lamp.

A full account of this work and a description of the gland in *Zootermopsis* and *Nasutitermes* will be published elsewhere.

This work was supported by a grant-in-aid from Sigma Xi-RESA.

CYTOLOGY

Auto-Alloploid Nature of *Pennisetum squamulatum* Fresen

CYTOLOGICAL observations carried out in this laboratory on *Pennisetum squamulatum*, an East African[1] grass species, and on its F_1 hybrid[2] with pearl millet (*Pennisetum typhoides* Stapf and Hubb.), have suggested that *P. squamulatum* is an auto-allopolyploid.

Raman, Chandrasekharan and Krishnaswamy[3] reported that the species possessed $2n = 54$ chromosomes and that, during meiosis in the pollen-mother-cells, bivalents and quadrivalents (1 per cell) were formed. We re-examined meiosis in the pollen-mother cells of this species and observed the types of chromosome association which suggested the polyploid nature of this species (Table 1).

Table 1

	Quadrivalents	Trivalents	Bivalents	Univalents
Average frequency per cell	3·14	1·06	17·90	1·91
Range	1–8	0–2	11–23	0–4

Total cells observed : 36

During 1958 the cross, *P. typhoides* × *P. squamulatum*, was attempted on an extensive scale. For this, pollen from a single plant of *P. squamulatum* was dusted on a large number of ears of *P. typhoides* without emasculation. In 1959, 11 plants were raised in the field from the seed set on the male parent and about 600 plants from the seed set on the ears of *P. typhoides* used for crossing. Seven out of these 11 plants of *P. squamulatum* were examined cytologically, and all of them were found to possess

$2n = 54$ chromosomes, thus suggesting that, despite multivalent and univalent formation, the species was fairly balanced in respect of chromosome number. Of the plants raised from the seed set on the crossed ears, all but one were matromorphic. The single hybrid plant possessed $2n = 41$ chromosomes. During meiosis in the pollen-mother-cells of the hybrid 32 out of 36 clearly analysable cells showed 16 bivalents and 9 univalents; the remaining four cells showed 14–15 bivalents and 11–13 univalents per cell.

From the number of chromosomes and from the most frequent mode of chromosome association observed in the hybrid during meiosis it would appear that the hybrid plant arose from the union of an unreduced 14-chromosome *typhoides*-gamete with a normal 27-chromosome *squamulatum*-gamete. It would also appear that, of the 16 bivalents observed in the hybrid, 7 were derived from the *typhoides*-parent and 9 from autosyndetic pairing in the 18 out of the 27-chromosome complement derived from the *squamulatum*-parent. These observations further suggest that *P. squamulatum* ($2n = 54$) is an auto-allopolyploid[4] comprising in its somatic complement a 9-chromosome genome represented in the autotetraploid condition and another 9-chromosome genome in the diploid condition. Supporting evidence for such a view is obtained from the study of meiotic chromosome behaviour in *P. squamulatum*, where as many as 8 quadrivalents, out of the possible 9, were noticed in two cells.

A Simplified Method for the Study of Chromosomes in Man

Bottura and Ferrari[1] have described recently a rapid technique for the cytological preparation of human chromosomes, which involves intravenous injections of deacetylmethylcolchicine 2 hr. prior to a sternal marrow puncture. The marrow is then treated with hypotonic citrate, hydrolysed and stained. As they rightly point out, there are some advantages in this rapid technique over the short- or long-term tissue culture.

We have been employing similar techniques and have obtained good preparations of human chromosomes from dividing cells in the sternal marrow by giving the patient 1 mgm. of colchicine intravenously 1 hr. before the puncture. The material is then placed in 0·72 per cent w/v sodium citrate for 10 min., fixed in 3 : 1 (ethanol acetic), hydrolysed for 6 min. in *N* hydrochloric acid and stained in orcein (Fig. 1). Satisfactory preparations have also been made without giving the colchicine, relying only on the action of the hypotonic citrate; although, as would be expected, the contraction of the chromosomes is not then so well developed.

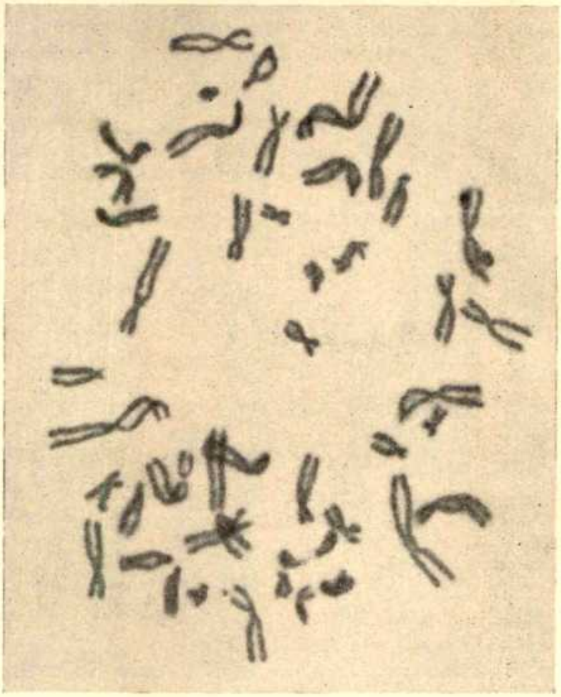

Fig. 1

These simple procedures are extremely useful for the rapid screening of human material. They would suffer perhaps from the disadvantage that they may not detect a chimærical situation. Their outstanding advantage, however, is the establishment of the *in vivo* situation in conditions such as leukæmia, where the results of culture techniques may not be truly representative.

Use of Induced Rooting in Cytological Studies

The common practice for the study of somatic chromosomes is to cut sections or squash the growing root-tips of a seedling. Occasionally successful preparations of somatic chromosomes have also been made from very young leaves and buds, but still in most cases root-tips continue to be favourite material for the study of somatic chromosomes. Seeds of wild plants, however, unlike those of the cultivated ones, are not always easily available, and this accounts at least in part for the fact that chromosome number in members of the former group have either not been determined or, if determined at all, reported from meiotic studies. This is evident from a cursory examination of the "Chromosome Atlas of Flowering Plants"[1]. The present work was started to find if these difficulties could be overcome by inducing adventitious root formation in isolated shoots and leaves by means of treatment with various growth-promoting substances.

The procedure to induce rooting in some of the species used as given here is more or less the same as that adopted by Gregory and Samantarai[2].

Stem and leaf of *Rauwolfia serpentina* Benth. and *Aralia filicifolia* L. have been treated with synthetic hormones, indole-3-acetic acid and naphthyl acetic acid. Several concentrations of these hormones were tried for treatment. In each concentration used, either stem cutting or the petiole of a leaf was placed for 24 hr. Then after thorough washing in running tap-water for ½ hr., the cutting or the leaves were transferred to specimen tubes containing tap-water which in turn were placed in a humid glass chamber. The materials were washed every 24 hr. in running tap-water and put back in the moist chamber. Indole-3-acetic acid of any concentrations could not induce rooting in *Aralia filicifolia* L., but some roots came out from the stem cutting of *Rauwolfia serpentina* Benth. after 25–30 days from the date of the treatment in 50 p.p.m. On the other hand, stem cuttings and a solitary leaf of the above two species, when treated with naphthyl acetic acid (10 p.p.m. for the solitary leaf and 50 p.p.m. for the stem), induced rooting after only 10 or 12 days. Thus it seems that naphthyl acetic acid is more effective for inducing rooting in these plants than indole-3-acetic acid, which is also evident from the fact that naphthyl acetic acid-treated materials developed copious and healthy roots, instead of solitary roots obtained from indole-3-acetic acid-treated materials. The stem and the leaf for such treatment should not be very old.

Squash preparations of the root-tips of the above species have been made after pre-treatment with 0·002 *M* 8-hydro-oxyquinoline for 3–4 hr. at about 18° C. The root tips were squashed either in 1 per cent propionic orcein or in acetic orcein. Before squashing, the root-tips were stained in a solution of 2 per cent acetic or propionic orcein and *N* hydrochloric acid in a ratio of 9 : 1 for 5 min. at 60° C. This staining procedure of keeping the root-tips for 5 min. at 60° C. in 9 : 1 acetic or propionic orcein and *N* hydrochloric acid has been found to give much better results, that is, uniform staining, than that given by Sharma and Mookerjee[3] in which the root tips are warmed on a burner. It is possibly due to non-uniformity of heating on a burner that the materials sometimes appear as under- or over-stained.

The chromosome counts of the species noted above show $2n = 24$ in *Aralia filicifolia* L., which is the same number as reported by Wanscher[4] and $2n = 20$ in *Rauwolfia serpentina* Benth. Since the somatic chromosome number of *Aralia filicifolia* L., determined here from induced roots, is the same as that reported by Wanscher from normal roots, it appears that growth-promoting substances do not in any way disturb the chromosome number and morphology.

My sincere thanks are due to Prof. R. P. Roy and Dr. J. P. Sinha, Botany Department, Patna University, for their encouragement and help.

GENETICS

New Recurrent Series in Inbreeding Phenomena

A number of recurrent series have been found in phenomena related to inbreeding. A new series is represented by the sequence of the values of f'_m (the mean coefficient of inbreeding for sex-linked genes[1] in a strictly panmictic population model, as defined by Freire-Maia and Freire-Maia[2]), from sib matings through the subsequent simple full degrees of consanguinity (uncle–niece plus aunt–nephew, $UN + AN$; first cousin, $1C$; first cousin once removed, $1\frac{1}{2}C$; second cousin, $2C$; etc.). This series is as follows: 1/4, 3/16, 5/64, 11/256, 21/1,024, 43/4,096, 85/16,384, . . . (Fig. 1) (cf. Freire-Maia and Freire-Maia[2] and unpublished work, and Freire-Maia and Marçallo[3] for these terms). Knowing two consecutive values, the following value may be calculated by the formula:

$$x'_n = \frac{1}{4}\left(x'_{n-1} + \frac{1}{2}x'_{n-2}\right)$$

The general solution for this equation is:

$$x'_n = \frac{1}{3}\left(\frac{1}{2}\right)^n - \frac{1}{12}\left(-\frac{1}{4}\right)^n \qquad (1)$$

Excluding x_0, which corresponds to sib mating, and x_1, corresponding to $UN + AN$, all the other consanguineous matings (that is, the cousin matings) have their positions in the series given by multiplying their respective abbreviated representation (1, 1½, 2, 2½ . . .) by 2. Third cousins once removed ($3\frac{1}{2}C$) are, for example, the seventh term.

The sequence of the values of f (Wright's coefficient of inbreeding for autosomal genes) for the offspring of the same above-mentioned consanguineous unions also forms a recurrent series (1/4, 1/8, 1/16, 1/32, 1/64 . . .) which is also a geometric progression (Fig. 1). Any one of its terms may be calculated according to the formula:

$$x_n = \frac{1}{4}\left(\frac{1}{2}\right)^n \qquad (2)$$

In these two recurrent series, the limiting value of x'_n and x_n as $n \to \infty$ is 0. This limit is approached in an oscillatory way by x'_n in the first series (cf. formula 1).

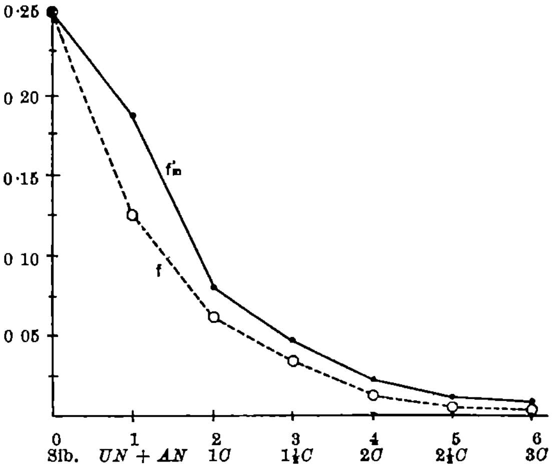

Fig. 1. The first values of f and f'_m

The ratio of formula (1) to formula (2) is :

$$x'_n = \frac{4}{3} - \left[\frac{1}{3}(-1)^n\right]\left(\frac{1}{2}\right)^n$$

which is the general formula for any term of a new recurrent series. The limiting value (4/3) is rapidly approached in an oscillatory way (Fig. 2) similar to that found by Jennings[4] for the equlibrium of sex-linked genes in random mating populations. In cases of distant consanguinity, f'_m may be accepted as being roughly equal to $1 \cdot 33\ f$. The terms of this oscillating series are : 1, 3/2, 5/4, 11/8, 21/16, 43/32, 85/64, 171/128, 341/256, . . . Knowing two consecutive terms :

$$x_n = \frac{1}{2}(x_{n-1} + x_{n-2})$$

The above-mentioned oscillatory approach is due to the fact that the first series is composed of alternating terms of two other series—one for the consanguinity between persons belonging to the same generation (sibs and cousins of the nth degree) and the other for the consanguinity of persons belonging to different generations ($UN + AN$ and cousins of the nth degree once removed) (Fig. 2).

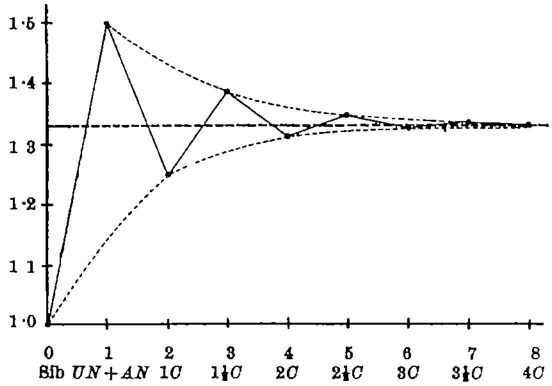

Fig. 2. Oscillatory approach of the ratio f'_m/f to the limiting value 4/3 as $n \rightarrow \infty$

Each term of the series for persons belonging to the same generation may be found as follows :

$$x_n = \frac{5}{16}x_{n-1} - \frac{1}{64}x_{n-2}$$

yielding the general solution :

$$x_n = \frac{1}{3}\left(\frac{1}{4}\right)^n - \frac{1}{12}\left(\frac{1}{16}\right)^n$$

for initial values $x_0 = 1/4$ and $x_1 = 5/64$.

Each term of the series for persons belonging to different generations may be calculated as follows :

$$x_n = \frac{5}{16}x_{n-1} - \frac{1}{64}x_{n-2}$$

yielding the general solution :

$$x_n = \frac{1}{6}\left(\frac{1}{4}\right)^n + \frac{1}{48}\left(\frac{1}{16}\right)^n$$

for initial values $x_0 = 3/16$ and $x_1 = 11/256$.

This investigation was supported by grants from CAPES, the Rockefeller Foundation, the National Research Council of Brazil, and the Research Council of the University of Paraná.

We are indebted to Dr. David Carneiro, jun., for his valuable suggestions.

Genetic Recombination in Bacteriophage ΦX 174

RECENTLY, Tessman[1,2] and Sinsheimer[3] suggested that the deoxyribonucleic acid of ΦX 174 is one-stranded in contrast to the double-stranded deoxyribonucleic acid of other phages. From this point of view it seemed interesting to investigate genetic recombination in this phage. Tessman[4] achieved recombination in bacteriophage S 13 by stimulation with ultra-violet irradiation of free virus particles. (S 13 is serologically related to ΦX 174 and similar in other properties.) The frequency of recombinants found after ultra-violet irradiation was of the order of 0·1 per cent. In other work[5] without irradiation, no recombination could be detected.

A selective system for host-range recombinants, similar to the negative host-range system in T2 (ref. 6), could be developed in ΦX 174 : *E. coli C* were plated on colour-agar plates (Bresch and Trautner[7]) with an excess of ΦX 174 and a resistant strain C_a was isolated. A host-range mutant of ΦX 174 against C_a was then selected and called *Ha*. By repeating these procedures a second-step bacterial mutant C_{ab} and phage mutant *HaHb* were obtained. A third step resulted in a triple bacterial mutant C_{abc} and a triple phage mutant *HaHbHc*. This *HaHbHc* stock was treated with nitrite, which induces mutations by affecting the nucleic acids[8]. Negative host-range mutants (revertants) appear as turbid plaques on mixed indicator *C* plus C_{abc}.

Fifteen such revertants (numbered 1–15) were collected and crossed to each other and to the one-step (*Ha*) and two-step host-range mutant (*HaHb*). Many of these crosses resulted in recombinants, able to grow on C_{abc}. In Table 1 the recombining crosses are represented by + and the non-recombining by −. The fraction of recombinants was between 1×10^{-4} and 6×10^{-4}. The background of mutation to a C_{abc} lysing type, controlled by the 'self-crosses', was in all cases less than 10^{-7}.

From Table 1 the revertants can be placed in three groups according to whether the back mutation occurred either in *Ha*, *Hb* or *Hc*. Two exceptions (Nos. 2 and 3) seem to show reversions at two sites. A preliminary quantitative evaluation of the recombination data suggests a linear order *HaHbHc*, where the distance *Ha–Hb* is about half the distance *Hb–Hc*.

Australian Aborigines and Genetics

PROF. A. A. ABBIE's statements[1] concerning two of my papers[2,3] on the genetics of the Australian aborigines cannot be allowed to pass unanswered. Prof. Abbie admits that he is not a geneticist, yet he throws doubt on genetical methods of racial study, even suggesting that nearly three months in Australia was insufficient time for me to obtain reliable results. He is unwilling to recognize that anatomy can only make *comparisons* between racial types, while genetical methods of family study in crosses give an *analysis* of racial differences and are thus of far greater significance. His thesis appears to be that the aboriginal population of the whole continent is a unit, and that all the evidence which shows the presence of mixed elements must be resisted or denied.

Prof. Abbie makes various comparisons of means and ranges in different local populations, for example, in stature, but he makes the long outmoded assumption that these are mere variations from a mean. He fails to see that measurements are of little value unless there is some understanding of the method of inheritance of the differences involved. Much evidence shows that stature in various races of mankind depends in part on multiple genes which are cumulative in effect, the number of such genes being probably a small one for each racial character. This applies both to stature and hair form.

Those who see the limitations of Prof Abbie's anatomical methods should advocate the genetical approach to race studies; but unfortunately very few, at present, have the necessary combination of genetical and anthropological knowledge and experience.

As regards the Mongolian (better sacral) spot, one would be surprised to find it in the aborigines in view of all their other racial characters, which are mainly archaic Caucasoid except the darker skin colour.

Regarding the dwarf element in certain tribes of Queensland, Prof. Abbie does not mention that my conclusions are a confirmation of those of Tindale and Birdsell[4] that these people are a remnant of a Negritoid type which was pushed down into Tasmania (with a limited amount of crossing with Australian aborigines) when the latter entered Australia from the north and moved south. There are few cases of early racial migration for which the evidence to unprejudiced minds is so unequivocal. Yet Prof. Abbie not only denies it but says that this is "a fair example of ignoring facts to push a hypothesis". He achieves this by referring to the fact, stated by Tindale and Birdsell[4] as well as myself[3], that some of the Queensland dwarfs have a yellowish skin colour. He is evidently unaware of the elementary fact that this is simply due to dilute melanin. The situation is similar regarding hair form, where a few multiple genes for curly hair will account for the dispersal of this character as an occasional occurrence through the continent of Australia.

Regarding head form, Prof. Abbie ignores the extensive genetic results of my work from the study of families of mixed descent (Aborigine × White) in three generations, mainly at Alice Springs and Darwin, which breaks new ground and shows the remarkable genetic nearness of these aboriginals to the archaic Caucasoids of Europe.

R. RUGGLES GATES

46 Lincoln House,
Basil Street,
London, S.W.3.

[1] Abbie, A. A., *Nature*, 187, 375 (1960).
[2] Gates, R. Ruggles, *Acta Genet. Med. et Gemell.*, 9, 7 (1960).
[3] Gates, R. Ruggles, *Z. Morph. Anthrop.*, 50, 150 (1960).
[4] Tindale, N. B., and Birdsell, J. B., *Rec. S. Aust. Mus.*, 7, 1 (1941).

I WISH to make the following comments on Prof. Ruggles Gates's communication.

I freely admit to being an old-fashioned anatomist employing an archaic methodology; this, however, has the minor advantage of dealing in facts, some of them even measurable.

The close association of Australian aborigines with some basic 'Caucasoid' stock has long been widely accepted. I mentioned our failure to find a 'sacral spot' purely in passing, because some observers had previously claimed that it existed. Whether or not that had any relationship to presumed 'Caucasoid' affinities of the aborigines is beside the point.

I apologize to Prof. Ruggles Gates for any seeming discourtesy over his observation that the Queensland aborigines he examined have a yellowish skin, but I must point out that he laid himself open to adverse comment. He cites "a tendency toward yellowish brown skin colour" as characteristic of "Barrineans". I said that Prof. Ruggles Gates knew that in all aborigines the skin fades to a yellowish colour when protected from direct sunlight; this, of course, will occur in the rain forest of north-east Queensland. I am quite well aware that the yellowish colour is probably due to dilute melanin, as I had indicated in an earlier paragraph. But if any aborigine can fade to a yellowish colour, such colouring cannot be considered ethnically distinctive within Australia.

University of Adelaide.

SOIL SCIENCE

Microbiological Changes in Freshly Moistened Soil

It is well known that when a dried soil is moistened there is a burst of respiratory activity. Drying, in some way, renders a part of the soil organic matter soluble and it has been considered that the decomposition of this fraction by micro-organisms partly accounts for the high respiration-rates recorded. The composition of this soluble material has not been fully determined, but it has been shown to contain appreciable amounts of several amino-acids[1]. In these circumstances the development of a specialized zymogenous population might be expected. Indirect evidence for the existence of such a population has been provided by Chase and Gray[2]. They made a detailed analysis of the respiration of freshly moistened soils and concluded that their results could be best interpreted by assuming that two major microbial populations were involved, namely, one with a low rate of metabolism—the autochthonous population—and the other with a very high rate—the zymogenous population.

Observations made recently on the behaviour of the bacteria in an East African soil (Kikuyu red loam) provides direct evidence for this interpretation. Soil which had been dried was re-moistened to field capacity and maintained at 25° C. Rate of carbon dioxide production and bacterial numbers were recorded at 3-hourly intervals for a period of 36 hr. Carbon dioxide was determined in the macrorespirometer devised by Birch and Friend[3] and bacterial numbers by direct cell counting[4]. Note was taken of the morphology of all cells scored and it was found that the two main cell types (cocci and rods) showed marked differences in their distribution over the 36-hr. period. From Fig. 1 it can be seen that a comparatively small increase in coccoid forms occurred early, their numbers then remaining at a fairly steady value. Rods, on the other hand, showed no increase until after 12 hr., when their numbers increased rapidly to a maximum at 24 hr.

It will be recalled that Winogradsky[5] considered the autochthonous flora of the soil to be composed almost exclusively of cocci and very short rods, whereas the zymogenous flora comprised spore-formers and long rods. The present results can be interpreted as showing that the rods constitute the zymogenous part of the population and, in fact, are responsible for the greater part of the flush of carbon dioxide. Although numerically they do not at any time constitute more than 50 per cent of the total population, their size in comparison with the cocci is such that they must, during their brief period of growth, constitute the greater part of the active cellular material in the soil. Moreover, it is well established that maximum physiological activity occurs during the lag and early log phase in the growth of a bacterial culture and it is clear that in the present instance maximum carbon dioxide production coincides with this part of the growth curve of rods rather than with the point of maximum number.

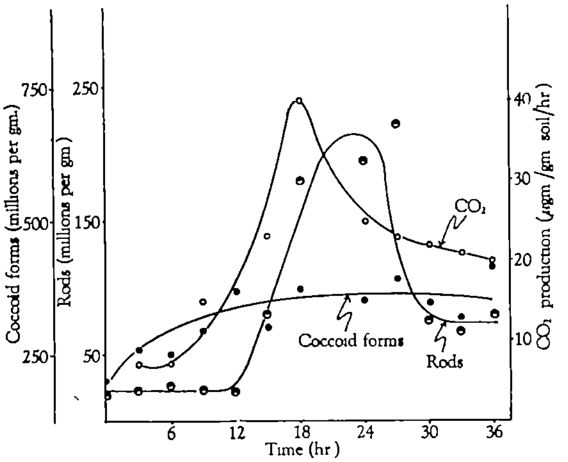

Fig. 1. Carbon dioxide production (○) and development of bacterial populations in moistened soil. ●, Coccoid forms; ⊖, rods

This work, which is being continued and will be reported more fully elsewhere, was undertaken when one of us (E. G.) was in receipt of a travelling grant from the Colonial Office.

MISCELLANY

Letter from Erasmus Darwin to Jonas Dryander

The following extract from a letter of Erasmus Darwin to Jonas Dryander seems worth noting. The letter is in a small collection in the Department of Botany, British Museum (Natural History) labelled "Dryander Correspondence".

"Derby, May 21–87

. . . I must now beg another favor of you, which is to give your suffrage to my Son, Dr. Robt. W. Darwin, whom I wish to be a member of the Royal Society, which might add new spirit to his industry in philosophical pursuits ; & should be much obliged to you to present my best compl. to Dr. Blagden, when you see him, & ask for my Son the same favor from him. Mr. Ch. Greville has spoken to Sr. Joseph Banks in his favor, whom I should otherwise have troubled with a letter on this account. Doctor Robt. Darwin is settled in Shrewsbury, where he meets with very great encouragement, having been concern'd for near fifty patients in the first six months ; & I dare say will make a very useful member of the Society."

Robert Darwin "began to practise before he was twenty-one years old" (Charles Darwin, *The Autobiography*).

John Ramsbottom

Richmond,
Surrey.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 6

University of London (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 5.15 p.m.—Mr. R. W. Young · "The University and the Grammar School".*

British Society for the History of Science (in the London Planetarium, Marylebone Road, London, N.W.1), at 5.30 p.m.—Mr. Leonard Clarke : "Greek Astronomy and Its Debt to the Babylonians".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. E. Humphrey : Presidential Address.

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. James Taylor : "The Modern Chemical Industry in Great Britain". (Last of three Cantor Lectures.)

Society of Chemical Industry, London Section (joint meeting with the London Section of the Royal Institute of Chemistry, at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. H. H. Chambers : "Fuel Cells".

Society of Instrument Technology, Data Processing Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Prof. J. E. Parton and Mr. A. Rose : "The Universal Decision Element".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. J. Ward-Perkins : "Etruria's Past".

Tuesday, February 7

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Meeting on "Alternative Nitrogen Fertilizers".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. W. G. Chaloner : "Wandering Continents and Fixed Ideas—a Discussion of the Evidence for Continental Movement".*

British Institution of Radio Engineers (joint meeting with the Electronics Group of the Institute of Physics, at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 2.15 p.m.—Meeting on "Tunnel Diodes".

British School of Athens (at the Royal Geographical Society· 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. Sinclair Hood : "Excavations at Knossos (Crete), 1960".

Institution of Electrical Engineers, Measurement and Electronics Sections (at Savoy Place, London, W.C.2), at 5.30 p.m. —Mr. E. M. Bradley : "Magnetic Properties of Thin Films for Computing Devices".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. Knox : "Contrasting Patterns of Drug-Resistance in Tubercle Bacilli and Staphylococci".* (Eighth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Royal Institute of Chemistry (joint meeting with the Sir John Cass College Chemical Society, at the Sir John Cass College, Jewry Street, London, E.C.3), at 6.30 p.m.—Prof. B. C. L. Weedon : "Organic Reactions in Strong Alkalis".

Wednesday, February 8

Institute of Physics and the Physical Society, Low Temperature Group (at 47 Belgrave Square, London, S.W.1), at 2.30 p.m.—Meeting on "Ultrasonic Absorption and Attenuation in Metals at Low Temperature".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. Rodney Perry : "The Timber Industry".

Eugenics Society (at Manson House, 26 Portland Place, London, W.1), at 5 p.m.—Sir Robert Platt, Bt. : "Inherited Disease in Man" (The Galton Lecture.)

British Institution of Radio Engineers, Computer Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. G. Emery . "Perseus, a Medium-scale Data Processing System".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. F. G. E. Pautard : "The Molecular Biology of Calcified Tissues".* (Second of three lectures on "The Scientific Basis of Dentistry" organized by the British Postgraduate Medical Federation.)

Women's Engineering Society, London Branch (at Hope House, 45 Great Peter Street, Westminster, London, S.W.1), at 7 p.m.—Mr. L. J. Carter : "Space Exploration".

Thursday, February 9

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. R. A. French : "Russian Rivers in the Service of Man".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. J. Latham and Mr. B. J. Mason : "Electric Charge Transfer Associated with Temperature Gradients in Ice" and "Generation of Electric Charge Associated with the Formation of Soft Hail in Thunder-clouds".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. P. J. Grubb : "Alpine Plant Communities in Southern Jugoslavia".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. L. H. Collier : "Trachoma and Inclusion Blennorrhoea".* (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.

Chemical Society (at Burlington House, Piccadilly, London, W.1 at 7.30 p.m.—Meeting for the reading of Original Papers.

Thursday, February 9—Monday, February 27

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7)—Greenland—an Exhibition.

Friday, February 10

Association of Applied Biologists (at the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10.40 a.m.—Papers on "Recent Research on Plant Virus Diseases".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir George Sutherland, F.R.S. : "Diamonds".

Saturday, February 11

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. William Fagg · "The Art History of Benin, Nigeria".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer (preferably skilled in or possessing a knowledge of mass spectroscopy as applied to chemical problems) in Physical Chemistry—The Registrar, The University, Leeds 2 (February 14).

Imperial Chemical Industries Fellows for Research in various branches of Chemistry, Chemical Engineering, Engineering, Technology, Physics, and allied subjects—The Registrar, The University, Manchester 13 (February 14).

Turner and Newall Research Fellows in Engineering, Inorganic Chemistry, Physics and allied subjects—The Registrar, The University, Manchester 13 (February 14).

Senior Assistant Observer (with a good honours degree in mathematics, physics or astronomy, and some experience of research in astrophysics)—The Director, Observatories, The University, Madingley Road, Cambridge (February 15).

Technical Officer (with a degree in physics or engineering and a good practical knowledge of electronics), for research into photoelectric photometry by pulse counting techniques—The Director, Observatories, The University, Madingley Road, Cambridge (February 15).

Demonstrator (with a degree in science or agricultural science) in Agronomy at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, February 15).

Lecturer (physicist, preferably with an interest in observational science) in the Department of Meteorology—Professor of Meteorology, Imperial College of Science and Technology, London, S.W.7 (February 20)

Assistant Lecturers (2) in Biochemistry—The Registrar, Manchester College of Science and Technology, Manchester 1 (February 25).

Assistant Lecturer or Lecturer (graduate in microbiology, bacteriology, botany, biochemistry or cognate fields) in Microbiology—The Registrar (Room 22, O.R.B.), The University, Reading (February 28).

Lecturer or Assistant Lecturer in the Department of Mathematics at Makerere College (The University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (February 28).

Scientific Officer (with a first- or second-class honours degree in mathematics with statistics, or a diploma in statistics) in the Statistics Section for duties mainly concerned with the design and analysis of field experiments—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (February 28).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry or Physics—The Registrar, University College, Dublin (March 7).

Lecturer (with an honours degree in botany or agricultural botany, postgraduate research and training in plant pathology, and preferably an interest in host-parasite relations); and an Assistant (with an honours degree in botany or agricultural botany, training in plant pathology, and preferably an interest in virus diseases) in the Department of Botany—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (March 11).

Lecturer or Assistant Lecturer in Statistics—Head of the Department of Mathematics, Imperial College of Science and Technology, South Kensington, London, S.W.7 (March 24).

Assistant Keeper in the Department of Botany—The Secretary, National Museum of Wales, Cardiff (April 1).

Research Students (geology graduates) in Geochemical Prospecting—Dr. Webb, Geology Department, Imperial College of Science and Technology, South Kensington, London, S.W.7 (June 1).

Agricultural Chemist (with a good honours degree in agricultural chemistry or chemistry with at least two years postgraduate research experience in agricultural chemistry) in Kenya, to take charge of research projects into soil and plant nutrition problems of coffee—

The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/7/050.

ANIMAL GENETICIST, to undertake research in quantitative genetics with the ultimate objective of obtaining basic information needed for an understanding of inheritance of economic traits in livestock and poultry; a FOREST BIOLOGIST (PLANT or FOREST PATHOLOGIST), to design, conduct and supervise research in diseases of forest nursery stock; and a QUANTITATIVE GENETICIST (MATHEMATICIAN or STATISTICIAN), to conduct research into methods appropriate for dealing with problems in quantitative genetics, with the Canadian Department of Agriculture—Civil Service Commission of Canada, Ottawa, Canada, quoting Ref. 61–2201.

EDITORIAL ASSISTANT (with a university degree in science or technology, and preferably at least two years postgraduate experience in science or industry)—The Manager, *Nature* Office, Macmillan and Co., Ltd., St. Martin's Street, London, W.C.2.

GRADUATE ASSISTANTS (qualified to pursue M.Sc. and Ph.D. work in chemistry)—The Chairman, Department of Chemistry, McMaster University, Hamilton, Ontario, Canada.

HEAD (with good academic qualifications in science, and preferably teaching, industrial and administrative experience) OF THE DEPARTMENT OF SCIENCE—The Principal, Cambridgeshire Technical College and School of Art, Collier Road, Cambridge.

PHYSICISTS, ENGINEERS and MATHEMATICIANS, Scientific Officer or Senior Scientific Officer grade (with a first- or second-class honours degree or equivalent in physics, electrical engineering or mathematics, and at least three years postgraduate experience for Senior Scientific Officer grade) at the Radio Research Station, D.S.I.R., Ditton Park, Slough, to investigate the upper atmosphere and the space between the Earth and the Sun, with particular reference to the propagation of radio waves through these regions, and associated problems of terrestrial and space communications—The Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.581/0A.

RESEARCH WORKER (BIOCHEMIST or CHEMICAL PHARMACOLOGIST, preferably with Ph.D. or equivalent experience), to investigate the biochemical actions of drugs currently used in the treatment of mental illness—The Director of Clinical Research, Crichton Royal, Dumfries.

SENIOR LECTURER or LECTURER (with high academic qualifications, preferably in metallurgy, coupled with practical experience of the techniques and the engineering utilization of welding) IN WELDING TECHNOLOGY—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

SENIOR TECHNICIAN FOR WORK IN THE BACTERIOLOGICAL DIVISION at Connaught Hospital, Walthamstow, London, E.17—The Secretary, Forest Group H.M.C., Langthorne Road, London, E.11.

SOIL SURVEYOR (age 26–40, with a degree in natural science or geography, with two years' postgraduate training or experience in soil survey work) in Sarawak, to carry out soil surveys—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD. 63/24/07.

CONTROL OF UNIVERSITY BUILDING DEVELOPMENT

ON December 20, the Prime Minister announced in the House of Commons that Lord Robbins, *professor of economics in the University of London*, had accepted the chairmanship of the provisional committee to inquire into higher education in Britain. The full composition of the Committee has not been announced, but its terms of reference were given as follows:

"To review the pattern of full-time higher education in Great Britain and in the light of national needs and resources to advise Her Majesty's Government on what principles its long-term development should be based. In particular, to advise, in the light of these principles, whether there should be any changes in that pattern, whether any new types of institution are desirable and whether any modifications should be made in the present arrangements for planning and co-ordinating the development of the various types of institution."

The long-term development of universities, colleges of advanced technology, certain other colleges of further education and teacher-training colleges, Mr. Macmillan added, would be within these terms of reference. The Government, he said, is trying to get a very broad representation on the Committee and, by doing so, to deal with all the possible groups that should be considered.

These terms of reference clearly permit the Committee to consider the question of university expansion not in isolation but in relation to the educational system as a whole. It could, for example, comment on the merits or demerits of dealing with higher technological education separately from university education, and could probe into the question of relations between the University Grants Committee and the Ministry of Education. It is true that the Robbins Committee is not expected to publish its findings for two or three years, and the University Grants Committee, which is already discussing with the Treasury the increase in non-recurrent grants entailed by university expansion, is expected by this autumn to submit to the Chancellor of the Exchequer its estimate of what the universities will need from Parliament during the next quinquennium—1962–67. The limit to that immediate expansion is likely to be set by the availability of academic staff and capital resources, and the Robbins report should be available when the questions of how far and where the university system should be further expanded, what are its purposes and what should be its relation qualitatively and quantitatively to the educational system of the country as a whole, require decision. Moreover, in the meantime there may be available a good deal of guidance on such matters as curricula, university entrance and the nation's demands for particular categories of trained man-power and woman-power, and supporting auxiliaries.

Two matters that bear closely on the expansion or modification of the university system in relation to national needs have recently received some attention. The first relates to the financial aspect of expansion. When the report of the Gater Committee, which inquired into the methods used by the universities in contracting and in recording and controlling expenditure from non-recurrent grants, was published in 1956, it was contemplated that the application by the universities of the Committee's recommendations would be reviewed at a later date, and in 1959 the University Grants Committee invited Sir Arthur Rucker to undertake this review. Sir Arthur's report has now been published*, and confirms that, with minor exceptions, the procedures recommended by the Gater Committee are being followed. The University Grants Committee accepts Sir Arthur Rucker's recommendations regarding these exceptions, as well as recommendations for further amendments in the procedure both of the universities and of the University Grants Committee itself.

Sir Arthur Rucker emphasizes first both the magnitude of the building programme of the universities seen as a whole and the success already being achieved. As already announced, up to the end of 1963 the programme provides for an increase in student population from 85,000 in 1955–56 to 135,000 in the second half of the 1960's, and if the further expansion to 170,000 already under discussion is realized, the student population of the universities will have been doubled within a relatively short period of years. On January 25, the Chancellor of the Exchequer, in a written answer in the House of Commons, indicated that further expansion had been approved. He had now authorized the University Grants Committee, he stated, to increase the Government-financed university building programmes starting in the calendar years 1962 and 1963 from the present £15 million to £25 million in each year, and for the years 1964 and 1965 he had authorized the Committee to invite the universities to make building plans on a basis of starts of £30 million in each year. The rate at which these plans can be executed must depend on the general state of the national economy and on such factors as building costs; but Mr. Selwyn Lloyd did not anticipate that the figure ultimately authorized would be less than £25 million a year, and he hoped it would be up to £30 million in each year. This large addition to the resources of the universities should, he added, assist materially in the practical task of accommodating the increased numbers of students who would be coming forward in the second half of this decade, and it would be compatible with further development after 1965 to expand the university population to about 170,000 by the early 1970's.

Controversy, occasionally acute, over the merits of individual university buildings, should not be allowed to obscure the truth that a period of great university expansion is in progress in Britain, and that buildings well suited to its needs will have been provided when the programme of grant-aided buildings has been completed. The real questions are rather where such university expansion should take place, the extent to which such expansion is desirable, particularly in relation to the simultaneous expansion of technological education generally, and to the training of the vastly greater numbers of technicians and craftsmen who are essential if effective use is to be made of the services of the scientists, technologists and other highly trained products of the universities.

---

* University Grants Committee. Methods used by Universities of Contracting and of Recording and Controlling Expenditure. Pp. 28. (Cmnd. 1235.) (London: H.M. Stationery Office, 1960.) 1s. 6d. net.

All the universities use the Gater Report as their guide in defining the procedures to be used in carrying out their building programme, and for the most part the procedures recommended were already in force. Where this was not so, they have, with a few minor exceptions, been adopted and remain in use. Like the Gater Committee, Sir Arthur Rucker found no evidence that grants-in-aid of 90–100 per cent weakened the sense of financial responsibility on the part of the universities; but there are naturally differences of opinion on the standards and costs appropriate to particular buildings or types of building. It is, however, not always easy to decide the extent to which non-recurrent grants for buildings can or should be supplemented by universities from their own resources. The University Grants Committee has already emphasized the value and importance to university life of the generous gifts which universities receive from foundations, firms and individuals, more particularly as a proof of public confidence in the work which the universities are doing in advancing scientific knowledge and providing the trained man-power on which the future of Great Britain depends; and Sir Arthur points out that, if such gifts are to be encouraged, universities must have a reasonable degree of freedom to spend them in the way which they consider most useful.

Some expenditure and some embarrassment in planning would have been avoided, he notes, if the present targets for expansion could have been fixed at the beginning of the building programme instead of by later increases; but now that all universities have established control procedures on the lines recommended by the Gater Committee, Sir Arthur considers it unnecessary for the University Grants Committee to review in detail the expenditures under minor works allocation: such expenditure should be left to the discretion of the university. Again, he emphasizes the need for great care in examining comparisons of costs, as the costs of university buildings, even when intended for similar purposes, vary widely; and in his view it is in the interest of economy that every reasonable opportunity should be taken to acquire land likely to be needed for development, even when no immediate use is in prospect. An Architect's Division with professional staff has already been created in the office of the University Grants Committee, and with its aid the Committee is seeking to collect information and statistics on all aspects of university building, to examine space requirements and to analyse costs. A beginning has been made with the definition of space standards and limits of costs for various types of university building.

Apart from these general observations, Sir Arthur Rucker is concerned mainly with the application of the recommendations of the Gater Committee. Of even greater interest, however, are the comments which he makes on developments since that Committee reported, and the conclusions and recommendations arising out of those comments. The great expansion of the building programme makes it even more essential that building procedures should provide effective safeguards against waste, extravagance or other abuse; whereas in 1954–55 grants paid for building works amounted to £4,674,545 and for professional fees to £306,242, in 1959–60 the corresponding figures were £13,693,621 and £1,959,775. The Chancellor's statement on January 25 increased this figure of £15 million to £25 million in 1962 and 1963 and probably to £30 million in the following two years. Reference has already been made to the way in which the establishment of an Architect's Division under the University Grants Committee is assisting the collection and analysis of information and statistics relating to university buildings, and the definition of cost limits and space standards; and Sir Arthur's inquiry has confirmed the desirability of defining, so far as this is possible, the appropriate limit of cost for a university building at a very early stage in planning. The special requirements of university buildings must nevertheless not be ignored, and procedures for defining limits of cost must be sufficiently flexible to take account of those requirements.

There are four stages in the present procedures of the University Grants Committee for the approval of building grants, and Sir Arthur recommends that they should be so timed that the second stage—submission of Schedule I—takes place two and a half to three years in advance of the date of giving out to tender. Since the universities were informed in 1958 of the buildings which they could expect to start in each of the years 1960–63, this should now be practicable. He also considers that in so far as it is found possible to define cost limits for university buildings, it should be feasible for the University Grants Committee to simplify the present procedures and normally to dispense with much of the detailed examination of plans and estimates. At present, limits of cost are defined for halls of residence and, in part, for scientific buildings; but particularly in respect of scientific buildings, Sir Arthur again stresses the need for flexibility and taking special circumstances and varying needs into account at all stages of planning.

Sir Arthur Rucker was not concerned with standards themselves, but only with the procedures for their definition and application; but he is concerned to emphasize that the procedures under which building grants are approved by the University Grants Committee must be devised and applied in close and constant consultation with the universities. This essential consultation would be facilitated, he suggests, if the University Grants Committee were to appoint a Buildings Sub-Committee with membership drawn mainly from the universities. Whatever the arrangements for consultation may be, it is essential that there should be a clear understanding between the members and officers of the University Grants Committee and the universities and their officers at all levels of staffing. If procedures for the control of grant-aided expenditure are to be successful, the present excellent and harmonious relations between the University Grants Committee and the universities must be maintained.

With these concluding words Sir Arthur Rucker endorses, like the Gater Committee, the essential soundness of the present procedures for controlling the expenditure of these large sums of public money, and also, like that Committee, firmly rejects the attack on the system which the Public Accounts Committee maintained for more than a decade. While, however, it is to be hoped that the Public Accounts Committee will not re-open that issue, this further tribute to university administration indicates the outstanding importance of efficient government of universities at the present time, and further, the necessity for securing public understanding of the work which universities are doing and confidence in the ability with which the universities are meeting the demands made upon them. It is clearly within the terms of reference of the Robbins Committee to inquire into the adequacy of the present pattern of university government if it thought fit; but on this second issue, it must suffice to observe here that, while the present arrangements for university administration have come so well out of the searching inquiry to which the Gater Committee and Sir Arthur Rucker have subjected them on the financial side, it is no less important that these arrangements should be adequate to meet the demands which university expansion in Britain is making on them in many other ways.

A UNIFIED TREATMENT OF MODERN OPTICAL THEORY

Principles of Optics

Electromagnetic Theory of Propagation, Interference and Diffraction of Light. By Prof. Max Born and Prof. Emil Wolf. With contributions by A. B. Bhatia, P. C. Clemmow, D. Gabor, A. R. Stokes, A. M. Taylor, P. A. Wayman and W. L. Wilcock. Pp. xxvi+803. (London and New York: Pergamon Press, 1959.) 120*s*. net.

It is quite impossible to do justice to a work of such depth and scope as *Principles of Optics* within the confines of an ordinary review; even to list the contents would require several pages. A few general remarks will therefore be made in the hope of tempting any reader who has not already done so to look at a copy for himself as soon as possible.

Perhaps the most striking impression that one obtains is of completeness. The scope is best described in the words of the authors' preface: ". . . our discussion is restricted to those optical phenomena which may be treated in terms of Maxwell's phenomenological theory. This includes all situations in which the atomistic structure of matter plays no decisive part. The connection with atomic physics, quantum mechanics and physiology is indicated only by short references wherever necessary." Within this framework it would be difficult to find any aspect of modern optical knowledge that is not covered. But the impression of completeness extends to the treatment as well as to the subject-matter. Compare for a moment the following three brief extracts. On page 111 the equation:

$$(\text{grad}\ \mathcal{S})^2 = n^2$$

is derived, n being the refractive index and $\mathcal{S}$ the eikonal, followed by the statement "it is the basic equation of geometrical optics". On p. 163 we read "When the (two thin) lenses are in contact equation ... may be written in the form $P = P_1 + P_2$ so that the power of the combination is then simply equal to the sum of the powers of the two lenses". Finally, on p. 249 we read "In a photographic enlarger ($\varphi \sim 20°$), large sources (frosted bulbs or cold-cathode tubes) often provide reasonably efficient illumination. In a cinematograph projector ($\varphi \sim 5°$) requiring maxium brightness, an electric filament is suitable". It will be seen that the most advanced mathematical treatment, the familiar working formulæ and the practical implications all find a place.

Principles of Optics is valuable as a work of reference; but it may be that its value in showing the interdependence and essential unity of the different approaches may be even greater. Honours students in physics will find here the often-missing links between theoretical and experimental studies. It is interesting to note that even in some of the most mathematical sections the style is clear and vivid. In the early stage of the development from Maxwell's equations we read "Within this layer construct a small near-cylinder bounded by a stockade of normals to T, roofed and floored by small areas δA, . . .". The diagram is almost unnecessary.

Students should be warned, however, that this is emphatically a book for studying rather than reading. The plan of each section is to begin with the most general theory and proceed later to particular practical cases. A certain amount of searching may therefore be necessary to find some of the more familiar material. For example, the chapter entitled "Foundations of Geometrical Optics" begins with the derivation of the eikonal equation already mentioned and we do not meet Snell's law and the elementary laws of reflexion until seventeen pages later.

There have been so many text-books on optics that it is quite thrilling to find so much that is new in both presentation and material in one volume. Its only disturbing feature is that after spending even a very short time in study one is made to realize the vast depth of the subject and the shallowness of one's own understanding of it.

C. A. Taylor

THE FOURTH INTERNATIONAL CONGRESS OF BIOCHEMISTRY

Proceedings of the Fourth International Congress of Biochemistry

Vienna, 1–6 September, 1958. Vols. 1–15. (London and New York: Pergamon Press, 1959–1960.) £48 net complete. (Separate volumes range in price, according to size, from 63*s*. to 100*s*.)

THE First International Congress of Biochemistry was organized on the initiative of the Biochemical Society, and was held in Cambridge eleven years ago. There were about 1,700 members and the main publication, apart from a greatly treasured book on Gowland Hopkins, was a volume of abstracts of communications which would almost fit into the pocket. In 1958, the Fourth International Congress was held in Vienna. More than 5,000 attended and the publications of this Congress, now complete, amount to no less than fifteen substantial volumes—well over 4,000 pages in all. It is astonishing that this large bulk of published material should have emanated from the proceedings of a meeting lasting only six days. It is a reminder of the organizing efficiency and hard work of Prof. Hoffmann-Ostenhof (who has also acted as general editor of these volumes) and his colleagues in Vienna, who made it possible for so many communications to be given in so short a time. This meant, of course, that members frequently had to make a choice from among several communications which were being given simultaneously. Now, with the publication of these volumes, they can read what happened at the meetings they had to miss.

The first twelve volumes are devoted to the symposia. It should be stressed that the pre-prints which were made available at the Congress are no substitute for these volumes, which contain revised and much more complete accounts of the meetings. Moreover, they give some account of the discussion which took place. The subjects covered (with volume numbers and editors in parentheses) are the following: (1) carbohydrate chemistry of substances of biological interest (M. L. Wolfrom); (2) biochemistry of wood (K. Kratzl and G. Billek); (3) biochemistry of the central nervous system (F. Brucke); (4) steroids (E. Mosettig); (5) antibiotics (K. H. Spitzy and R. Brunner); (6) biochemistry of morphogenesis (W. J. Nickerson); (7) biochemistry of viruses (E. Broda and W. Frisch-Niggemeyer); (8) proteins (H. Neurath and H. Tuppy); (9) physical chemistry of high polymers of biological interest (O. Kratky); (10) blood-clotting factors (E. Deutsch); (11) vitamin metabolism (H. Molitor and W. Umbreit); (12) biochemistry of insects (L. Levenbook).

The colloquia, dealing with topical questions in biochemistry, are given in Volume 13. They include: sulphur metabolism (edited by K. S. Dodgson); purine and pyrimidine biosynthesis (edited by H. Chantrenne); oxygenating enzymes (edited by O. Hayaishi); metabolism of C_1-compounds in micro-organisms (edited by Sir Hans Krebs); biosynthetic mechanisms in higher plants (edited by P. K. Stumpf); and growth chemistry of bacteria (edited by G. Toennies and E. E. Snell). Volume 14 (edited by W. Auerswald and O. Hoffmann-Ostenhof) contains the transactions of the plenary sessions and includes the invitation lectures of the Congress. Prof. E. Chargaff, of New York, lectured on the chemistry of heredity, and Prof. E. Braunstein, of Moscow, on the chemical integration of nitrogen metabolism. Volume 15 consists of abstracts of the sectional papers together with a subject index of the symposia and colloquia, ranging from 'abietic acid' to 'zymosterol'.

The printing, illustrations and binding of these volumes are of high quality. Presumably, most biochemists will have to look to their librarians rather than to themselves to provide the complete set, but fortunately, individual volumes can be bought separately. Whether congress publication can go on increasing in bulk at its present rate, or even be maintained at its present level, is another matter. It might be argued that the amount of material and the cost of its publication are becoming unmanageably large and that, in any event, much of the work will be published in more definitive form in the regular journals. However that may be, to those who were there, these volumes will bring back memories of a week of friendly hospitality in beautiful surroundings—memories, not only of scientific discussions, but also of Mozart's 'Magic Flute' at the Vienna State Opera, and of the first sight of Melk Abbey. All biochemists owe a debt to the organizers of this Congress, and to those who worked afterwards to produce this most impressive permanent record of the meeting.

PROGRESS IN ALKALOID CHEMISTRY

The Alkaloids

Chemistry and Physiology. Edited by R. H. F. Manske. Vol. 6 (Supplement to Volumes 1 and 2). Pp. xii+442. 14 dollars. Vol. 7: Supplement to Volumes 2, 3, 4, and 5. Pp. xiii+558. 17 dollars. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.)

THE arrangement of these volumes follows that of the five original volumes of "Manske-Holmes" which appeared during the period 1949–55, and which these are designed to supplement. The relation of their chapters and sections to the chapters of the original work is carefully detailed, and the numbering in the bibliographies continues from the numbers previously reached. The authorities from Canada, Czechoslovakia, Germany, Hungary, Switzerland, the United Kingdom and the United States are those who contributed the chemical sections of the original, and, like the editor, have lost nothing of their clarity and comprehensive grasp.

The bibliographies may generally be taken to cover as far as 1957, with addenda in one or two cases to 1958. The two volumes may therefore be regarded as an exhaustive review of progress during something less than a decade in alkaloid chemistry.

There is no systematic supplementing of the nine chapters in Volume 5, by specialists on particular pharmacological aspects—among which, even a short time ago, 'tranquillizer' effects found no place—but this omission is to some extent made good by summaries of relevant pharmacological work included in many chapters of the supplement. An attractive example may be noted in section 5 of the chapter on tropane alkaloids, tracing the correlation of mydriatic effects with an esterified α-hydroxyl group on C(3) (as in atropine and hyoscyamine), anæsthetic effects with esters of the stereoisomeric

3β-hydroxyl compounds (in cocaine, tropacocaine and psicaine) and central nervous system stimulation with N-substituents, irrespective of the orientation of the 3-hydroxyl group.

In contrast, the other not strictly chemical topic—that of "Alkaloids in the Plant"—has been so amply supplemented as to extend the bibliography references from 175 to 452; and to the more general reader, this could conceivably prove the most rewarding chapter in the two volumes. It is estimated that about 1,000 naturally occurring vegetable alkaloids have now been characterized, occurring in 10-20 per cent of all plants, and at all levels of the vegetable kingdom, including fungi, lichens and fern-allies. Even these figures may prove a substantial under-estimate if smaller amounts of alkaloids are looked for and recorded; and it may well be the case that there is nothing at all exceptional in the capacity to biosynthesize alkaloids, but only in the capacity to tolerate them in substantial quantities. Thus, in an example quoted, the tomato plant, though itself elaborating small amounts of nicotine, succumbs to the effect of a higher concentration when grafted on to *Nicotiana*.

By the use of radioactive tracers, considerable advances have been possible in knowledge of the site and mechanism of alkaloid biosynthesis. Ring-closure of amino-acids emerges as a widespread pattern, though not always by the most obvious sequence: while the pyrrolidine ring in nicotine, for example, is shown to originate from ornithine, radioactive lysine (the next higher homologue) did not contribute as expected to the pyridine ring, and its radioactivity appeared again in the pyrrolidine nucleus.

Work on variations of alkaloid content due to environmental factors, and to minor genetic differences between geographical races, is rather briefly summarized; and no reference is made to the protracted investigation of these factors in the opium poppy, sponsored by the United Nations to assist in tracing the currents of illicit circulation of opium.

Throughout such botanical-chemical studies, the establishment of a chemical basis for taxonomy remains as a shining objective. The wide distribution with which some alkaloids are now to be credited, however, must be a signal for caution in applying chemical criteria except within narrow and regular taxonomic groups.

Of the original 38 chemical chapters, 30 are now supplemented, affording examples both of swift expansion over new fields, and of the final conquest of ancient peaks previously reconnoitred in long and strenuous approaches. In the former category, most space is claimed by the *Rauwolfia*, *Amaryllis*, *Veratrum* and *Senecio* groups. At the date of the original volumes, knowledge of the *Rauwolfia* alkaloids covered only seven bases of unknown constitution, while from the Amaryllidaceae fifteen were known. From the same sources, the present supplement describes more than forty and more than seventy respectively, the greater number of which are elucidated as to structure, and some of which, including reserpine itself, have been synthesized. Such rapid advances have been mainly made possible by the use of chromatographic techniques for the separation of complex mixtures, and of paper chromatography and infra-red spectra as criteria of a complete separation.

In a comparable way, the use of X-ray crystallography for final confirmation of the structural formulæ, deduced from many years of degradative chemical investigation, may be said to have consolidated the jumping-off ground for the long-awaited syntheses of strychnine, morphine and hyoscine. All these are recorded in the present volumes; and surely it would be a sluggish soul that would find anything out of place when they are chronicled, with a touch of unwonted rhetoric, as a storming of citadels. E. G. KELLETT

BRITISH DEER FORESTS

The Deer Stalking Grounds of Great Britain and Ireland

Compiled by G. Kenneth Whitehead. Pp. xviii+556+38 illustrations. (London: Hollis and Carter, Ltd., 1960.) 126*s*. net.

THOUGH the subject has been tackled by three previous writers between 1839 and 1923, this is the first really comprehensive survey of deer forests in the British Isles, and certainly the first with such abundant statistics of the deer bagged. The major part of the book consists of an alphabetical list of deer forests, with the following details: acreage; area above 1,500 ft, and below 1,000 ft., highest and lowest ground; number of deer killed annually, divided into stags and hinds for both pre-1940 and post-war; average weight of stags and hinds, with weight of heaviest stag known to have been killed; and particulars of the most important heads recorded for the forest.

A series of detailed appendixes gives an alphabetical list of the owners of deer forests and shootings in 1959; a counterpart list of the deer forests with their owners; a list of properties of the Forestry Commission in or adjacent to deer-forest country; four different classifications of the best red deer heads recorded in the British Isles during the past 200 years; and a list of the heaviest wild red deer stags known in the same period. The whole is garnished with 38 excellent black-and-white photographs, a dozen useful maps showing the actual location of each forest, a bibliography and several indexes.

It is clear that the sportsman interested in deer-stalking could scarcely expect a more complete provision for his needs. For the naturalist, too, there is an immense amount of valuable material to be quarried from Col. Whitehead's research. Statistical analysis of all these figures about average weights and head sizes surely ought to produce information of much value. There is also a great deal of important information tucked away in the notes that follow the figures about each deer forest, such as when and whence deer have been introduced into them to raise the quality of the native stock, and how these introductions have fared.

Though the great majority of British deer forests are in the Highlands of Scotland, there are also a few in England and Ireland, but none in Wales. The fact that the red deer of Exmoor and the New Forest are hunted with hounds excludes them from consideration, but seven deer forests are listed for the Lake District, while introduced deer have enabled Lundy Island in the Bristol Channel, the Roches in the moorlands of Staffordshire, and Thetford Chase in the Norfolk Breckland to qualify for inclusion. In Ireland there are ten deer forests, mainly in Counties Donegal, Kerry and Wicklow.

One can have no hesitation in affirming that this very thorough piece of work will hold its own as the standard work on British deer forests until the end of the century, and probably well into the next one as well. But I commend to the Deer Group of the Mammal Society of the British Isles the task of making good use of the vast store of natural history information it contains.

R. S. R. FITTER

GEOMORPHOLOGY OF WALES

The Relief and Drainage of Wales

A Study in Geomorphological Development. By Eric H. Brown. Pp. xii+186+24 plates. (Cardiff: University of Wales Press, 1960.) 30*s*.

DURING the course of the past hundred years a considerable diversity of opinion has accumulated concerning the nature, origin and age of the erosion surfaces in Wales. Many of these views are mutually exclusive. Thus the Permo-Triassic age suggested by O. T. Jones conflicts with Jukes Browne's Cretaceous, and both with W. M. Davis's Tertiary. A. C. Ramsay's submarine hypothesis is in contradiction with W. M. Davis's subaerial argument, and so on. Equally complex is the problem of drainage evolution. T. N. George supports the view of rivers extending their courses across emergent wave-cut platforms of Pliocene age, while A. Strahan has proposed that the new discordant rivers of South Wales have been superimposed from a Cretaceous cover.

The problems of the evolution of drainage and the extent, origin and age of the erosion surfaces are closely linked; these together form the basis of the denudation chronology for any given area. For the first time for Wales these two lines of inquiry are brought together in Dr. Eric Brown's study of the relief and drainage of the whole principality. The survey is thus in the tradition of the classic accounts of the French *Plateau Central*, by Henri Baulig, and *Structure, Surface and Drainage in South East England*, by Profs. Wooldridge and Linton.

This new book is the product of many years of study and much field work, and gives for the first time a systematic geomorphological account of much of the landscape of Wales. Although some of the conclusions advanced by Dr. Brown are open to discussion, all those interested will applaud his introductory survey of the relief and structure of Wales and his masterly account of the views put forward during the past hundred years to account for these features.

In the second half of the book Dr. Brown advances his own interpretation of the denudation chronology in considerable detail. Evidence is submitted for the existence of at least three high-level subaerial peneplains of early Tertiary age above 700 ft.: and below this height for a series of coastal plateaux, notably at 600-, 400-, 300- and 200-ft. levels, of submarine origin and Pleistocene age. The drainage evolution is worked out in relation to these erosion surfaces. Forty-seven maps and diagrams and twenty-four plates support the text, and the account concludes with a comprehensive bibliography.

The bibliography will be of great value to future research workers in this field, but it is perhaps unfortunate that there is no reference to Dr. Brown's paper on "The Physique of Wales" given to the Royal Geographical Society on October 29, 1956 (*Geographical Journal*, 123, Part 2, June 1957). This paper is of great interest and value, as the nature and extent of the problems still outstanding after Dr. Brown's analysis and synthesis of the geomorphology of Wales clearly emerge in the discussion which followed. One other addition to the book might have been considered—a short glossary of Welsh landscape terms. So many Welsh place names arise from the topography that additional interest would doubtless be added for the English reader if an indication of the meanings were made available.

W. G. V. BALCHIN

INTRODUCING METEORITICS

Principles of Meteoritics

By E. L. Krinov. Translated from the Russian by Irene Vidziunas. Translation edited by Harrison Brown. (International Series of Monographs on Earth Sciences, Vol. 7.) Pp. xi+535+7 plates. (London and New York: Pergamon Press, 1960.) 70*s*. net.

THE original edition of Krinov's introductory book on the study of meteorites has been available in Western meteorite laboratories for some years, but it is doubtful whether many investigators have actually read more than the sections of particular interest to their own work. It is essentially an introductory text, and, as such, may be read with profit by the sort of informed lay public at which Sir Lazarus Fletcher's British Museum guide was directed; but there is also included a section on the external appearance of fusion crusts which represents an important original contribution to the subject by the author himself. D. R. Chapman's recent article on tektites (*Nature*, 188, 353; 1960) indicates how profitably such work may be extended by aerodynamicists.

The treatment is naturally from a Russian point of view, and most of the specialist articles quoted are of Russian origin, but a real effort was made in the original edition to acknowledge the importance of work by Prior and Hey, Perry, Urey and others. The translated version also includes a selection of both Russian and American work published since the original edition.

In so far as I am able to check it, the translation appears very faithful. In the original, the text and legend are at one in their misinterpretation of Fig. 121, whereas in the translation the text follows the original, but the legend (Fig. 129 of the translation) has been altered to a factually correct form.

Several additional illustrations have been incorporated in the translated edition, and some of the original illustrations have been replaced by more up-to-date or clearer ones. In a work of this nature the half-tone illustrations are of great importance, and it is very unfortunate that in reproduction some of them have deteriorated. On the other hand most, but not all, of the new illustrations are of good quality. A very serious loss in the translated edition is the totally inadequate version of Fig. 52, but this could easily be corrected.

H. J. AXON

Vistas in Free-Radical Chemistry

Edited by Dr. W. A. Waters. (International Series of Monographs on Organic Chemistry, Vol. 1. Supplement No. 3 to *Tetrahedron*). Pp. ix+251. (London and New York: Pergamon Press, 1959.) 75*s*. net.

THIS book is published in memory of Dr. Morris S. Kharasch, and is a fitting tribute to one of the great organic chemists of this century. A complete list of the published papers of Kharasch and his collaborators is given, and is followed by a selection of twelve papers which are presented in full; these include descriptions of Kharasch's early work on the discovery and exploitation of the 'peroxide effect' and some recent work on polymerization reactions. Many of us have a lesson to learn from Kharasch's attention to detail, which has led to several important discoveries. F. R. Mayo and C. Walling pay personal tributes to Kharasch, and give very interesting accounts of their work in collaboration with him. An account of modern work and trends in free-radical reactions in solution is given by W. A. Waters.

The book concludes with chapters on homolytic aliphatic and homolytic aromatic substitution, by H. C. Brown and D. H. Hey, and some other aspects of free-radical chemistry, including a concise account of free-radical reactions in gases by K. O. Kutschke and E. W. R. Steacie. The object of including these chapters is to illustrate the effect of Kharasch's research on the development of free-radical chemistry; this is now such a large subject that a comprehensive treatment would not be possible in only 250 pages. The aspects selected will be, on the whole, of interest to organic chemists, particularly those working on free-radical reactions.

The volume is a useful historic record of Kharasch's contribution to free-radical reactions in solution.

A. B. Callear

Public Relations and Management

By David Finn. (Reinhold Management Science Series.) Pp. xiii+175. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1960.) 36*s*. net.

SUSPICION of those who court publicity has led the British people to look askance at men and women who act as public relations officers for their organizations. This suspicion has been strengthened by some of the public relations practitioners whose efforts to influence the Press have been, to say the least, somewhat unsavoury.

Against this canvas, genuine public relations officers have had difficulty in establishing themselves and, particularly, in showing that their jobs consist of considerably more than preparing hand-outs for the Press. Yet many companies are becoming aware that it is not enough to provide needed goods and services for the community; to obtain maximum results the company must present an image to the public which will persuade more and more people to make use of those goods and services. The public relations officer is concerned to influence public opinion favourably towards his company.

David Finn is an experienced public relations consultant in the United States and, in this book, does much to show the worth of effective public relations to a company. He strips the gloss from the brassy publicity-seeking public relations officer, and illustrates how the practitioner can create a favourable climate of opinion for his company by examining every corporate act to see what effect it will have on public opinion and how projects should be designed to win public support. Besides managing directors, this modest, well-reasoned case should appeal to many heads of institutions outside the world of industry.

T. H. Hawkins

Homotopy Theory

By Sze-Tsen Hu. (Pure and Applied Mathematics, Vol. 8.) Pp. xiii+347. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959.) 11 dollars.

A COMPREHENSIVE introductory account of the rapidly growing field of homotopy theory is welcome; the present volume is rather less concise than Hilton's Cambridge Tract, and differs from it somewhat in content. It is not altogether easy reading, and a really sound knowledge of elementary algebraic topology is an essential preliminary. The main problem in homotopy theory is the extension problem studied in Chapters 1 and 2; fibre spaces and mapping spaces fill Chapter 3. The next four chapters deal mainly with homotopy groups and cohomotopy groups, and the final group of four chapters is concerned chiefly with spectral homology theory. Specialists in a domain which is expanding so quickly may quarrel with some of the omissions; but the young topologist must be grateful for so well-balanced and clear an account. There are exercises to each chapter, but the reader must be warned that these range from the trivial to the impossible, the latter being those which merely summarize results to be found in the periodical literature of the subject; a clear separation between genuine exercises and bibliographical annotations might have been a better plan.

T. A. A. Broadbent

Dictionary of Nutrition and Food Technology

By Dr. Arnold E. Bender. Pp. vii+143. (London: Butterworths Scientific Publications, 1960.) 30*s*.

DR. BENDER'S *Dictionary* sets out to interpret the technical terms used by the many different scientific and practical groups who take part in the expanding knowledge of nutrition. Practical workers in food technology may well be lost in the jargon of the biochemist, while the scientific workers may need definition of technological terms. The dictionary covers the most common biochemical, bacteriological, chemical and technological processes in food science, with brief descriptions also of equipment used in the laboratory and in manufacturing processes.

The sources of information listed in the introduction to the dictionary provide a useful nutrition bibliography, although there are some serious omissions, such as the failure to give full references for the publications of the U.S. National Research Council and the Nutrition Committee of the British Medical Association. Some of the information on special diets is not from the most up-to-date sources and some misleading statements, such as the correlation of glossitis with ariboflavinosis, need to be corrected. The choice of foods for which composition figures are given seems rather arbitrary, and the sources of the food analyses need some further explanation. However, in spite of such flaws, the dictionary is a useful addition to the nutrition bookshelf and should solve many questions of terminology.

A. M. Copping

AUSTRALIAN UNIVERSITIES

By Sir ERIC ASHBY

Clare College, Cambridge ; formerly Professor of Botany, University of Sydney

IN 1957, a Committee appointed by the Prime Minister of Australia, under the chairmanship of Sir Keith Murray (chairman of the University Grants Committee in Great Britain), issued a report which has brightened the prospect for Australian universities. One outcome of the Murray Report was the creation of an Australian Universities Commission, which consists of five members : a full-time chairman (Sir Leslie Martin, formerly professor of physics in the University of Melbourne), two members drawn from academic life, and two from industry.

The Commission has presented its first Report*. This summarizes the development of the universities over the triennium 1958–60 in student-numbers, staff and finance. It then goes on to set out the Commission's recommendations for the triennium 1961–63 ; and it has chapters on halls of residence and on the future of Australian universities.

It is a record of remarkably rapid expansion since the date of the Murray Report, and a prediction of further rapid expansion over the next three years. The following figures (selected from tables in the Report) illustrate the rate of growth of Australian universities :

	1950	1952	1960
Enrolments	—	27,325	53,478
Academic staff (State universities)	—	1,645	2,972
Recurrent income (£1,000)	3,756	—	22.677

The figures for enrolments indicate that nearly 6 per cent of the 17–22-year-old age group are enrolled at universities ; but the figures have to be interpreted with caution, for only 32,349 of the enrolled students (60·5 per cent) are attending universities full time. No fewer than 15,997 students (29·9 per cent) are taking part-time courses and 5,132 students (9·6 per cent) are external. The figure, therefore, which is comparable with those published by the British University Grants Committee is 32,349 full-time students in 1960. Even so, Australia already has a somewhat higher proportion of her young people at universities than Great Britain has.

The figures for numbers of academic staff also have to be interpreted with caution, for it is characteristic of State universities in Australia that great use is made of part-time staff. However, when the figures for enrolments and for academic staff are adjusted to take account of the fact that there are part-timers in both categories, the student-staff ratio comes out at about 14 : 1, compared with an average for British universities of about 9 : 1, and for American universities, colleges and junior colleges of 13 : 1.

The figures for recurrent income reflect first of all Commonwealth participation in university finance (an increase from £0·388 million in 1950 to £7·610 million in 1960), together with substantial increases in grants from State Governments (from £1·616 million in 1950 to £8·727 million in 1960) and in student fees (from £0·697 million in 1950 to £3·039 million in 1960). It is noteworthy that this fee-income is about the same as the income from fees from 63,068 full-time students in eighteen English universities and colleges in 1954–55.

Notwithstanding the recent rapid expansion of Australian universities, the Commission sees no alternative ahead but further rapid expansion. The Report predicts that by 1966 there will be at least 95,000 students enrolled in Australia's ten universities. It is estimated that the University of Sydney alone will have 16,300 students and the University of Queensland 18,000.

The Commission does not disguise the fact that this immense increase in enrolments will precipitate problems both of standards and of staff. Already such data as are available indicate that fewer than half the students at Australian universities graduate in the minimum time. The Commission does not recommend a stiffening of the standards for entrance to universities, nor an increase in maturity of freshmen (which could be secured by raising the age of entry to universities). So as numbers increase the prospect is that student-performance will deteriorate rather than improve.

This possible deterioration might be corrected by a very substantial improvement of the student-staff ratio (though there is no convincing evidence to support this belief). The Commission estimates that 3,613 university teachers, over and above the present numbers (an increase of more than 100 per cent), will be needed by 1966. To recruit academic staff in these numbers is the most perplexing problem facing the universities of Australia.

Comparisons of costs between British and Australian universities are very difficult to make, and the figures given in the Report (£A.448 per student in Australian State universities compared with £A.562 per student in eight 'representative' British universities) should not be compared without qualifications. The case, however, for increased grants to Australian universities needs no such comparison to support it. After surveying the needs of the universities in detail the Commission makes the following recommendations for the triennium 1961–63. The figures are in millions of pounds (Australian).

	Commonwealth share	State share
State universities		
Recurrent (spread over 1961–63)	25·424	47 040
Capital (including building, furnishings and equipment, 1961–63)	15 385	15 385
Total (1961–63)	40 809	62·425
Australian National University		
Recurrent (spread over 1961–63)	9·250	—
Capital (including building, furnishings and equipment, 1961–63)	5 156	—
Total (1961–63)	14 406	—

---

* Report of the Australian Universities Commission on Australian Universities 1958–1963. Pp. vi+77. (Commonwealth Government Printer, Canberra, 1960.)

If these recommendations are accepted the overall expenditure on universities from Government sources (both State and Commonwealth) in the triennium 1961–63 will be nearly £118 million.

In commenting on the prospect which confronts higher education in Australia, the Commission encourages universities to explore fresh ways to make the best use of their available accommodation and high-level man-power. It mentions a submission received from Prof. H. C. Webster in Queensland, outlining a revision of the university calendar which would lead to doubling of utilization of lecture rooms and laboratories, and an experiment already operating in the University of Pittsburgh which allows some students to spend eleven months instead of nine each year on formal academic work. The Commission also suggests that some consideration might be given to the creation of 'satellite' colleges, associated with parent universities, for first-year students. Australia already has experience of this, for the University of Melbourne set up a temporary first-year college near Mildura at the end of the Second World War. It is clear from a reading of the Commission's Report that the Australian universities, which in their constitution and administration are modelled on Scottish universities, have reached a critical stage of their history. Their size has already outgrown their structure. The Commission is evidently giving very careful thought to their future, and is encouraging the universities to propose solutions to the problems which confront them.

PSYCHOLOGY AND THE INDIVIDUAL

By G. W. H. LEYTHAM
Department of Psychology, University of Liverpool

MORE than a hundred years ago, John Stuart Mill differentiated between Psychology, the science of mind, and Ethology, the science of character: "The one ascertains the simple laws of Mind in general, the other traces their operation in complex combinations of circumstances. Ethology stands to Psychology in a relation very similar to that in which the various branches of natural philosophy stand to mechanics. . . . Ethology, the deductive science, is a system of corrolaries from Psychology, the experimental science". ("A System of Logic", 1843.)

The development of psychology has been fraught with dichotomies of this kind, but their proponents have usually been much more partisan than was Mill, and they have been more inclined to regard the two views as being in conflict rather than as complementary. While the academic Wundt was founding the first psychological laboratory at Leipzig in 1879, for the study of the generalized, adult, human mind, Charcot, the medical therapist, was busy in Paris studying the effects of hypnosis on mental patients. The former led to experimental psychology and schools, such as Structuralism, Gestalt and Behaviourism, while the latter paved the way for Freud's psychoanalysis and the divergent theories of Jung and Adler.

Already, in 1894, the German philosopher Dilthey was objecting to the narrowness of experimental psychology, with its explanation and analysis (*Erklärende Psychologie*) and its use of the techniques of natural science (*Naturwissenschaft*). He wanted psychology to study character or human values and to be concerned with understanding and description (*Verstehende Psychologie*). The individual was to occupy a central place in this approach, and psychology would thus serve as a basis for the cultural and social sciences (*Geisteswissenschaft*). In the same year, another philosopher, Windelband, characterized the two approaches as the 'nomothetic' and 'idiographic' respectively. He also felt that the latter was truly scientific, and should be the method followed by psychology.

This distinction between the search for general laws and a concern for the uniqueness of the individual has since shown itself in the gulf which has at times separated the experimentalist from the clinician, the psychologist from the psychiatrist, and, in a wider sense, the pure or theoretical scientist from the applied or practical scientist. It can even be seen in the gap between the sciences and the arts, but in none of these is it necessary or desirable: the aims of the two approaches are different but not antagonistic. Mill said that: "Art in general, consists of the truths of Science, arranged in the most convenient order for practice, instead of the order which is most convenient for thought," and according to his definition, ethology was "the science which corresponds to the art of education; in the widest sense of the term, including the formation of national character as well as individual".

In his presidential address to the British Psychological Society in 1958, Rodger spoke about "Psychologists: Non-medical and Medical"[1], and discerned at least three dichotomies in the history of psychology: cognitive versus non-cognitive (what is studied); experimental versus non-experimental (how it is studied); and laboratory versus extra-laboratory (where it is studied). He pointed out that those working in one 'cube', for example, carrying out experiments in the laboratory on cognitive processes, should realize that theirs was only one room in a large house, and that they should not ignore or belittle the work going on in the other and more distant ones, for example, observations of neurotic behaviour made in the clinic.

The conciliatory nature of Rodger's address may well be taken as a sign of the times, for there are encouraging indications that as psychology emerges from its reviewing phase, it is inclining away from the old theses and antitheses towards a new synthesis. Take, for example, the series of papers on modern trends in psychology[2] read at the annual conference of the British Psychological Society in 1960. The first was concerned with "perception and information theory" and indicated some of the ways in which the mathematical theory of communication deriving from Shannon and Weaver (1949) could be applied to perceptual data. In this approach, the limitations of which are noted, the stimuli are regarded as 'input', the subject as a 'communication channel', and responses as 'output'. The paper on behaviour theory pointed out that the large-scale, controversial theories, such as those of Tolman and Hull, were going out of fashion and were being replaced by an emphasis on fact finding and the construction of mathematical models based on a probabilistic conception of behavioural processes. Models using concepts from electronics or communication engineering, and having an obvious connexion with cybernetics (Wiener, 1947), were also being used. The contribution on social psychology welcomed the rapidly diminishing use of stimulus-response language in that field, and noted an increased stress on human interaction and language. One systematic approach to the former owed much to the theory of games, while the latter could be studied in terms of information theory, or as an important aspect of the sorts of constructs a person builds up to make his world more predictable, and to use in identifying and evaluating his social environment.

In the remaining paper, on thinking, Allport is quoted as saying that our entire mental life is dominated by a process whereby experiences are formed into clusters, concepts, or categories. While this interest in concept formation and language obviously relates the psychology of thinking to social psychology, one can also see affinities with the other two fields already mentioned: current research in thinking is largely exploratory, and some of it stems from analogies drawn between thinking and information-processing computers. The use of probabilistic inference in the solving of syllogisms has also been investigated. The kind of strategy a person will use to solve a problem seems to depend largely on his previous experience; hence there is also a connexion with personality studies and with a consideration of the individual.

Perhaps this fresh impetus in the long-neglected study of human thinking and language will hasten the reconciliation of the nomothetic and idiographic approaches and bring us nearer to the day when the truly complementary nature of Mill's two sciences will be realized. This would also seem to be the opinion of Hearnshaw who, in his presidential address to the British Psychological Society in 1956[3], spoke of the tension "between the demands of scientific method and the appreciation of the richness of human individuality". He said: "I can see only one way of narrowing the gap between the scientific and humanistic psychologies, and that is through a gradual encroachment of scientific techniques upon territory already roughly mapped by humanistic insight. This means in effect a constant search for concepts which, while capable of scientific definition and employment, nevertheless possess humanistic implications in the sense that they throw light upon peculiar, or, as they are sometimes termed, the higher attributes of men". His own interest in the psychology of thinking has centred around temporal integration, which he regards as one such bridging concept.

Allport, in his book "Becoming" (1955), considered that: "Virtually all modern psychological theories seem oriented toward one of two polar conceptions . . . the Lockean and the Leibnitzian traditions respectively". Whether this be regarded as a dichotomy or a continuum, it can be seen to be very much in line with the scientific–humanistic conflict inherent in the other pairs of opposites. At the Lockean end, man is a *tabula rasa* reacting to external forces, while at the Leibnitzian end, he is the monadic source of all his behaviour. Put in these extreme forms, the inadequacy of either taken by itself becomes obvious, and one can see that although some theories in psychology are presented as if they accounted for the whole of man's behaviour, they do in fact only refer to part of it. Many theories are thus mutually exclusive rather than contradictory, and complementary rather than in conflict. Allport felt, however, that psychologists had tended to concentrate too much on the lower end of the scale, and he called for further scientific studies of the later and higher levels of development, including growth, adulthood, and man's religious sentiment. Such investigations would serve to augment many already carried out on rats, children and neurotics, and as he saw it: "The major task of psychology to-day is to enlarge its horizons without sacrificing its gains".

Several straws in the wind suggest that Allport's dictum is being taken seriously, for apart from the renewed interest in the psychology of thinking mentioned above, the study of mature people made by Maslow, and reported in his book, "Motivation and Personality" (1954), has opened up a new field of inquiry, and the numbers interested in psychological health and the potential greatness of man has grown so rapidly that a new periodical, *The Journal of Humanistic Psychology*, is to start publication very shortly. The new American *Journal of Existential Psychiatry* also provides a forum for those who wish to "help shape the picture of an organism at once mechanical and random, statistical and individual, limited and free", and is evidence of the increasing rapprochment between the humanized behaviourism of the United States and the Continental stress on man-in-action and phenomenology.

The recent "Handbook of Aging and the Individual" (1959), edited by J. E. Birren, reveals a growing interest in adulthood and old age, and the study of human phenomena not at the moment susceptible to high levels of numerical description has been greatly facilitated by the appearance of Siegel's "Non-parametric Statistics for the Behavioral Sciences" (1956).

A pioneering study by Harlow on "The Nature of Love"[4] has shown how problems of the clinic and everyday life can be investigated experimentally in the laboratory, and serves to emphasize that techniques are of secondary importance. Provided he asks worthwhile questions, the psychologist has no need to apologize because his laboratory does not resemble a real-life situation. A vacuum is scarcely representative of the physical world, yet Lord Kelvin once said that we knew more about a vacuum than we knew about anything else. As, in going from a vacuum to the everyday physical world, allowance must be made for the properties of the particular object and the forces acting on it, so, in going from the laboratory to the everyday psychological world, we must allow for the heredity and experiences of the particular individual and the psychological forces present in his environment. Presumably this is what Mill meant when he said that psychology was the science of the elementary laws of the mind and ethology "the subordinate science which determines the kind of character produced, in conformity to those general laws, by any set of circumstances, physical and moral".

Einstein said: "The object of all science, whether natural science or psychology, is to coordinate our experiences and to bring them into a logical system". ("The Meaning of Relativity", p. 1.) The experiences of psychologists have been so diverse that one would expect their logical systems to be varied too. Observations of the behaviour of rats running in mazes may well lead to a theory quite different from one based on listening to the free-associations of neurotics lying on couches. These are complementary theories, however, and not alternatives: each is limited and applies to a different situation.

The big need in psychology to-day is for a conceptual framework in which all the experiences and theories can be related to each other. We have theories for many of the bits, but so far there is no satisfactory theory of the whole. Such a theory would not only have to bring together and relate the various aspects of behaviour, but would also have to take account of the fact that development and growth are psychological as well as biological.

As a first step in this direction, it would be helpful to have an agreed unit for the science of psychology. The most obvious and useful one is that of the individual, but although lip-service is often paid to this it is frequently reduced to a physiological organism or an inanimate machine, and is rarely described in psychological terms derived from a consideration of the integral and extensive nature of its behaviour. In an attempt to establish the individual as the unit of psychology, I would like to introduce a model of it which I have been developing over the past few years, and which I have found helpful as an integrating framework.

A diagram of the structure of the individual is given in Fig. 1, and although a detailed description of its dynamics is not possible here, it is hoped that the following summary will give some idea of its possibilities in expediting the above-mentioned trends towards the extension and unification of psychology.

Introductory text-books in psychology seem to have grown by accretion rather than by design, and there is a certain autonomy about their chapters which makes it difficult to appreciate the essential unity of the individual's behaviour. How would the proposed model cover the topics of the various chapters and help to bring them together into a unified whole?

The social, physical and biological environments impinge on the individual at the nucleus, which is both a transformer and a relay station: it transforms incoming stimuli and relays them to the ego and also receives outgoing stimuli from the ego and transforms them into action or responses. Psychologists studying the relationship between the behaviour of the psychological individual and the activities of the biological organism, or with the machine-like aspects of behaviour, would be concerned mainly with the properties and functions of the nucleus. Those interested in problems of sensation would find the physical level of awareness and its relation to the nucleus relevant to their work. Feeling and emotion would, of course, have special reference to the emotional level of awareness, while reasoning and other activities involving the use of language would come within the sphere of the mental level of awareness. Certain aspects of creative thinking and the higher forms of religious experience would be referred to the intuitive level of awareness.

The ego can operate on any level of awareness and represents immediate experience or the perceptual world, from which the social, physical and biological worlds are inferred. Problems of perception would thus relate to the dynamics of the ego and the particular level of awareness on which it was functioning. Learning would also apply to all levels, and it seems likely that psychological time (the 'specious present') would correspond with increasing spans of physical time at successive levels of awareness away from the nucleus.

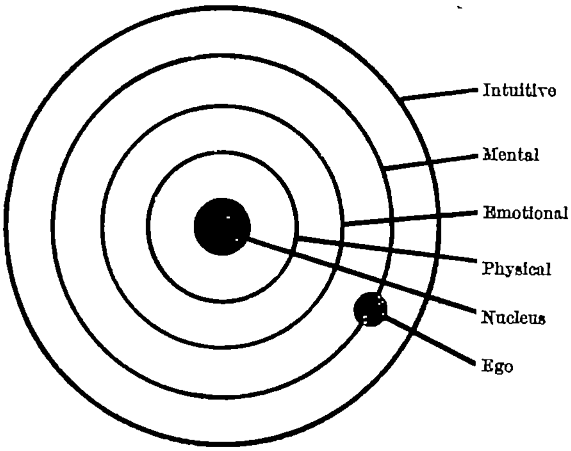

Fig. 1 A model of the individual, showing the four levels of awareness, the fixed nucleus, and the mobile ego

The successive levels of awareness are also related to the successive stages in psychological development, and these may be understood with reference to the range and preferred focus of ego functioning. The model accords well with Maslow's theory of motivation, which states that "the basic human needs are organized into a hierarchy of relative prepotency". As a 'lower' need becomes satisfied, or assured of satisfaction, so the next 'higher' need emerges and becomes central in guiding behaviour. Maslow's hierarchy of needs, together with the aspect of the model of the individual to which they seem relevant, are as follows: physiological needs (nucleus); safety needs (physical level of awareness); belongingness and love needs (emotional level of awareness); the esteem needs (mental level of awareness); and the need for self-actualization (intuitive level of awareness).

It will be seen that Jung's four functions—sensation, feeling, thinking and intuition—also bear a close resemblance to the four levels of awareness. So far as possible, static terms such as 'the unconscious' would be avoided in this model and would be replaced by dynamic relationships, for example, relative availability to the ego as determined by comparative thresholds of arousal.

As we come to know more about the unity of the individual and the way in which its different parts are integrated to function harmoniously, so may we come to understand not only optimal psychological growth, but also disintegration and disharmony. A useful model would thus help us to ask the right questions and guide our search for fresh facts, as well as enhancing the value of the facts already known by bringing them together and relating them in a dynamic system.

How would the suggested model help to bridge the gap between the pure and applied fields of psychology? The structure and dynamics of the abstract, theoretical individual, would be the concern of the pure scientists, while the application of the generalities thus found to the life and experiences of the particular individual in his particular situation would constitute the aims of the applied psychologists. Knowledge obtained in this latter field would be 'fed back' to the theorists and experimentalists to help them in the modification of their model and in the formulation of vital problems for research. The two aspects of psychology would thus be complementary and mutually helpful, and the answer to the question implied in the title of Lafitte's book, "The Person in Psychology: Reality or Abstraction" (1957), would be 'both': reality in applied psychology, and abstraction in pure or theoretical psychology.

I have tried to show that the time now seems ripe for an attempt to integrate and unify the many facets of psychology, and have proposed a model of the individual as a contribution towards this. Should it prove helpful to psychologists as a logical system whereby they can co-ordinate their experiences, then the similarity between its structure and those of the atom and the solar system may also take us a step nearer to that more distant goal of the unification of all science.

THE COSMIC RAY FLARE ON NOVEMBER 12, 1960, AND SOLAR ACTIVITY DURING THE PERIOD NOVEMBER 10–15, 1960

By STAFF OF THE IONOSPHERE AND RADIO-ASTRONOMY SECTION OF THE NETHERLANDS POSTAL AND TELECOMMUNICATIONS SERVICES

THE region of solar activity which passed the central meridian on November 12, 1960, at heliographic latitude 27° N. produced a remarkable series of flares, two of which caused cosmic-ray effects at ground-level. In this communication we give a short account of the optical, radio-astronomical, cosmic-ray and earth-current observations made at the Nera Observatory of the Netherlands Postal and Telecommunications Services and at the observing stations at Paramaribo (Surinam) and Hollandia (New Guinea).

The principal flare events belonging to this series are summarized in Table 1.

The radio responses associated with these flares were all spectral type IV, consisting of prolonged continuum radiation on both centimetre and metre wave-lengths. The durations listed for 200 Mc./s. in Table 1 apply to the main part of the events only. After the flare of November 10, radio noise at this frequency continued to be enhanced up to the early hours of November 13. Initially this enhanced radiation showed relatively little variability, but on November 12 strong activity of type I storm-bursts developed. The flares of November 14 and 15, on the other hand, did not provoke prolonged enhanced or storm radiation.

The flare of November 12 is comparable in importance to that of the famous cosmic ray flare of February 23, 1956. Some of the features of this event will be described here.

Optical Development

Fig. 1 shows some photographs in H_α light of this flare taken at Nera. Notable features of this phenomenon are the following: (1) the undulatory structure of the north-eastern branch (the upper branch in Fig. 1) which was especially pronounced at about 1328 U.T.; (2) the very bright portions between the two big spots and the conspicuous bright knot on the northern side; (3) the very rapid extension of the flare in the south-westerly direction between 13h. 27·5m. and 13h. 28·5m.; (4) the coverage of the nearby spots by luminous material around 1334 U.T.

Table 1. IMPORTANT FLARE EVENTS BELONGING TO THE ACTIVITY REGION WITH CMP ON NOVEMBER 12, 1960
(9,400 Mc./s. data taken from Japanese Ursigram information)

Date	Optical flare		Radio response				Geomagnetic activity
	Position	Importance	Frequency (Mc./s.)	Start time (U.T.)	Duration (min.)	Integrated flux density (10^{-19} × W.m^{-2} (c./s.)$^{-1}$ min.)	
November 10	28° E 29° N.	3	2,980 545 200	1119 1116 1116	33 28 44	1,200 4 500	
„ 11	— —	—	9,400 545 200	0311 0318 0321	104 160 250	— 320 700	
„ 12	2° W. 27° N.	3 + (C.R.)	2,980 545 200	1322 1327 1327	100 100 270	34,000 100? 80	SSC 1348 U.T. (storm : 1710 →)
„ 13							„ 1022
„ 14	20° W. 28° N.	2 +	9,400 545 200	0330 0335 0319	— 120 140	— 12 15	
„ 15	32° W. 30° N.	3 + (C.R.)	9,400 545 200	0217 0221 0221	41 160 238	— 10 40	SSC 1303 storm 2202 →

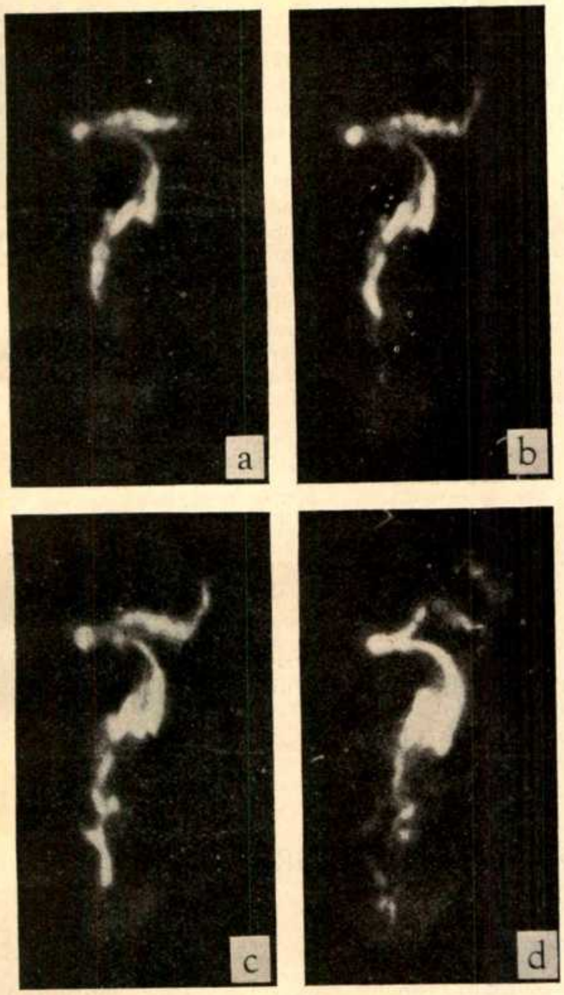

Fig. 1. Photograph in H_α radiation of the flare of November 12. (*a*) 13h. 27m. U.T.; (*b*) 13h. 27·5m. U.T.; (*c*) 13h. 28·5m. U.T.; (*d*) 13h. 34m. U.T.

The overall structure of this flare was very much the same as the structure of a flare earlier in the day, observed at 1012 U.T. at the same position. These two flares illustrate nicely the well-known fact that flares within the same region of activity tend to recur along similar structural patterns.

Radio Responses

A small initial rise at frequencies 9,100 and 2,980 Mc./s. began at 1322 U.T. The onset of the main steep rise occurred at 1324. At frequencies 545 and 200 Mc./s. the onset occurred definitely later, at 1326·5 and 1327·5, respectively. The intensity curve of the unusually strong outburst at 2,980 Mc./s. is reproduced in Fig. 2.

The polarization behaviour at 200 Mc./s. was as follows. During the first 3·5 min., from 1327·5 to 1331, the Nera polarimeter indicated very irregular polarization, fluctuating between right-handed and left-handed. The degree of polarization is unknown, because the total radiation recorder was at first largely off-scale; but it was certainly very small. The irregular polarization behaviour suddenly came to an end at 1331. Perhaps this marks the end of a 'first part' event, which may have been a type II outburst. From 1331 on, the radiation showed about 35 per cent uniformly right-hand polarization. This sense of polarization, which was prevalent throughout the period under discussion, is opposite to the left-handed sense normally associated with sources on the northern hemisphere during the present sunspot cycle.

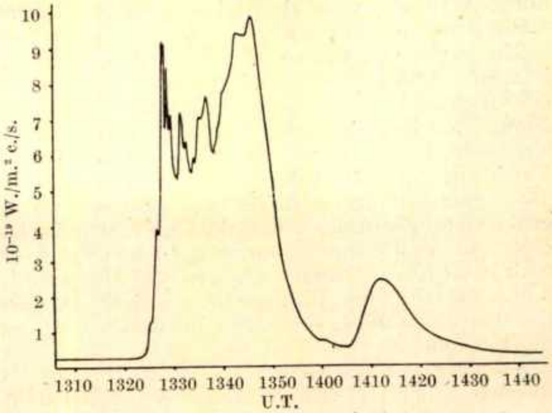

Fig. 2. The outburst at 2,980 Mc./s. on November 12

Cosmic Rays

Observations of the low-energy part of the cosmic radiation are obtained at Nera with a standard duplex neutron monitor. At about 1400 U.T. on November 12 the intensity increased, to reach a first maximum of 13 per cent above the initial level at about 1500. A second increase started at about 1745, to reach a maximum of 56 per cent at about 1930 (Fig. 3). This rise was approximately coincident with a strong increase of geomagnetic activity at

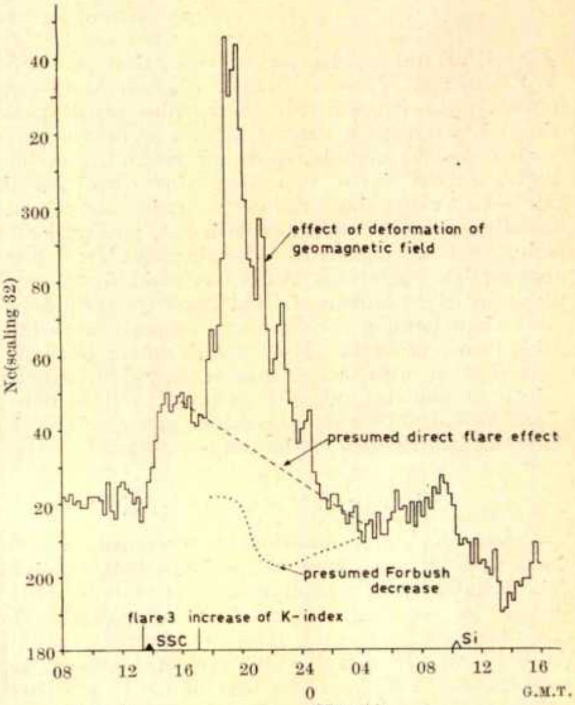

Fig. 3. Cosmic-ray flare effect observed with standard duplex neutron monitor at Nera. The diagram represents 15-min. values, corrected for air pressure

about 1710, following the sudden storm commencement (SSC) at 1348.

The increase of cosmic-ray intensity at about 1745 is most probably due to a lowering of the Störmer cut-off energy valid for the geomagnetic latitude of Nera (53·9°). This lowering of cut-off energy is obviously a consequence of the deformation of the Earth's magnetic field during the violent stage of the geomagnetic storm. Increases in cosmic rays at geomagnetic latitudes lower than normal have been recorded several times during geomagnetic storms with balloon equipment[1]. The event of November 12 represents the first instance in which it has been possible to establish this effect by means of ground observations.

At lower latitudes a Forbush decrease was observed towards 22h. U.T. This decrease is masked in our observations by the cosmic-ray flare effect, except perhaps for the later stage of its recovery (see Fig. 3).

The cosmic-ray increase on November 15 amounted to 15 per cent. The effect had a very regular course and lasted 10 hr.

Earth Current Observations

The cosmic-ray flares of November 12 and 15 were also distinctive in producing exceptionally large solar-flare effects ('crochets') in earth potential measurements at the equatorial stations Paramaribo and Hollandia, respectively.

In the period under discussion, there were two sudden storm commencements. In Table 1 we indicate the flares that can be held responsible for these SSC's. The two flares of November 12 and 15 did not cause an SSC proper, probably because their contribution to geomagnetic activity was superimposed upon already existing disturbed conditions. However, their influence can be traced tentatively in the following way: (1) on November 13 at 1022, 21 hr. after the November 12 flare, a sudden impulse of world-wide character occurred, followed by strongly reinforced geomagnetic activity lasting for several hours; (2) on November 15 at 2202, almost 20 hr. after the November 15 flare, there occurred a world-wide reinforcement of geomagnetic activity, lasting for several hours.

We note the remarkable parallelism in the sequences of events which results from these two suggested connexions:

Flare	Geomagnetic event	Interval (hr.)
November 11, 0311	SSC, November 12, 1348	34·6
November 12, 1322	*s.i.* + increased storminess, November 13, 1022	21·0
November 14, 0336	SSC, November 15, 1303	33·5
November 15, 0217	Increase of storminess, November 15, 2202	19·8

These two sequences were separated by a period of relative quietness setting in on November 14 at about 0200 U.T.

THE EYE, THE BRAIN AND LAND'S TWO-COLOUR PROJECTIONS

By Dr. W. A. H. RUSHTON, F.R.S.
Physiological Laboratory, Cambridge

GREAT interest has arisen from the spectacular demonstrations of Land[1] wherein the superposed projections of two black-white pictures, one through a red glass, can result in a scene filled with varied colours, including good greens and even some blues. Many have said that this disproves the 'classical' view that vision is trichromatic, since Land's colours are obtained with only two projection lights and are named as belonging to almost every region of the spectrum. A few have said (for example, the scholarly comment of Judd[2]) that the results show little that should surprise anyone properly acquainted with previous work. However this may be, it is a fact that in ordinary circumstances red mixed with white is called 'pink' (desaturated red); but in Land's conditions it may be called 'green'. What has happened to the eye or the brain?

Additivity in Monocular Matches

Colour-naming is notoriously unquantitative and hard to analyse, so here we rely on colour matching. The Land projection equipment was built by Dr. A. Karp[3] in the Cambridge University Engineering Laboratories, and lent to me by courtesy of Prof. Hawthorne. Red and white projection lights were superposed, each variable in intensity by partly crossed 'Polaroids'. The picture was a square subdivided into 25 small squares each uniform but differing in the red/white ratio from its neighbours in haphazard fashion. Each small square subtended 1° at the eye and the appearance gave a patchwork in many colours from red to bluish.

Interposed between the observer and the picture was a small white card about one-third the area of a small square. It did not receive any light from the projectors, but was illuminated by a variable mixture of monochromatic lights, red (650 mμ), green (530 mμ) and blue (460 mμ), from a Stiles double monochromator[4], the energies of each component R, G, B being measured by interposing an E.M.I. photomultiplier tube.

Experiment 1. By suitably adjusting the RGB mixture, the card could be made indistinguishable from the small square on which it appeared to lie; for example, seen against a green square the card could be made an identical green. The red projector light was then extinguished, so the card was seen against a grey square surrounded by other greys. The card now appeared bright *pink* though the spectral lights on it had remained untouched. This was to be expected, for initially the card matched the square, so when the red component was removed from the square it should be seen in excess on the card. This expectation proves exact, for if the RGB energies on the card are measured when matched with the square illuminated by: (*a*) the white projection only; (*b*) the red only; (*c*) both together, it is found for each of R, G and B that the energies in (*c*) are the sum of those in (*a*) and (*b*).

It is a well-known feature of the Land picture that its general appearance is little affected by the relative intensity of the two projection lights. Though the 'warmth' of the picture is altered, the red square and the green square are still so named after the ratio of the projection lights has been greatly changed. What happens in these circumstances to the *RGB* proportions on the matched comparison card ?

Experiment 2. The card was placed in front of a green square and matched, the red and the white energies falling on the *square* being measured by interposition of a photomultiplier tube. Now the projection image was shifted across the screen so that, for example, a red square lay behind the card. The two projection intensities were altered so that the energies received on this (still red) square were the same as they had been on the former green one. The unchanged light falling on the interposed card matched perfectly this new square, but now it looked red, not green. Every square with red-white energies adjusted to these fixed values was matched by the fixed card which assumed the colour of each square in turn when viewed in that particular location in the picture.

Conclusion from Monocular Matches

The results are simple and 'classical', being in accord with the law which Grassmann[5] enunciated more than a century ago, namely, that two lights which appear identical in one situation appear so in all. The *RGB* mixture required to match any square is simply the sum of the energies required to match the white component and the red component falling separately on that square. The match is therefore dichromatic, and the projection of two lights, so far from exhibiting 'every colour', leaves enormously more colours unrepresented than those capable of being displayed. This may readily be seen by making a perfect *RGB* match for any Land projection and then altering any one of the *RGB* components to any extent. Every one of the colours so formed is neither produced nor producible by the Land projections employed whatever their ratio or intensity. If we believe that there are three cone pigments in the human eye, all the foregoing matching results may be shown to follow as an inescapable logical consequence.

A fine painting may evoke so realistic an appearance of depth that it is hard to believe that all we see is a flat sheet. There is a sense, then, in which we may say that three dimensions have been represented by only two, but the sense is artistic rather than scientific. It is in a similar sense that we may say that Land's art has evoked the three dimensions of colour.

Complexities in Binocular Matches

We have seen with monocular matches that when considerations are restricted to judgments of identity or non-identity, the relations are precisely of the kind that would be found if the eye were replaced by three photocells each with different spectral sensitivity. So much is entirely expected ; what is surprising is our sensation, for example, that a fixed light looks now red, now green. What is bewitched by Land's magic lantern ? Is it the eye—or is it the brain ? Perhaps when a red light appears green the eye is still sending the normal 'red signal' up the optic nerve, but the brain, confused by messages from the retinal surround, decodes the signal incorrectly. This suggestion can be shown to be wrong. For if it were right a similar normal 'red signal' coming to the brain from the other eye would also be decoded incorrectly in precisely the same way, and hence look the same. (For simplicity of treatment the 'brain' is here considered as a single decoding device operating equally on the messages from each optic nerve and delivering a decoded output which stands in one-to-one relation with visual sensation.)

Experiment 3. One may look with the left eye at the green square in the Land projection, and with the right eye down a tube observing nothing but a card illuminated by the *RGB* mixture from the monochromator. If the mixture on the card matches the green square by monocular superposition it is generally found not to match at all viewed binocularly : the square looks green, the card looks pink, so the left eye cannot be transmitting a normal red signal.

The signal which is being transmitted will be the same as that in the right eye when a binocular match has been established. But Land's colours in general cannot be matched by any spectral mixture seen in the other eye. The browns, olives and greys have too much black in them. This difficulty was overcome by surrounding the card presented to the right eye by a white background of about the colour and intensity of the white Land projection alone.

Experiment 4. These matches were not very easy to make but were reasonably repeatable, and the *RGB* mixture when later observed alone corresponded roughly with the remembered appearance of the particular square matched, so the green-appearing square was matched by a green part of the spectrum (blackened by contrast to the white surround). The particular spectral wave-length corresponding to the *RGB* mixture could be found from the colour triangle of Wright[6] whose primary wave-lengths we have adopted.

Experiment 2 was repeated but with binocular matches made against various squares, each adjusted to receive a fixed energy from the white and from the red projector. The results were quite different from those of Experiment 2, where the match was monocular. Each square now needed a different *RGB* mixture and the (darkened) spectral colour resulting corresponded fairly well to the coloured appearance of each square as seen in normal viewing.

When a binocular match has been established it is plausible (though not certain) that the signals in the two optic nerves are the same. Therefore the binocular match will measure that part of the 'Land effect' which is due to unusual encoding by the eye. It cannot give information about that part which is due to unusual decoding by the brain, since this will be the same for both nerves. That abnormal decoding may be involved, however, is seen from the following experiment.

Experiment 5. A narrow tube is pointed at the Land figure so that on looking through the tube all that is seen is part of one square. First the whole picture is viewed and that particular square noted ; then on looking through the tube its colour is seen unaltered, nor is any change seen on continued observation.

Here is a paradox, for when this experiment is repeated with various squares, each adjusted to receive the same red and white projection energies as in Experiment 2, we have the extraordinary situation in which the eye looks through the tube at an isolated and identical red-white mixture and sees this as a colour which persists (though with dwindling conviction) with a hue which may vary greatly depending upon the past history. It will in fact be the colour of the square as seen previously in the full picture. Though this colour persists—or rather is not seen to change so long as one looks down the tube at the unchanging square, it alters instantly on glancing at a new surround and back down the tube. This persistent memory and sudden change of judgment suggest activity of brain, not eye, and binocular comparison confirms it.

Experiment 6. A binocular match was made as in Experiment 4, and suddenly the surround to the small square was removed by interposition of the tube at the left eye. The binocular match was immediately upset and for restoration needed an *RGB* mixture close to the proportions for the monocular match, though the white surround to the comparison field made a perfect match unobtainable.

This experiment shows that when the surround field is abolished in the left eye the encoded message (as judged by the colour match in the right eye) changes at once to the normal 'pink message'. But it is not seen to change if viewed without binocular comparison. The decoding mechanism in the brain, therefore, either is insensitive to this change of message or it deliberately compensates for it. The first possibility is excluded by the fact that a much smaller alteration in nerve message produced by slightly changing the red/white ratio of the projection lights is easily detected.

We thus arrive at the surprising conclusion (though familiar to psychologists as an example of 'colour constancy') that when the same square is observed through the tube and in the open, the brain in some way recognizes the identity and in its decoding exactly compensates for the change in the message which it receives : and, indeed, when a green square is matched binocularly and then has its surround abolished, the sensation experienced is not that the square goes pink, but that the comparison card suddenly gets more green—at least if one's attention is fixed primarily upon the square. But I am trying to avoid speaking of my sensations !

Conclusions

This article reaches some over-simplified and rather obvious conclusions about the difficult subject of colour appearance.

(*a*) It is easier to analyse by colour matching than by colour naming.

(*b*) Monocular matches are simply the sum of the matches made with each component of projection alone. They follow Grassmann's law and the logic of three cone pigments.

(*c*) Colour appearance may depend on the surrounding field and its past history. These alter the encoding of nerve messages by the eye, and decoding by the brain.

(*d*) The extent of the former may be measured by binocular matches, the extent of the latter by memory matches.

(*e*) The eye–brain model postulated is crude, but it reveals some of the complexity which underlies the sensation of colour.

OBITUARIES

Prof. P. G. H. Boswell, O.B.E., F.R.S.

FEW geologists have accomplished more in the face of chronic ill-health than P. G. H. Boswell, emeritus professor of geology of the Imperial College of Science and Technology, London, who died on December 22, 1960, at Ruthin, North Wales, at the age of seventy-four. Not only did he contribute close on 150 publications, including several memoirs and books, but also he was for long vigorously engaged in teaching and administration at the Universities of Liverpool and London, in the conduct of learned societies, and in proffering geological advice to various industrial and public undertakings.

Born at Woodbridge, Suffolk, in 1886, he developed during adolescence such an absorbing interest in the geology of his native county that in 1912 he abandoned teaching in an elementary school so as to concentrate on geology by studying under W. W. Watts at the Imperial College. While there he continued his researches on the Pliocene–Pleistocene succession in East Anglia and helped to correlate Early human phases with those of the Glacial Period, besides devoting much attention to the Chalk and to an assessment of the magnitude of the Eocene unconformity in the London Basin.

It was while investigating the Tertiary rocks that his thoughts turned to the possibility of using their detrital mineral assemblages for correlating particular horizons. This led him to specialize in the quantitative and qualitative aspects of sedimentary petrology which were to prove so helpful in deciphering the palæogeography, tectonics and climatic conditions of past epochs, and so valuable in connexion with the search for glass-making, moulding and refractory sands during and after the First World War. Shortly after his appointment to the chair of geology at Liverpool in 1917, Boswell started his protracted researches, lasting more than twenty-five years, into the stratigraphy and tectonics of the Silurian rocks of the Denbighshire Moors. Even though some of his structural interpretations have been assailed, there is no doubt that most of his observations, gathered together in a volume on the *Middle Silurian Rocks of North Wales* (1949), will stand the test of time. Always actively interested in the applications of geology to civil engineering, his advice during the planning and construction of the Mersey road tunnel contributed in no small measure to the success of that major project.

In 1930 he was invited to succeed Watts as professor of geology at the Imperial College, but his tenure of the chair was comparatively brief, for he was compelled to resign eight years later because of ill-health. Nevertheless, he continued his work in North Wales and his consulting practice until 1953 ; thereafter, though gravely incapacitated, he still wrote a number of papers on thixotropy, greywackes and allied subjects, ending with a treatise on muddy sediments, to be published posthumously.

Boswell had been president of the Geological Societies of Liverpool (1921–23) and of London

(1940–41), of the Prehistoric Society (1936), and was successively general secretary (1931–35) and general treasurer (1935–43) of the British Association, besides being president of Section C (Geology) in 1932. Other honours included the Bigsby Medal of the Geological Society of London (1928), election to the Royal Society (1931), and honorary membership of many scientific societies at home and abroad; he was made O.B.E. in 1918. He will be remembered with affection and esteem by all his former colleagues and by generations of students, not least by those he inspired at Liverpool during the hey-day of his career.

DAVID WILLIAMS

Prof. E. T. Bell

E. T. BELL, who died in 1960, was born at Aberdeen in 1883. His schooldays were spent in Great Britain, but he attended university in the United States, where he spent the whole of his adult life. He occupied a number of university posts, culminating in his tenure of the chair of mathematics at the California Institute of Technology, Pasadena, 1927–53.

As a schoolboy, Bell came under a mathematical teacher of rare distinction, E. M. Langley, of Bedford, and on Langley's death wrote with warm appreciation of being shown something of the mode and content of modern mathematics by an inspiring teacher, and in particular of being introduced at school to the theory of numbers and to elliptic functions. His research work was mainly in these fields, and he made significant contributions to the classical theory of numbers, the field of rational arithmetic and of Diophantine analysis.

Bell's name, however, was well known outside the restricted circle of professional mathematicians, by the series of books, from about 1930 onwards, in which he endeavoured, with substantial success, to explain modern mathematics to the intelligent layman. Of these books, three deserve special mention. In *Mathematics, Queen and Servant of Science* (1952), a conflation of two earlier volumes, he described the dual nature of mathematics, its remoteness from prevalent crude materialism and its extraordinary knack of becoming vitally relevant to material concerns. If there are two cultures, mathematics, belonging to both, is the essential bridge between them. *Men of Mathematics* (1937) relates the outstanding mathematical discoveries of the ages to the men who made them; sufficient personal detail is given to allow the reader to see mathematicians as human beings, but emphasis throughout is on their contributions to mathematics. Something of the same theme runs through *The Development of Mathematics* (1940), which is not an encyclopædic history of the subject, but a narrative of carefully chosen main trends, themselves presented through typical major episodes; it is a graphic map of the main roads, and omission of byways and dead ends is deliberate and justifiable. Even so, the amount of information and opinion packed into 550 pages is extraordinary.

Bell's facts are almost always sound, his style is clear and exuberant, his opinions, whether we agree with them or not, are expressed forcefully, often with humour and a little gentle malice. He was no uncritical hero-worshipper, being as quick to mark the opportunity lost as the ground gained, so that from his books we get a vision of mathematics as a high activity of the questing human mind, often fallible, but always pressing on in the never-ending search for mathematical truth.

T. A. A. BROADBENT

NEWS and VIEWS

Royal Geographical Society: Medals and Awards

H.M. THE QUEEN has approved the award of the Royal Medals for 1961 of the Royal Geographical Society as follows. *Patron's Medal:* Mikhail M. Somov, deputy director, Arctic and Antarctic Research Institute, Leningrad, for polar exploration and research; *Founder's Medal:* John Bartholomew, editor, *The Times Atlas of the World,* for contributions to cartography.

The Council of the Royal Geographical Society has made the following awards. *Victoria Medal:* Prof. W. William-Olsson, Stockholm School of Economics, for contributions to economic geography; *Murchison Grant:* Prof. K. M. Buchanan, University College, Wellington, New Zealand, for contributions to economic geography; *Back Grant:* Eric H. Brown, University College, London, for geomorphological research; *Cuthbert Peek Grant:* Martin W. Holdgate, Scott Polar Research Institute, Cambridge, and leader of the Royal Society's Expedition to southern Chile; *Gill Memorial:* Cuchlaine A. M. King, University of Nottingham, for glaciological and coastal research; *Mrs. Patrick Ness Award:* R. M. L. Mason and A. R. Hanbury-Tenison, for their trans-continental exploratory journey in South America.

Statistics at Birkbeck College, London: Prof. D. R. Cox

THE establishment of a chair in statistics at Birkbeck College, University of London, marks the fulfilment of a scheme the authorities have had in mind for some few years of establishing statistics at the College. Birkbeck College is a college of the University of London reserved for students who are in full-time occupation, so that the majority of the students attend only in the evening. In the past, the object of the College was to provide a university education for students who, for financial or other reasons, were unable to secure this in the normal way; but the development of university education in Britain has introduced many new elements. It is now much easier for a student to secure full-time education; on the other hand, there is now a need for many more men with qualifications in two allied subjects, and the College is finding that more and more of its students are fitting into this class. In particular, there are many who have taken degrees in mathematics who wish to obtain a qualification in statistics, and in developing this new department, the College has the needs of these students particularly before it. The department will provide courses for postgraduate and undergraduate students.

Dr. D. R. Cox, reader in statistics in the College, has been appointed to the new chair. His interests are the scientific and technological applications of statistics and probability, and the theory of statistics. His published work includes a book on the *Planning of Experiments* and he is joint author of a book on the theory of queues to be published shortly. His present research interests include prediction theory, various applications of the theory of probability in operational research, and the design and statistical analysis of experiments.

Division of Pure Physics, National Research Council of Canada: Dr. D. C. Rose, O.B.E.

DR. D. C. ROSE has been appointed director of the Division of Pure Physics, National Research Council of Canada. Dr. Rose was born in Prescott, Ontario, in 1901, and gained his B.Sc. degree in 1923 and his M.Sc. degree in 1924 from Queen's University. He was awarded an 1851 Scholarship for study, under Rutherford, at Cambridge, where he obtained his Ph.D. degree in 1927. After continuing his work at the Cavendish Laboratory until 1928, he spent 1928–29 at the H. H. Wills Physical Laboratory, Bristol, and 1929–30 as a lecturer at Queen's University. In 1930 he joined the Division of Physics of the National Research Council of Canada. During the Second World War, Dr. Rose was seconded to the Department of National Defence, first as scientific adviser to the Chief of the General Staff, during 1943–45, and later, during 1945–47, as chief superintendent of the Canadian Armament Research and Development Establishment at Valcartier. Returning from war-time duties to the National Research Council, he established a laboratory in cosmic-ray physics, which he still heads. For his contributions to the war effort, Dr. Rose was made O.B.E. Dr. Rose was elected a Fellow of the Royal Society of Canada in 1936; he has served the Society for several years as secretary of Section III. He is a past president of the Canadian Association of Physicists, a member of the American Physical Society and a member of the Engineering Institute of Canada.

Building Contracts for Universities

IN his report to the University Grants Committee reviewing the methods used by universities of contracting and of recording and controlling expenditure, Sir Arthur Rucker has some fourteen conclusions relating to the recommendations of the Gater Committee. The appointment of a small project sub-committee for each major building project is generally desirable and now usual, and this sub-committee should have in mind both the user's need and the needs of economy. There is occasionally difficulty in finding suitable persons with business and financial experience from outside a university to serve on the council and committees of the university, but every effort should be made to do so. Universities should keep their needs for staff under review to ensure that they and their committees have the advice and assistance they require to maintain proper control in their expanded building programme. No university should include in the list of firms invited to tender for a building contract any firm to which, if it were the successful competitor, the university would not desire to award the contract. Undue economy in capital costs at the expense of maintenance costs would be regrettable, but in a well-designed building it should be possible, within a reasonable over-all cost, to use materials and methods that will avoid excessive future maintenance costs.

It is important that all possible means should be sought both to make the maximum use of costly university buildings and to avoid planning new buildings on too low a standard of student use. Economy will always best be served by avoiding a break in the continuity of construction, and this should normally be possible in the present enlarged building programmes. The control exercised by universities and their committees and by the University Grants Committee over variations in plan after tenders have been invited is firm, and it is essential it should remain so. The normal practice of universities is, and should continue to be, to invite competitive tenders on a fixed price basis; in suitable cases negotiated contracts may be advantageous. Methods of letting sub-contracts have varied, but none of the methods used appears to have caused difficulty. The selection of sub-contractors before the letting of the main contract is, however, desirable. It is usually necessary to specify the date by which a contract is to be completed in the tender form, but the date should not be a matter for competition. The present practice of providing a sum for contingencies not exceeding 3 per cent appears to be generally satisfactory to universities, and is satisfactory so long as it is used for true contingencies and not for changes in plan. Architects should be required by all universities to make regular written reports to the responsible committees at least once a month, and in all universities the responsible committee should be provided at regular intervals with figures showing the estimated final commitment on each major contract. The general features of the Rucker Report are discussed elsewhere in this issue of *Nature* (p. 427).

Student Wastage in Australia

ACCORDING to a *Times* correspondent, Prof. R. Le Fèvre, professor and head of the School of Chemistry in the University of Sydney, has stated that that University failed 1,000 first-year students who sat for chemistry examinations in 1960. Prof. Le Fèvre said that if failures in other science subjects were included, the failure-rate would be about 50 per cent. There were too few lecturers and too many students. "We have a British university system imposed on an American schooling system. What we need is something like the American junior college system or the British sixth form which provides a suitable bridge between high school and university." Prof. Le Fèvre said that some students did not know how to work and some just wanted to have a good time. The only solution appeared to be the introduction of some kind of pre-selection system.

There seems to be little doubt that, so far as science, in any event, is concerned, the Australian system needs serious overhauling. Far too much time, money and space are wasted in the training of first-year students. This is, of course, to the detriment of standards within the university itself; but even worse is the fact that such student failures have apparently wasted one year of the most formative phase in their lives.

International Laws on Nuclear Incidents

THE Convention on Third Party Liability in the Field of Nuclear Energy, of July 29, 1960, was signed at Paris by the Governments of the West German Federal Republic, Austria, Belgium, Denmark, Spain, France, Greece, Italy, Luxembourg, Norway, the Netherlands, Portugal, the United Kingdom, Sweden, Switzerland and Turkey. The text of the Convention, which has now been published by the Organization for European Economic Co-operation, contains 24 articles (Pp. 67. Paris: O.E.E.C., European Nuclear Energy Agency, 1960). Its scope is limited to risks for which common law rules and practice are unsuitable, and it does not apply to nuclear incidents occurring in the territory of non-contracting States or to damage suffered in such territory. Its special regime applies only to nuclear incidents occurring at or in connexion with certain nuclear installations or in the transport of nuclear substances as defined. Risks which arise in respect of radioisotopes used for any industrial, commercial, agricultural, medical or scientific purpose are excluded, once the radioisotopes are applied for those purposes, as such risks are not exceptional: nuclear propulsion and nuclear fusion are also excluded, for different reasons. All liability for installations is channelled on to the operator of the nuclear installation where the incident occurs, while liability for incidents in transport falls either on the carrier or on the operator of the nuclear installation concerned. There are detailed provisions determining the kind of damage which will be compensated, and maximum liability in respect of any single incident has been fixed at 15 million European Monetary Agreement units of account, and rights of compensation are extinguished ten years from the date of an incident if no action has been brought before a competent court.

Detection and Identification of Underground Explosions

In connexion with the work of the conference on nuclear test control at Geneva, the Government recently announced its intention to carry out a programme of seismic research bearing on the detection and identification of underground nuclear explosions. This programme is now being planned in detail by the U.K. Atomic Energy Authority and suitable areas for the siting of seismic measuring instruments are being investigated. The research programme will involve the firing of conventional explosive charges, but no nuclear explosives will be used. Some of the firings will probably take place in disused mines and quarries: others may take the form of charges dropped at selected points in the Channel from naval vessels. An operational centre for seismic work is being established at a converted country house a few miles from Aldermaston.

The Field Studies Council

A wide range of courses dealing with many topics has been arranged by the Field Studies Council for 1961. At certain periods, normally March–Whitsun, there is great pressure on accommodation at the Centres and priority is given to members.

The Easter courses for schools are now designed for second- and third-year sixth-form pupils only. For pupils in secondary modern schools, a number of countryside courses have been arranged. The programmes again include a choice of courses specially designed for teachers in primary, secondary modern and grammar schools. At all times, even when courses have been arranged, places are kept for artists, amateur naturalists and other individuals or groups who wish to organize their own programme or to pursue studies independently, or in a less formal way than is suggested by the word 'course'. The Council has at its disposal a small bursary fund which is available to reduce the fee charged in individual cases of merit where grant-aid is needed but is not obtainable. Among the more unusual courses is that at Dale Fort for teachers dealing with marine biology and oceanography as well as "Man in Pembrokeshire", a course in historical geography. At Flatford Mill a course is to be run for amateur entomologists introducing them to field techniques in insect ecology. Juniper Hall has a course on slugs and snails, while Malham Tarn has a special course on karstic landforms as well as one on spider ecology. Students of geomorphology will find a special course at Preston Montford, while Slapton Ley provides an introduction to field archæology. Details of these, as well as the more routine, courses may be obtained from the Publicity Secretary, Field Studies Council, Ravensmead, Keston, Kent.

Biology, Psychology and Belief

The fourteenth lecture in memory of Sir Arthur Eddington was delivered in Cambridge on November 3 by Dr. W. H. Thorpe. Dealing with the relationships between the biological sciences and religious belief, Thorpe's lecture takes a rightful place among the more outstanding of its predecessors. To this lecture Thorpe has brought an honesty of purpose which should be of considerable help to biologists confronted with difficulties in reaching some general system of faith. There is also a clarity of thinking which is concerned never to confuse but to paint a world of the spirit as revealed to Thorpe. That man is a biological, as well as a spiritual, organism is well brought out, as is the conviction that no system of faith or belief has any ultimate prospect of securing the loyal and lasting adherence of educated men in the twentieth and later centuries unless it is firmly rooted in biological fact. The lecture has now been published as a booklet and should appeal to readers of all disciplines concerned with the nature of spiritual belief (Pp. 60. Cambridge: At the University Press, 1960. 4*s.* 6*d.*).

Rock Shelters of the Lower Murray River

A recent issue of the *Proceedings of the Royal Society of Victoria* contains an interesting account of an excavation undertaken at Fromm's Landing on the Lower Murray River under the leadership of D. J. Mulvaney, of the University of Melbourne (New Series, **72**, Pt. 2. Victoria: The Royal Society, 1960). A rock-shelter, facing east and well suited for habitation, was explored and no less than ten different levels determined. Not enough attention has been paid by prehistorians to recent work in Australia. Maybe the finds in various regions of Africa have too exclusively engrossed their attention. Australian Stone-Age sites have been dismissed as early native. The carbon-14 method of dating has many pitfalls and cannot always be entirely relied on unless many samples from a culture-level (and not all from the same site) have been examined. But the chances of reasonable accuracy are increasing as workers in the field are learning what precautions must be taken in procuring samples, and in the laboratory new techniques are being developed. The carbon-14 results for the lower levels at Fromm's Landing suggest a date some 4,000 years ago and one which therefore falls well within most prehistorians' periods.

Fromm's Landing is not the only site on the Lower Murray which has been explored: there is the Devon Downs shelter, with which Fromm's Landing can be compared, and there are others. As is to be expected, there are differences in the finds, both implements and fauna, as one proceeds from the top layer to layer 10. But these differences do not appear to be startling. Actually the site is not prolific in artefacts, but adzes, 'pirri' points (small, somewhat thick-based arrow-head-like affairs), microliths of various kinds and bone objects have been collected, as well as the bones of various mammals, reptiles, birds and fish. Naturally, too, shells, both univalves and bivalves, occur. On the walls of the shelter there are some rough markings, but these are scarcely worthy of the designation 'art'. The article is illustrated and the numbers under each illustration of a tool refer to accounts of them given in the text. There are, however, several such accounts referring to numbers which do not appear among the illustrations. Has a page of illustrations by accident been left out? The author is to be congratulated on an excellent piece of work. Should some of these habitation sites in Australia really date back to several thousands of years ago, it is high time geologists there took the matter up and determined a sequence of climate changes for the various areas in the continent. It is scarcely conceivable that no perceptible changes have taken place over so long a period. The correlation of such a climate sequence with the study of the stone industries from the various levels would mean an important addition to knowledge.

Birds of the Philippine Islands

It is known that the size of an island may be an important factor in determining certain characteristics of its avifauna. Recently, A. L. Rand and D. S. Rabor have directed attention to "a surprising but apparently very real phenomenon in the Philippines", namely, that species commonly restricted to higher altitudes may live at lower ones on small islands (*Fieldiana*: Zoology, **35**, No. 7, 221. Chicago: Chicago Natural History Museum, 1960. 4 dollars). Thus the fruit pigeon *Ptilinopus merrilli* is a mountain bird on Luzon, but lives at sea-level on the adjacent small Polillo Island; and there are similar cases. The brush cuckoo *Cacomantis variolosus* is of special interest because it lives on the mountains of Zamboanga, a large island of which the lower levels are inhabited by the related *C. merulinus*; on Siquijor (90 square miles) only *C. variolosus* is found, living far below what is regarded as its normal range. This observation may be considered with the known fact that there are species of wide distribution in south-east Asia which live only on small islands, the nutmeg pigeon *Ducula bicolor* being an example of this in the Philippine archipelago. The speculation is made whether a restricted montane habitat surrounded by lowlands may not in some way be equated to a small insular habitat surrounded by sea.

New Species of *Chaetacis* from South America

While working on collections of spiders in the British Museum (Natural History), Arthur M. Chickering of Albion College, Albion, Michigan, found numerous examples of the genus *Chaetacis* from South America. Chickering separated out specimens which appear to represent five new species, thus bringing the total number of known species to twelve. Two of the new species, which he describes in the August issue of *Annals and Magazine of Natural History* (2, No. 20; 1959), are represented only by males which have not previously been described, although apparently Eugene Simon saw one when he established the genus in 1895. The types are to be deposited in the Department of Zoology, British Museum (Natural History).

Measurement of Molecular Weights

An easy-to-operate device for the accurate determination of molecular weights of unknown materials in solution has been developed by R. A. Pasternak and Leonard A. Cavanagh, and is described in the November–December issue of *Research for Industry* (12, No. 6; 1960). This efficient analytical tool is also valuable for research on interactions of compounds in solution. The key to the instrument is a thermostatically controlled chamber, the atmosphere of which is saturated with the vapour of a solvent. A probe composed of two bead thermistors is enclosed. Drops of the solvent and of the sample solution are applied to the beads through one of the six syringe assemblies of the unit. At any given temperature the vapour pressure of a solution is lower than that of the solvent. Therefore, the solution drop warms up (by condensation of minute amounts of the solvent) until pressure balance between the two drops is attained. The temperature rise, detected by the thermistor probe, is about proportional to the 'osmotic concentration' of the sample solution. When the instrument is calibrated with solutions of known concentration, it is then possible to calculate the molecular weight of the unknown solution. The new instrument, which was developed for Mechrolab, Mountain View, California, has great advantages over present molecular weight devices. Because of the syringe assembly, it does not have to be opened after each sample. Indeed, duplicate readings can be taken on fresh samples within 1–5 min. An accuracy of 1–2 per cent is claimed. Moreover, only very small amounts of the sample are required for testing.

Fiftieth Anniversary Meeting of the Biochemical Society

The fiftieth anniversary meeting of the Biochemical Society is to be held during March 27–29, and will be centred on University College, London. The meeting will include a symposium and a memorial lecture. The symposium is to be on "Structure and Synthesis of Macromolecules" (March 27–28), and will be opened by Prof. F. G. Young (Cambridge). Among the other speakers are: Prof. P. Doty (Harvard); Prof. J. N. Davidson (Glasgow); Prof. E. L. Hirst (Edinburgh); Prof. W. Z. Hassid (Berkeley); Dr. M. F. Perutz (Cambridge); Prof. E. L. Smith (Salt Lake City); Prof. J. Monod (Paris). The third Hopkins Memorial Lecture will be given by Sir Hans Krebs, and is entitled "The Physiological Role of Ketane Bodies" (March 28). The annual general meeting and anniversary dinner will take place on March 29. Further information can be obtained from the honorary secretary, Dr. W. J. Whelan, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1.

City of Liverpool College of Technology

It is announced that the following are to become honorary associates of the College: Mr. F. W. Adams (secretary and registrar of the Pharmaceutical Society of Great Britain); Sir Edward Bullard (Department of Geodesy and Geophysics, University of Cambridge); Mr. E. Le Q. Herbert (president of the Royal Institute of Chemistry); Sir Alan Tod (president of the Liverpool and District Scientific, Industrial and Research Library Advisory Council).

University News: McGill University

THE research groups and weather observatory which have been responsible for the meteorology carried out at McGill University have now been supplemented by a Department of Meteorology, consisting of Profs. J. S. Marshall and F. K. Hare, Associate and Assistant Profs. R. H. Douglas, W. Hitschfeld, S. Orvig and B. W. Boville. In the undergraduate curriculum, four continuation courses in meteorology are available to the general programme toward the B.Sc. degree. For the postgraduate programme leading to the M.Sc., the normal admission requirement is a bachelor's degree with honours in physics, and there is no prerequisite meteorology. Candidates proceeding from master's degree to Ph.D. will continue as in the past to be primarily the concern of the research groups, with the possibility of some helpful backing from the Department. Prof. Marshall retains his title and duties as Macdonald professor of physics, and Prof. Hare continues as professor of geography and chairman of that Department. Profs. Boville and Orvig are known for their work in the Arctic Meteorology Research Group, and Profs. Douglas and Hitschfeld in connexion with the Stormy Weather Group. Until the present session, Dr. Douglas and Mr. Boville have been at McGill as members of the Canadian Meteorological Service, to which they have made important contributions. By the end of the present session their formal connexion to the Service will have been severed, but there will be close and continuing co-operation between this first Canadian University Department of Meteorology and the Canadian Meteorological Service.

Sheffield

Two new lectureships have been announced: Mr. A. Usher is to be lecturer in forensic medicine; and Mr. H. Merskey, to be lecturer in psychiatry.

Swansea

DR. J. D. WESTON, senior lecturer in mathematics, King's College, Newcastle upon Tyne, has been appointed professor of pure mathematics, to succeed Prof. R. Wilson, who retires at the end of the present session.

A one-year course, leading to a College diploma in chemical engineering, will be instituted in the session 1961–62. It will be open to students holding an honours degree, or equivalent qualification, in a branch of physical science or engineering, and the content of the course will be adjusted according to the background of the individual student. It will consist of lectures, tutorials, laboratory and design work, extending over a full academic session. Applications should reach the Registrar, University College, Swansea, by June 30.

Announcements

SIR JOHN COCKCROFT, master-designate of Churchill College, Cambridge, and part-time member of the U.K. Atomic Energy Authority, has been awarded the 1961 Atoms for Peace Award, for his contribution towards the application of atomic energy to the production of electricity in the United Kingdom. The Award, established as a memorial to Henry Ford and his son Edsel, consists of a gold medal and 75,000 dollars.

PROF. EPHRAIM KATCHALSKI, head of the Biophysics Department, Weizmann Institute of Science, has been awarded the Rothschild Prize for Research for 1960, in recognition of his work on the structure of poly-amino-acids.

MR. S. N. MITRA, of the Research Department, All India Radio, New Delhi, has been awarded the 1960 prize of the Council of the Institution of Telecommunication Engineers of India for his paper, "Magneto–Ionic Triple Splitting over Delhi".

PROF. W. T. ASTBURY, professor of biomolecular structure in the University of Leeds, has been elected the fourth recipient of the T. Duckett Jones Memorial Award. This is a medical award of 6,500 dollars administered by the Helen Hay Whitney Foundation, and it will be presented to Prof. Astbury at Princeton, New Jersey, on October 7, 1961.

MR. E. LL. HARRY, at present regional controller of the East Midland Region of the Ministry of Agriculture, Fisheries and Food, is to succeed Mr. C. D. Ross as regional director of the National Agricultural Advisory Service, South Western Region, when the latter retires on March 9.

A SYMPOSIUM and instrument exhibition on "Automatic and Semi-Automatic Methods in Analysis and Control" will be held at the Medway College of Technology on March 16. Further information can be obtained from the course organizer, Dr. D. T. Burns, Department of Science, Medway College of Technology, Maidstone Road, Chatham, Kent.

THE Faraday Society is organizing a general discussion on "Radiation Effects in Inorganic Solids" by invitation at the Centre d'Études Nucléaires de Saclay, Gif-sur-Yvette (S.-et-O.), during April 11–12. Further information can be obtained from the Assistant Secretary, Faraday Society, 6 Gray's Inn Square, London, W.C.1.

AN intensive short course in elementary plasticity is being organized by the Imperial College of Science and Technology, in the Department of Mechanical Engineering, during April 10–14. Further information can be obtained from Dr. J. M. Alexander, Department of Mechanical Engineering, Imperial College of Science and Technology, Exhibition Road, London, S.W.7.

THE Faraday Society is holding an informal discussion on the "Mechanisms of the Gas-Phase Reactions of the Halogens and their Compounds" in the Chemistry Department, University College, Cardiff, on March 28. The programme will be divided into two sections: (*a*) oxidation processes; (*b*) reactions of elementary halogens. Further information can be obtained from Dr. J. H. Thomas, Chemistry Department, University College, Cathays Park, Cardiff.

ERRATUM. In *Nature* of January 28, p. 275, concerning recent changes in administration and organization of the Akers Research Laboratory, Imperial Chemical Industries, Ltd., it was erroneously stated that Dr. Chatt will continue in charge of the Organic Chemistry Department; Dr. Chatt is in charge of the Inorganic Chemistry Department.

NEW LABORATORY OF LONDON TRANSPORT

By A. T. WILFORD

Director of Research

A NEW laboratory situated on London Transport's Chiswick Works Estate was officially opened by Mr. A. B. B. Valentine, chairman of the London Transport Executive, on December 5. It will continue the function of providing a scientific service available to all departments of London Transport and will permit an expansion of these facilities, with particular reference to engineering problems. At the same time, the small laboratories concerned with essential day-to-day chemical control at the three generating stations are being retained.

The history of the Chiswick Laboratory goes back to more than forty years ago, when a small laboratory was established by the former London General Omnibus Co. at Farm Lane, Fulham, primarily for testing petrol and lubricating oils. It was transferred to Chiswick Works, then newly opened, in 1,921. The scope of its activities, mainly in the chemical field, gradually extended, and improved accommodation was provided in 1931. By the time that the London Passenger Transport Board was formed in 1933 the laboratory was beginning to provide a service also for departments of the undertaking other than those concerned with road vehicles, and in 1949 it became officially recognized as London Transport's Central Laboratory. Immediately prior to its transfer to the new premises, the Laboratory was housed in portions of four scattered buildings and three temporary huts on the Chiswick Works Estate.

The new Laboratory premises (Fig. 1) comprise a steel-framed two-storey building with an adjacent single-story annex, the total floor area being 27,000 sq. ft. Metallurgical, physics and engineering activities are housed on the ground floor, the chemical sections and general administration being located on the first floor. The single-storey annex contains a shop for manufacturing special chemical mixtures, also a pilot plant shop. Its roof is linked by a bridge to the first floor of the main building and serves as a site for weather exposure testing of paints. (A second exposure testing station, where conditions are somewhat more adverse, is maintained on the roof of the Executive's Upton Park Garage.)

Except in the engineering laboratories and workshops, the services, which include gas, electricity,

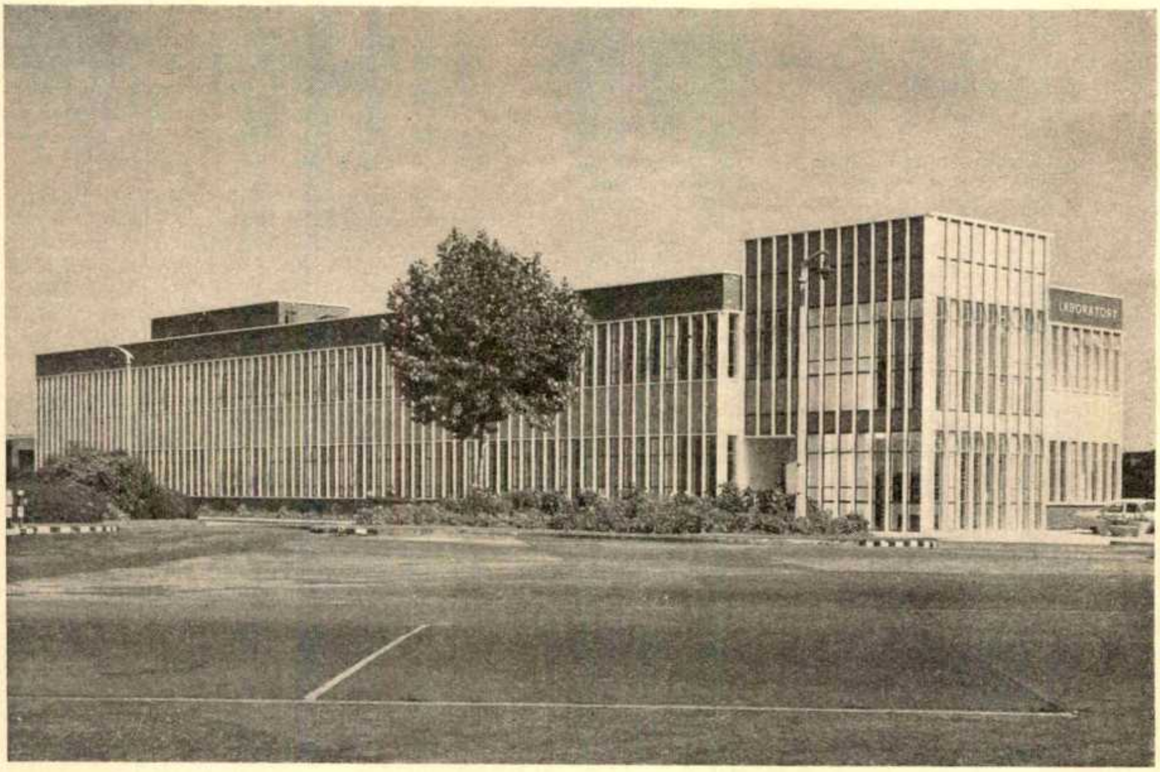

Fig. 1. New Laboratory of London Transport at Chiswick

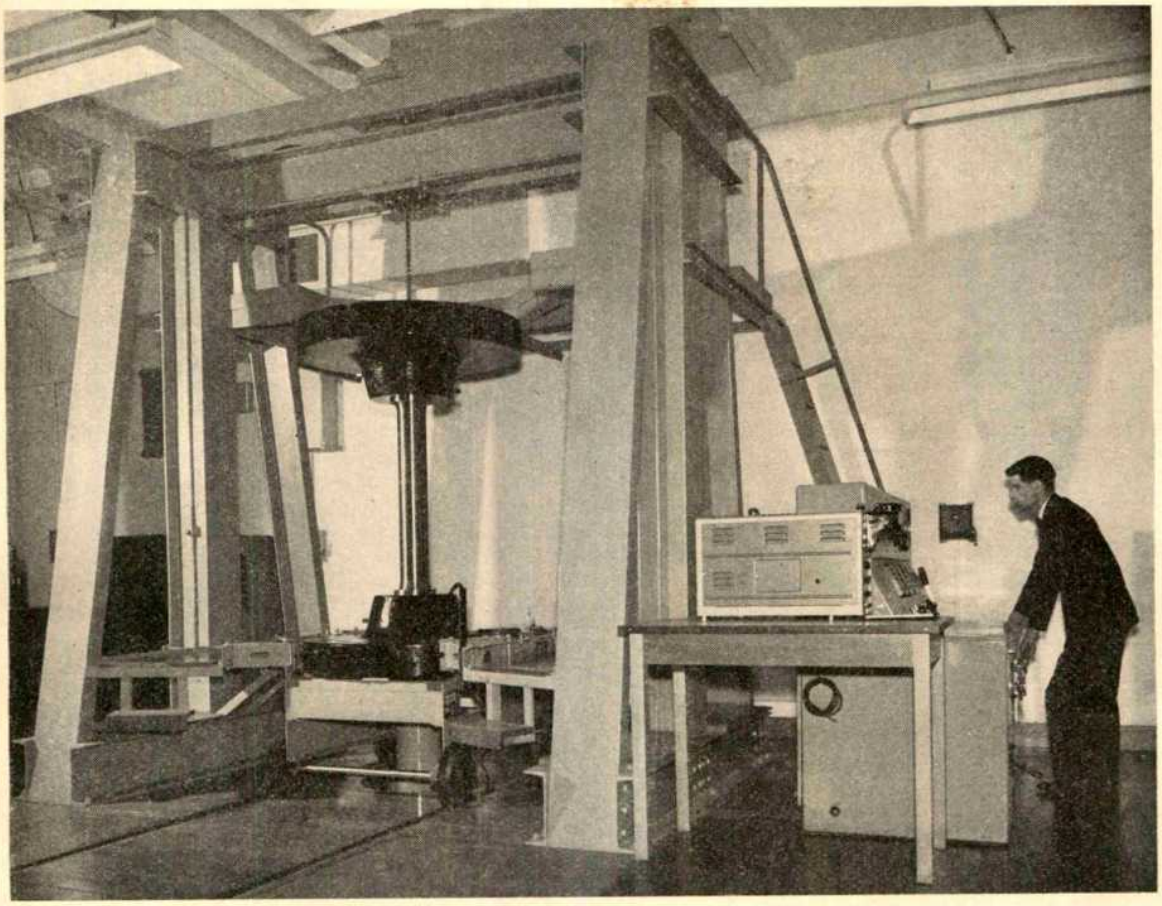

Fig. 2. Fatigue testing machine developed in the University of Nottingham

steam, hot water and pressurized cold water, are carried above removable ceiling panels, and the use of ceiling heating permits the most efficient use of laboratory floor space. Air extracted through fume cupboards, etc., is replaced by means of a plenum system which introduces air at a pre-adjusted temperature. Certain rooms are also provided with air-extraction systems.

The laboratory is concerned with chemical and physical control of supplies, technical control of works' processes and the investigation of many day-to-day problems which arise in the course of operation and maintenance of London Transport's services and where the specialized facilities available are likely to be of help. This work is essentially of a short-term character, but longer-term investigations are also undertaken, and special mention may be made of the pioneer work relating to the application of low-viscosity oil for lubrication of bus engines and improved lubricants for worm-driven axles; much work has also been done in connexion with lead–acid accumulators, in regard to fatigue failures of railway car axles, and on other problems relating to railway rolling stock and the permanent way.

The facilities for metallurgical work include a metals-chemistry laboratory, a laboratory for mechanical testing, a specially screened room with barium block lining for radiography, also rooms for macro- and micro-examination of metals and for technical photography. Equipment for heat treatment and welding tests is situated in the pilot plant shop. A well-equipped machine shop provides a service for all sections of the laboratory.

The physics laboratories include rooms for testing of batteries, photometric testing of electric lamps, non-destructive testing, high-voltage tests and construction and calibration of instruments. A cold chamber, 14 ft. × 9 ft. × 8 ft. high, is available for tests on equipment at temperatures down to about 0° F.; it can also be adapted for tests at elevated temperatures up to 120° F.

The chemical division of the Laboratory comprises three sections dealing respectively with fuels and lubricants, paints and protective processes and general chemistry, the latter being concerned with all chemical work other than that falling to the specialized sections. Separate 'general' and 'research' laboratories are provided for these various functions. In addition to its normal equipment, the fuels and lubricants section is equipped with an automatic oil oxidation apparatus, equipment for mechanical testing of lubricants and a small engine for determining the ignition quality of road-vehicle fuel. Equipment for testing paints includes a spray booth, stoving oven, an accelerated weathering machine and other apparatus for accelerated tests. There are also various instruments for physical testing, and a special room with direct access to the outdoor exposure station is provided for application tests, on which great emphasis is placed.

A textiles sub-section comprises a room for chemical and general examination of textiles and an air-conditioned room for physical tests, the equipment of which includes a tensile testing machine with autographic recorder, a horizontal fabric strength tester and apparatus for abrasion tests, flex resistance and bursting strength.

The largest item of equipment at present installed in the laboratory is a fatigue testing machine which has been specifically designed to investigate the fatigue strength of railway car axles (Fig. 2). The machine has been developed at the University of Nottingham to determine the strength of specimens of axle steel when subjected to a rotation bending stress. There is a 'scale effect' of uncertain magnitude in fatigue and the machine is therefore designed to test specimens of typical axle sizes, namely, 6½ in. diameter. It is the intention initially to investigate the effects on fatigue strength of surface rolling and, later, the effect of shrink fits. The influence of composition of the steel and heat treatment will also be investigated.

The machine is of the resonant type, with a mechanical drive via a slipping clutch to permit starting and stopping. The specimen is about 5 ft. long × 6½ in. diameter with enlarged ends. Each end is secured in a heavy disk. The assembly of two heavy disks and the specimen as a spring has a natural frequency for transverse bending of the specimen just below 50 c./s. The assembly is freely suspended from the centre of one disk by a wire rope with the specimen vertical. The lower disk carries below it a rigid extension tube. If the lower end of this tube is made to move in a circular path at a speed corresponding to the natural frequency, the assembly is caused to vibrate and so give a rotating bending stress on the specimen. The stress is measured by resistance strain gauges, calibrated in position, and a number of protective devices are included so that the machine may be left running unattended. Two specimens have already been tested in the machine. One failed at a stress not much greater than the expected fatigue limit (2,910,000 cycles at 16 tons/in.^{2}). The other failed at a higher stress (640,000 cycles at 20 tons/in.^{2}). Both specimens were afterwards broken open by static bending to expose the fatigue-fractured surfaces.

The laboratory when up to strength will have a total staff of about eighty of all grades, one-third of whom will be graduates or otherwise professionally qualified.

TEXTILE RESEARCH INSTITUTE OF THE BOMBAY TEXTILE RESEARCH ASSOCIATION

By Dr. C. NANJUNDAYYA
Joint Director

THE cotton textile industry is one of the foremost organized industries in India and it has been playing its many-sided part making an increasingly valuable contribution to the country's economy and progress.

Although the need for organizing research on a co-operative basis was well recognized by the textile manufacturers of India long ago, the financial resources of the industry were not sufficiently encouraging to undertake any scheme in this behalf. It was only during and after the Second World War that impetus was given by the Government of India to promote and organize textile research. In order to implement this, the Government of India promulgated the Cotton Textiles Fund Ordinance in 1944, and constituted the Cotton Textiles Fund Committee for administering the funds raised by the levy of customs duty on yarn and cloth exported from India. This Committee, after due deliberations, decided to establish four textile research institutes, one in each of the four zones, into which the country was divided, and mills situated in Zone I, comprising the old Bombay State to the south of River Tapti, Madhya Pradesh and Hyderabad, were allotted to the jurisdiction of the Bombay Textile Research Association. It was further decided that, in the first instance, two research institutes, one at Bombay and another at Coimbatore, be established, ATIRA at Ahmedabad having already come into existence.

The Millowners' Association, Bombay, then took steps to formulate a scheme for establishing a Textile Research Institute at Bombay. Although the Bombay Textile Research Association was registered in 1954 under the Societies Registration Act, 1860, the preliminaries connected with the acquisition of a suitable plot of land, planning and other formalities connected therewith took some time. The actual construction of laboratory premises was commenced in 1958 on a 23-acre plot of land situated in very pleasant surroundings at Ghatkopar, a suburb of Bombay.

As the construction of the buildings and installation of the pilot plant and laboratory equipment were expected to take two or three years, at the instance of Dr. C. Nanjundayya, joint director, a building was taken on rent in 1958 and such technical work as could be carried out in the mills, namely, standards engineering, statistical quality control, technical liaison, physical and chemical testing, T.W.I., and dissemination of current technical literature, was commenced. As a result of the work done so far, the mills have begun to realize the benefits accruing to them from the Research Association.

The original scheme of the Textile Research Institute envisages a capital expenditure of about Rs. one crore (£750,000) and recurring expenditure of about Rs. 12 lakhs per annum (£90,000).

The scope of work of this Institute covers the entire field of textile research, comprising fundamental and applied research in the mechanical and chemical processing of cotton as well as man-made fibres, operational research, including statistical quality control and human relations, technical liaison for communication of results obtained in the laboratories to the mills and of mill problems to the Bombay Textile Research Association laboratories, an up-to-date technical library and dissemination of technical knowledge to mill technicians, and research in textile engineering.

The present built-up area of the buildings is about 100,000 sq. ft., which is approximately two-thirds of the area that is proposed to be built according to the original scheme.

It was on December 9 that the President of India, Dr. Rajendra Prasad, inaugurated the Textile Research Institute of the Bombay Textile Research Association. Dr. Rajendra Prasad was welcomed by Mr. Krishnaraj M. D. Thackersey, chairman of the Association; in doing so, he stressed the importance of research to the textile industry and said that it could profitably be carried out by co-operative organizations like the Bombay Textile Research Association, which has thirty-six large cotton mill companies as members. He further said that it was the desire and determination of the Research Association to see that the research and development work carried out in this Institute would materially help the textile industry not only to maintain its present level of prosperity but also to enable it to achieve further progress and prosperity.

Dr. Rajendra Prasad, in his opening address, appreciated the co-operative effort of the textile mills in the establishment and maintenance of the Research Institute for their common benefit, and said that it would supplement the general policy of the Government of India to encourage and undertake research in all fields. He was happy to know that the Association had the support of a large number of mills, and he had no doubt that the research done by the Research Institute would benefit the manufacturers, the consumers and the country at large.

Mr. Ramnath A. Podar, deputy-chairman, proposed a vote of thanks to the President, and Dr. C. Nanjundayya read a few of the large number of messages of good wishes received on the occasion from distinguished persons and institutions in India and abroad.

SECONDARY EDUCATION IN INDIA

IN 1952 the Government of India appointed a Commission (the Mudaliar Commission) to examine the prevailing system of secondary education in the country and to suggest measures for its reorganization and improvement. It is about six years since the report of the Commission and its recommendations have been before the public. These are now being considered for implementation by the State Governments under guidance and financial assistance from the centre (*Sci. and Culture*, 26, No. 4, 1960).

According to the new scheme for an eleven-years school course, education in secondary schools extends over 6–7 years. It is to be regarded as a complete unit by itself, and not merely a preparatory stage for the university and technical education.

This pattern of education has been framed generally after that of British countries, but it also includes some features of the American and Soviet systems.

The British pattern differs from that of the United States by providing for specialization at the secondary stage. In the United States, the secondary schools cater for a purely general, or academic, education as a preparatory step for admission to colleges in the university, and/or a vocational course as a preparation for earning a livelihood. The schools in the British countries provide both for those going on to universities and for those going directly into industries and commerce, or the public service.

The Commission has also borrowed some special features from the Soviet system of secondary education. This relates to the introduction of training for some crafts and fine arts in the curriculum so that instruction might be combined with some productive work.

The secondary school curriculum in India, now recommended, is a diversified one. A certain number of core subjects are, however, common to all students, irrespective of the diversified course of study taken by them. These are: (1) languages, (2) general science, (3) social studies, and (4) a craft. The diversified course of study consists of seven groups, namely (1) humanities, (2) sciences, (3) technical studies, (4) commercial subjects, (5) agricultural subjects, (6) fine arts, and (7) home sciences. Three subjects from any one of these groups are to be taken along with the core subjects.

A study of two languages has been recommended for the high and higher secondary stages. One of these must be the mother tongue or the regional language which forms the medium of instruction throughout the secondary stage. English and Hindi have been recommended for introduction in the earlier or lower secondary stage. English and Hindi have to be studied as compulsory languages by all, besides the regional language or the mother tongue.

The introduction of the higher secondary course has given rise to many serious problems, owing to the dearth of competent science teachers, the lack of proper laboratory facilities and equipment, and the shortage of suitable text-books in science subjects with precise descriptions of terms and terminologies for the regional languages.

A sudden increase in the school population at the end of the secondary stage, likely to result from the introduction of the eleven years school course, is another problem that has to be faced. Many of those coming out of the secondary schools will fail to find admittance to the university and professional colleges or the polytechnics; nor are they likely to be absorbed in sufficient numbers in government services or industries. The result will be an increase in unemployment. Though India is generally backward in education and has a literacy of only 17·5 per cent of the population as a whole, its relative position at the secondary level is abnormal in comparison with that of the most advanced countries of the world.

For every thousand students in the primary schools the number at the secondary and university stages for different countries are indicated in Table 1.

The structure of secondary education on India with a literacy of about 18 per cent of the population as a whole rests on an abnormally shrunken and narrow base. This represents instability, and is responsible for the comparatively poor standard of efficiency of the educational system. The remedy lies in the introduction of free and compulsory primary education as early as possible.

Secondary education for girls also represents a serious problem in India. The Mudaliar Commission is not in favour of making any distinction between education imparted to boys and girls in the secondary

Table 1

	No. of students per thousand		
	Primary stage	Secondary stage	University stage
India, 1956	60	23	1·8
China, 1955	87	7 4	0 5
Japan, 1956	144	90	6 8
West Germany, 1956	97	72	2 5
France, 1954	114	30	3·5
United Kingdom, 1954	108	49	1 6
U.S.S.R., 1958	125	38	10 5
United States, 1955	154	48	0 16

	No. of students	
	Secondary stage	University stage
India, 1956	364	30
China, 1955	84	5 6
Japan, 1956	628	47
West Germany, 1956	740	26
France, 1954	264	31
United Kingdom, 1954	463	15
U.S.S.R., 1958	300	84
United States, 1955	313	105

schools, but recommends special facilities for the study of home science for the latter. Separate schools for girls have been considered preferable at the secondary stage, and definite conditions have been laid down for mixed co-educational schools to satisfy the special requirements of girl students and women teachers.

The Secondary Education Commission has considered defects in the present system of teaching and examinations, and has recommended certain changes. These include: reduction in the number of external or public examinations, change in the type of questions giving preference to the objective type of tests over the subjective or essay type, maintenance of a proper record of school work for every pupil, credit for the results of internal examinations and for school records in the final assessments by public examination, provision for only one public examination at the completion of the secondary course, and for compartmental examinations in case of failures in one or more subjects.

Even the organization of a single State-wide public examination at the completion of the secondary course each year is a formidable task as the total number of candidates in any State in India may easily reach a very high figure.

THE BRITISH COUNCIL

THE feature article accompanying the general survey of the year in the British Council's annual report 1959–60 deals with the printed word*. In doing so it gives a most readable account of the work of the Council's libraries and the way in which they foster the demand for British books and periodicals abroad. It includes details of the Council's own publications, and the information work, book exhibitions and book reviews which are incidental or ancillary to these activities. A brief summary of the action taken by the Government to promote exports of British books and periodicals is included. Of some 7,000 periodicals published in the United Kingdom, the Council uses, with yearbooks, some 1,750 in its work abroad and maintains more than 32,000 subscriptions not only for its own libraries but also for presentations, on local advice, to a wide range of schools and colleges, research stations and societies.

The general survey of the year notes that the Council is undertaking the general reception, accommodation, finance and welfare of scholars coming to the United Kingdom under the Commonwealth Scholarship and Fellowship Plan, as well as a corresponding responsibility for teachers from the Commonwealth coming for courses at teachers' training colleges. It has also been asked to help with the recruitment of teachers for schools in Commonwealth countries and with recruitment to university posts. Among developments overseas during the year, those in India and Pakistan are particularly stressed; by the end of 1960–61 the Council will have libraries in eight towns in Pakistan, six of them being university towns, while the tour by a team of eminent representatives of science and medicine in Cairo and the United Arab Republic is likely to increase the exchange of academic and professional visits between the United Kingdom and the Republic. In February 1960 the Council resumed work in Cairo. The programme of exchanges in the educational, cultural and scientific fields drawn up in March 1959 in Moscow with the U.S.S.R. was for the most part carried out, and for the first time British postgraduate students have studied for a full academic year in the Universities of Moscow and Leningrad while Soviet students have studied in British universities.

Between July 1957 and March 1960 the Council directly recruited 253 teachers of English and other subjects in English for overseas, and awarded 280 scholarships for training teachers for overseas in the United Kingdom. The continuing need for this work is again stressed in the report, and summer schools for teachers of English arranged during the year in the United Kingdom were attended by more than 700 teachers from overseas, while summer schools arranged overseas were attended by some 2,000 teachers. Overseas visitors under the auspices of the Council number 6,040, of whom 1,231 were from the Commonwealth and 381 from the Colonies; of these 1,052 were in medicine, 1,359 in science and technology, 1,125 in social science and 1,589 in education. A higher proportion is now coming from the Indian sub-continent and the Far East, and a smaller proportion from Europe. The programme of study tours continues to expand, and, of the 65 such tours arranged during the year, 15 were in science and technology. Stress is also laid on the value of the many specialist tours and advising visits overseas by leading figures in many professions which the Council arranges, and in regard to science the report refers to the continued financing of the exchange of senior scientists and research workers between the Royal Society and the U.S.S.R. Academy of Sciences, while the Royal Society was also enabled to invite a delegation from the Roumanian Academy of Sciences to visit Britain. The Council's current policy on books and periodicals places greater emphasis on scientific, technical and medical text-books.

---

* The British Council. Annual Report, 1959–1960. Pp. vi+110+12 plates. (London: British Council, 1960).

The total number of overseas students in the United Kingdom is estimated at about 47,000, and during the year the Council met on arrival 8,137 students as well as 1,299 United Nations' Fellows, Colombo Plan trainees, etc., who were assisted to find accommodation. Permanent accommodation in lodgings was found for 3,417 students, and for 405 in Council residences, and temporary accommodation for 5,005 while on study visits, etc., apart from transit or temporary accommodation in lodgings or Council residences for many more. Some 9,878 students enrolled as members of Council Centres during 1959, 2,736 attended vacation courses of 7–15 days, 1,481 week-end courses, and 9,554 half-day or full-day study visits to factories, museums, etc.

A SCIENCE PLANNING BOARD

THE proposal that the Government should set up a Scientific and Technical Planning Board to give "better direction to our scientific effort" is one of the recommendations for immediate action by the Association of Scientific Workers in a policy statement, "Science and Education"*.

The statement declares that, "given an adequate structure there is no reason whatever to fear a shortage of suitable people for higher education in science and engineering and teaching. Considerable untapped resources exist". The number of women in British technical colleges is very small compared with men. This difference is by no means due to innate intelligence or leanings, but largely to social customs reflected in school policies exacerbated by the desperate shortage of science teachers in girls' schools.

The Association's statement lists five objectives: to make science a central subject throughout the school lives of all children; to expand considerably the provision of educational opportunities for children beyond the age of fifteen; to overcome the critical shortage of science and mathematics teachers; to achieve a larger annual output of scientists and engineers than the present Government's targets, as soon as possible; to raise considerably the annual output of technicians of all kinds.

The report states that the first and most fundamental need is to provide more science teachers in schools and in technical colleges, training colleges and universities—and the most acute need is in schools. The only permanent solution to a shortage is to raise the salaries of teachers. The Association believes that "the immediate critical shortage" could be alleviated by a government-led national programme of secondment or release of scientists and mathematicians from the Civil Service (including the defence departments), nationalized industries and universities to teach in schools while the 'bulge' passes through, and a national drive to bring more married women back into teaching.

Proposals are also made to have at least four, and preferably six, new university institutions before the end of the 1960's; to expand the work of the technical colleges; to improve conditions of service of technicians in higher educational establishments; to assist more students to train to be scientists; and to make the fullest possible use of trained scientists, technologists and technicians.

TOBACCO SMOKE RESEARCH

THE Tobacco Manufacturers' Standing Committee has as a declared aim the assistance of research into questions concerned with the relationship between smoking and health. That this object is being fulfilled is evident from its report for the year ended May 31, 1960, which summarizes investigations carried out during the year under the auspices of the Committee or with its financial support, including research into factors affecting smoking habits, the biological activity of tobacco smoke, factors affecting the incidence of lung cancer and certain other diseases and physiological and psychological aspects of smoking*. In addition to supporting these activities, the Committee has also made financial grants to the Medical Research Council and to the Institute of Cancer Research, Royal Cancer Hospital, London, for research into causes of lung cancer and into tumour viruses.

Fractions of cigarette smoke condensate prepared in the laboratories of the Committee have been found by several workers to have carcinogenic or tumour-promoting properties, but as the report points out, these results, obtained by application of smoke fractions to animal tissues, are not necessarily reliable guides to the possible response of human lung tissue to tobacco smoke.

Some of the investigations supported by the Committee have been stimulated by the suggestion of Sir Ronald Fisher that smoking habits may be influenced by genetic factors. It has been found in one investigation that the smoking habits of identical twins are more alike than those of non-identical twins, and other work into the personality characteristics of different types of smokers appears to confirm the view that genotypic differences exist between smokers and non-smokers and between cigarette smokers and pipe smokers.

The Committee has also published the first Supplement to its third research paper, "The Constituents of Tobacco Smoke: an Annotated Bibliography" (which is edited by H. R. Bentley and E. G. N. Berry)†. This useful compilation provides a convenient list of references, arranged in sections corresponding to chemical classes, covering the literature which appeared during 1959, and will be an invaluable guide to research workers in this field.

THE WOLFSON FOUNDATION

THE first report of the Wolfson Foundation, created in 1955, covers the first five years work of the Foundation*. So far, the Foundation has adopted as its principal aims the advancement of education and health in the United Kingdom and Commonwealth, with particular reference to scientific and technological education, building for higher education, youth activities, medical research and education, cancer research, and medical, surgical and nursing services not covered by the National Health Service. Up to July 1958 it was occupied by preliminary work, including the creation of the necessary administrative organization and a Board of Trustees of wide experience and enjoying general confidence. To November 30, 1960, grants totalling £3,311,110 had been made and grants totalling a further £237,500 were made in December 1960. These latter grants, which are listed on a separate sheet issued with the report, include £100,000 to St. Hilda's College, Oxford, for a residential block for 60 undergraduates, £52,000 in extension for three years of the £125,000 already granted to the National Playing Fields Association, and £5,000 to the Commonwealth Society for the Deaf for a rehabilitation centre in Eastern Nigeria.

Grants for education noted in the report include £250,000 for a new Commonwealth Hall of Residence for 400 men students at the University of London; £65,000 to endow the Wolfson chair of metallurgy at the University of Oxford; and £4,500 for a research fellowship in metallurgy there; £300,000 for a hall of residence for about 150 men students at the University of Glasgow; £70,000 for an assembly hall forming part of the main block of Churchill College, University of Cambridge, £150,000 for the establishment of the Institute of Criminology in the University of Cambridge; £75,000 for building and furnishing the library of St. Catharine's College, Oxford; £350,000 to the Imperial College of Science and Technology to build and equip laboratories for biochemistry and chemical microbiology and support teaching and research in these subjects; £210,000 to the Royal Society to endow a research professorship; £100,000 to New Hall, Cambridge, and £80,000 to St. Anne's College, Oxford. A grant of £2,000 to the Royal Institution is a contribution to the Institution's work in interpreting current scientific developments to the public.

Major grants in the field of health include £250,000 to the Westminster Hospital School of Nursing; £150,000 over 10 years to the British Empire Cancer Campaign in support of its researches; £150,000 to the Postgraduate Medical School, Hammersmith, for the Wolfson Institute containing lecture theatres, common rooms and other amenities for students and teaching staff; £184,000 for the Institute of Psychiatry associated with Maudsley Hospital, University of London; and £450,000 to the Royal College of Physicians for a new building containing a larger library, a main lecture theatre seating 300, a smaller lecture theatre, committee and common rooms, and a dining hall. A grant of £22,000 was made to Mr. Wylie McKissock, neurological surgeon at St. George's Hospital, London, for surgical research into anatomical and biochemical aspects of hæmorrhage of the brain.

A grant of £10,000 to the Royal Geographical Society is to be used during 1960–63 to encourage participation of young people in exploration. Miscellaneous grants include £2,500 to the Crofters' Commission, £4,631 to the British Museum to acquire a sculpture, discovered at Nineveh, showing Babylonian prisoners being carried off by the Assyrians, and £2,500 to the Justice Educational and Research Trust for an inquiry into the investigation of complaints against administrative and executive decisions.

PUBLICATION OF CALORIMETRIC AND THERMODYNAMIC DATA

THE "Resolution on Publication of Calorimetric and Thermodynamic Data", which was adopted by the fifteenth Calorimetry Conference held at Gatlinburg, Tennessee, during September 7–10, 1960, is a revised and extended form of the similar resolution adopted by the eighth Calorimetry Conference held in 1953. It outlines minimum publication standards for the guidance of authors, editors and referees of articles on calorimetry, and states the author's first responsibility is to report his results in a form related as closely as possible to the experimentally observed quantities, with enough details of the experiments and auxiliary information to characterize the results completely. Derived or secondary data should never be published without the primary data on which they are based. The auxiliary information should include a complete description of the apparatus and procedures, with details of the reaction vessel or calorimeter, the temperature and time measuring systems, the calibration and sensitivity of the instrument used and the precision and accuracy of the results obtained; the source and method of preparation of the samples studied, together with analyses and criteria of purity; and the values of the units and physical constants used in the calculations.

One section of the resolution deals in some detail with the presentation of results, and gives recommendations for the thermochemical data, thermal data, and calculated thermodynamic functions which should be included in the description of certain important kinds of thermodynamic studies. It is pointed out that graphical or analytical representation of results is sometimes worth while for the convenience of the reader, but such representations seldom are a satisfactory substitute for tabular presentation of accurate experimental results. Where rough measurements made for technical purposes, or measurements on materials of undefined composition or by inferior techniques, are reported, they should be given minimum journal space and the presentation should clearly recognize the lack of reliability of the results.

PROTEIN AND RIBONUCLEIC ACID IN THE GROWTH OF FERN GAMETOPHYTES

IN many Polypodiaceae, the germinating spore yields a filamentous protonema and rhizoid cell, that is, a 'one-dimensional' growth. After a certain time-lapse, the growing protonema begins to divide by longitudinal walls also, thereby yielding a plate-like structure, or 'two-dimensional' system. This leads on to the typical heart-shaped prothallus or gametophyte. Y. Hotta (*Jap. J. Bot.*, 17, 214; 1960) has now contributed new facts about the role of protein and ribonucleic acid in the differentiation of the gametophyte of *Dryopteris erythrosora*.

Estimation of the protein contents during the course of development clearly indicates that whenever the two-dimensional growth takes place, a sharp increase in protein concentration in the cell can be observed, whereas in the course of the primary one-dimensional growth, protein concentration is gradually lowered. The two-dimensional growth can be specifically inhibited by some amino-acid analogues such as ethionine and 5-methyltryptophan, and is converted to the 'artificial' one-dimensional growth.

The same selective interference of the two-dimensional growth is also brought about by 8-azaguanine, the effective inhibitor of the nucleic acid synthesis. This inhibition can be alleviated by adding corresponding amino-acids or guanine, respectively. Regardless of the nature of the effective inhibitors used, the selective inhibition is always accompanied by an immediate cessation of increase in the protein concentration followed by its gradual decrease. The author has also shown that ribonucleic acid from the two-dimensional prothallium possesses a nucleotide composition distinct from that in the one-dimensional growth. Ribonucleic acid found in the latter, induced artificially by 8-azaguanine, has been shown to have practically the same nucleotide composition as that of the primary one-dimensional growth. Accordingly, it has been tentatively inferred that a special ribonucleic acid fraction which is sensitive to the action of 8-azaguanine is closely related to the two-dimensional growth.

VIBRATIONALLY EXCITED NITRIC OXIDE PRODUCED IN THE FLASH PHOTOLYSIS OF NITROSYL CHLORIDE

By Dr. N. BASCO and Prof. R. G. W. NORRISH, F.R.S.
Department of Physical Chemistry, University of Cambridge

WHENEVER a molecule dissociates by absorbing radiation of shorter wave-length than is required from the known strength of the bond broken, the problem arises of the distribution of the excess energy among the fragments. Frequently it can be shown that one or more of these fragments are produced in an electronically excited state, but, in general, there is some energy which must appear in other forms. For a diatomic molecule, it follows that the atoms are produced with excess kinetic energy, but where a polyatomic molecule is concerned, there is the possibility that one or more of the products are produced vibrationally or rotationally excited in the ground electronic state. The present communication describes what seems to be the only direct experimental evidence that these possibilities are, in fact, realized.

In the flash photolysis of sulphur trioxide, Norrish and Oldershaw[1] observed the presence of vibrationally excited SO with $v'' \leqslant 3$, but, though it was shown that the effect was not thermal, it was not possible to decide whether the excited molecule was produced by primary photodissociation or by secondary reactions, that is:

$$SO_3 + h\nu \rightarrow SO^* + O_2 \qquad (1)$$

or

$$SO_3 + h\nu \rightarrow SO_2 + O(^1D) \qquad (2a)$$

followed by

$$O(^1D) + SO_2 \rightarrow SO^* + O_2 \qquad (2b)$$

Similarly, in the flash photolysis of nitrogen dioxide, Basco and Norrish[2] observed the first vibrationally excited level of nitric oxide, but again it was not possible to decide whether it is a primary or secondary product, in the latter case derived from:

$$O + NO_2 \rightarrow NO^* + O_2 \qquad (3)$$

We have now studied the flash photolysis of nitrosyl chloride in the presence of a great excess of inert gas to ensure isothermal conditions and have demonstrated the presence of very highly vibrationally excited nitric oxide. Many absorption bands in the region 2100–4000 Å. have been observed and it has been possible to assign most of them to transitions from the ground state of NO ($X^2\Pi$) to the $A^2\Sigma$, $B^2\Pi$, $C^2\Pi$ and $D^2\Sigma$ excited states and thus to demonstrate that all vibrational levels of the ground state up to $v'' = 10$ are populated. Some bands remain unassigned or only tentatively so, but it seems likely that these also will be found to correspond to transitions from vibrationally excited levels of the ground electronic state of NO. The decay of the excited molecules is very rapid and those in the higher vibrational levels are only present in appreciable concentrations during the photolytic flash.

Nitrosyl chloride can be decomposed by light of wave-length below about 6400 Å.[3] and, even at this wave-length, there is a slight excess of energy over that required to break the ON—Cl bond. Its extinction coefficient in the ultra-violet below 3350 Å. increases towards a maximum at around 1970 Å.[4] and, under the conditions obtaining in the experiments reported here, most of the absorption occurs in the region below approximately 2700 Å. Assuming the transmission of the quartz flash-lamp and the reaction vessel is negligible below about 1950 Å. the excess energy available lies between about 70 kcal. and 110 kcal. It is now evident from our spectra that at least 50 kcal. of this excess energy can appear as vibrational energy of the nitric oxide molecule and we suggest that it is in the primary process :

$$\mathrm{NOCl} + h\nu \rightarrow \mathrm{NO}^* + \mathrm{Cl} \qquad (4)$$

that this occurs.

The possibility that the NO is initially produced in an electronically excited state from which it enters vibrationally excited levels of the ground state has also been considered. This seems unlikely as there is no known electronic state of NO which, on spin conservation and energetic grounds, could qualify. Experiments designed to set an upper energy limit for this hypothetical electronic state are in progress, with particular reference to the $^4\Pi$ state predicted by Mulliken[5] to lie 4·5 eV. above the ground state.

It is also theoretically possible that NO produced initially without excitation could be excited by the flash. In the flash photolysis of NO this excitation has been realized[6], but it was shown that the reaction :

$$\mathrm{NO}\,^2\Pi(v = 0) + h\nu \rightarrow \mathrm{NO}\,^2\Sigma(v = 0, 1) \qquad (5)$$

followed by

$$\mathrm{NO}\,^2\Sigma(v = 0, 1) + M \rightarrow \mathrm{NO}\,^2\Pi(v = 0, 1, 2 \ldots) \qquad (6a)$$

or

$$\mathrm{NO}\,^2\Sigma(v = 0, 1) \rightarrow \mathrm{NO}\,^2\Pi(v = 0, 1, 2 \ldots) + h\nu \qquad (6b)$$

only produces an appreciable concentration of the first excited level, with the second only just detectable under favourable conditions. It follows that this mechanism can be excluded.

Two other reactions, namely :

$$\mathrm{NOCl} + \mathrm{Cl} \rightarrow \mathrm{NO}^* + \mathrm{Cl}_2 \qquad (7)$$

and

$$2\mathrm{Cl} + \mathrm{NO} \rightarrow \mathrm{NO}^* + \mathrm{Cl}_2 \qquad (8)$$

can be excluded by virtue of the fact that, when chlorine was photolysed in the presence of NOCl using a 'Pyrex' glass filter virtually to exclude the direct photolysis of NOCl, NO* was not observed. For the higher levels, the former can also be excluded on energetic grounds.

There is convincing evidence[1,7,8] that in exothermic reactions of the type :

$$A + BCD \rightarrow AB + CD \qquad (9)$$

up to 100 per cent of the energy liberated can appear as vibrational energy of the newly formed molecule *AB*. Reactions (2*b*) and (3) have provided the only indication so far that the molecule *CD* may be vibrationally excited to some extent ; but the fact that reaction (7) does not produce a detectable concentration of NO* militates against this. As there is no evidence for the presence of Cl_2^* here or for O_2^* being produced in reaction (2*b*), the question remains open.

If it be admitted that the primary process is :

$$\mathrm{NOCl} + h\nu \rightarrow \mathrm{NOCl}^* \qquad (10)$$

rather than direct photodissociation, two other possibilities exist, namely :

$$\mathrm{NOCl}^* + \mathrm{NOCl} \rightarrow \mathrm{NO}^* + \mathrm{NO} + \mathrm{Cl}_2 \qquad (11)$$

and

$$\mathrm{NOCl}^* + \mathrm{NO} \rightarrow \mathrm{NO}^* + \mathrm{NOCl} \qquad (12)$$

Reaction (10) was proposed by Kistiakowsky[3] for decomposition at longer wave-lengths on the grounds that the absorption spectrum showed bands with line structure and that decomposition of NOCl could be achieved by light below 6400 Å., whereas the heat of dissociation (taken as 46·4 kcal.) corresponded to light below 6130 Å. The latter reason is invalid if the value of 37–38 kcal. is taken for the NO—Cl bond[9,10] and, as both he and Allmand[11] pointed out, the fact that the quantum yield of 2 for photolytic decomposition of NOCl is not reduced by a seven-fold dilution with nitrogen or a nine-fold reduction in pressure indicates primary dissociation. At the shorter wave-lengths this would appear to be even more likely. In the present work the excess of nitrogen as coolant over nitrosyl chloride and the pressure of nitrosyl chloride itself have each been varied by a factor of more than 100 without producing any fundamental change in the results obtained. It has also been shown that addition of small quantities of NO to NOCl produces no major effects. Larger quantities decrease the population of the higher levels, though they seem to increase that of the lowest excited level probably because of the reactions :

$$\mathrm{NO}(v = n) + \mathrm{NO}(v = 0) \rightarrow \mathrm{NO}(v = n - 1) + \mathrm{NO}(v = 1) \qquad (13)$$

To summarize, it appears likely that only reaction (4) could reasonably be expected to produce vibrationally excited NO in the yields obtained. The question arises as to the generality of this reaction ; but at least it can be said that the present evidence lends plausibility to reaction (1) and the corresponding reaction with NO_2. In the production of O_2^* by the flash photolysis of ozone[12], the evidence for the mechanism :

$$\mathrm{O}_3 + h\nu \rightarrow \mathrm{O}_2 + \mathrm{O}(^1D) \qquad (14)$$

and

$$\mathrm{O}(^1D) + \mathrm{O}_3 \rightarrow \mathrm{O}_2^* + \mathrm{O}_2 \qquad (15)$$

is convincing, though the possibility of a contribution from the reaction :

$$\mathrm{O}_3 + h\nu \rightarrow \mathrm{O}_2^* + \mathrm{O} \qquad (16)$$

cannot now be excluded.

In preliminary experiments it was found that mixtures of nitric oxide and bromine, on standing for a short while, develop a continuous absorption spectrum in the ultra-violet which may reasonably be attributed to NOBr. Results generally similar to those with NOCl were obtained on flashing this mixture.

IN VITRO TRANSFORMATION OF NORMAL CELLS BY POLYOMA VIRUS

By DR. LEO SACHS and DAN MEDINA
Weizmann Institute of Science, Rehovoth, Israel

THE polyoma virus[1] provides favourable material for investigating the relationship between the lytic and the non-lytic interaction of a virus with animal cells, and for studying the cellular transformation which results in the development of tumours. A necessary requirement for such studies is the establishment of *in vitro* systems of analysis. It has been shown, in an *in vitro* system, that the lytic interaction of polyoma resembles that of some other viruses that do not produce tumours[2]; and it was further found that after *in vitro* infection of normal mouse embryo cultures it is possible to establish a line of cells with a stable cell-virus association[3]. The present experiments were undertaken in order to determine the consequences of infection of mouse kidney cells, and to develop for rat and hamster cells an *in vitro* system for the non-lytic transformation that results in the development of tumours. Rat and hamster tumours are rapidly produced by polyoma *in vivo*[4], and *in vitro* infection of normal embryo and kidney cells of these species showed no obvious cytopathic effect under conditions that produced a clear cytopathic effect on normal mouse cells.

Kidneys were used for the mouse experiments, since cells from this organ are very susceptible to tumour induction *in vivo*. In the first experiments, cultures were made of trypsin-dispersed kidney cells from 12-day-old mice that had been inoculated subcutaneously with polyoma virus *in vivo* when 2 days old. The cultures were seeded with 2×10^6 cells in 50-mm. Petri dishes with 4 ml. of medium consisting of 0·5 per cent lactalbumin hydrolysate in Earle's saline (*LA*-medium) and 10 per cent horse serum. The entire medium was charged every 2 or 3 days. These cultures formed monolayers, but at 5–6 days after seeding there was a strong cytopathic effect, and there was generally at this time virus with a hæmagglutination titre of 8,092 per ml. in the culture fluid. It was also found at this time that, in addition to the cytopathic effect, there were groups of proliferating fusiform cells that did not undergo lysis despite the high virus titre in the medium. These cells were therefore presumably resistant to lysis by superinfection, in the same way as cells of the line that had been established from mouse embryo cultures[3].

The proliferating cells in the kidney cultures continued to grow and could form monolayers. But there were always some cells in the population that lysed, so that continued growth was dependent on the balance between cells that lysed and those that continued to divide. There was the same sequence of events in kidney cultures from 4-day-old mice inoculated with virus *in vivo* when 2 days old, and in monolayers of normal kidney cells from 7 to 10-day-old mice infected *in vitro* at a virus to cell ratio of 10 plaque-forming units per cell. The initial number of proliferating cells from mouse kidney cultures infected *in vitro* was much higher than in comparable experiments with mouse embryo cultures. The existence of proliferation and a lytic response in cells from the same organ has also been observed in organ cultures of mouse salivary glands[5].

Proliferation and lysis were found in all the kidney cultures, which were maintained for 1 month, and even in the line of mouse embryo cells[3] there was still some lysis after more than 1 year *in vitro*. The frequency of lysis seemed to depend on nutritional conditions, and in the mouse embryo line there was, after 1 year, no obvious lysis if the medium was charged daily, but a clear cytopathic effect if there was no change of medium for 3 days. It has been postulated that the non-lytic interaction of polyoma may be associated with the establishment of a provirus[6]. The detection of the non-lytic interaction in the mouse may, however, be complicated by the possibility that there may be a cytopathic effect as the result of lysis due to unstable conditions as in bacterial lysogeny[7], and/or to virus induction. The direct evidence for induction of polyoma virus will be discussed elsewhere (Winocour, E., and Sachs, L., unpublished work).

Kidney and embryo cultures were used for the rat and hamster experiments. Although rat cells could be satisfactorily cultured with *LA*-medium and 10 per cent horse serum, with this medium there was an early degeneration of hamster cultures. However, hamster cells could be grown in Eagle's medium with 4-fold concentration of amino-acids and vitamins (*EM*-medium) and horse serum, and grew even better in *EM*-medium and calf serum. 2×10^6 trypsin-dispersed cells from rat and hamster embryos, and kidneys of 7–9-day-old animals, and from hamster kidneys of adult (2–3 months old) animals were seeded in 50-mm. Petri dishes with 4 ml. of culture medium. The cultures were infected after 2–4 days, at a virus to cell ratio of 1 to 2 plaque-forming units per cell. Virus was adsorbed for 1 or 2 hr., and the possibility of different nutritional requirements for transformation was tested by using different media.

Following the assumption that the non-lytic interaction may be associated with the establishment of a provirus, it was further assumed that there might be another analogy to bacterial lysogeny, in that the frequency of the non-lytic transformation might be increased by the use of lower temperatures during the stages leading to the incorporative interaction[7]. Infected cultures with their controls were therefore also kept for various periods, after the initial seeding, growth and virus adsorption at 37° C., in an incubator with a humidified atmosphere and a constant flow of carbon dioxide in air maintained at 24° C. and then transferred again to an incubator maintained at 37° C.

Some representative results of the rat and hamster experiments are given in Table 1. The results show that non-lytic cellular transformations (as described later) can be obtained in rat and hamster after *in vitro* infection with polyoma virus. The transformations were dependent on the cultural conditions

Table 1. CELL TRANSFORMATIONS AND ACIDITY IN RAT AND HAMSTER CULTURES INFECTED WITH POLYOMA VIRUS *in vitro*

Tissue	Exp. No.	Time at 24° C. (days)	Medium	Morphological transformation observed	Acidity
Rat embryo	126†	0	*EM–HOS*	+	+
	126	0	*EM–CAS*	−	+
	117*	0	*LA–HOS* or *CAS*	−	−
	132*	7	*LA–HOS* or *CAS*	+	+

	122	0	*EM–CAS*	−	+
	122	5	*EM–HOS*	+	+

EM., Eagle's medium with four-fold concentration of amino-acids and vitamins; *LA*, 0·5 per cent lactalbumin hydrolysate in Earle's saline; *HOS*, horse serum; *CAS*, calf serum, 10 per cent serum.

Col. 5: +, transformation; −, no difference observed between infected and control.

Col. 6: +, strong colour difference between infected and control; ±, slight colour difference; −, no colour difference.

* Entire medium changed every 3 or 4 days.

† No change of medium after virus infection.

and the medium used. Thus, for example, with respect to morphological changes, no transformation was observed (exp. 132) in rat embryo cultures with 7 days at 24° C. in *EM*-medium and horse serum, whereas there was a clear transformation under the same cultural conditions with *LA*-medium and horse serum. In the hamster embryos (exp. 131) transformation was observed with calf but not with horse serum, in cultures maintained only at 37° C., whereas transformation with horse serum was found in cultures kept at 24° C. for 8 days after infection. Preliminary experiments on different times at 24° C. indicated that 5–8 days was a suitable time, and transformation was observed in all tissues with the appropriate medium maintained at 24° C. for this period. It also appeared that there was a clearer transformation with a longer time-interval between medium changes. The transformations were observed between 9 and 14 days after infection, and experiments were terminated at 17–26 days.

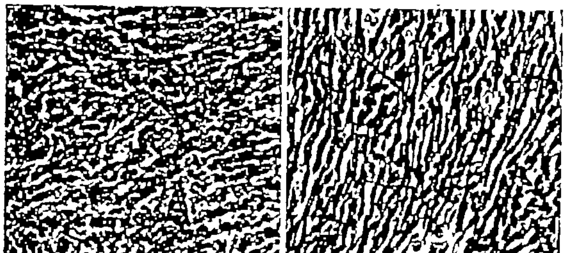

Fig. 1. Control culture of rat embryo cells. Fig. 2. Culture of rat embryo cells with fusiform transformation. Fourteen days after *in vitro* infection with polyoma virus. Methanol fixation, unstained, phase contrast. (× *c*. 112)

In some experiments, in both rat and hamster, there was a regular transformation to fusiform cells (Figs. 1 and 2). In other experiments, with hamsters, fusiform cells tended to form strands with the cells piling up on one another. The difference in appearance of the transformed cultures may have been due to the different conditions under which the cells were grown. The piling-up observed was similar to that produced after *in vitro* infection with Rous sarcoma virus[8]. The transformation by tumour viruses thus presumably includes a loss of contact inhibition[9]. The observation of a transformation is, of course, dependent on a recognizable difference from non-infected control cultures, and in some cases morphological changes may have occurred in infected cells which were not sufficiently different from the controls to be detected readily in the living cultures.

In addition to the morphological changes, there was a difference in the acidity of the medium, in that the transformed cultures were obviously more acid than their controls. There were also some cases (Table 1) of a more acid medium in infected cultures without a morphological difference from the controls. The difference in acidity is presumably due to the changed metabolism of transformed cells. A further difference in both rat and hamster was the better survival of infected cultures under conditions where the controls degenerated. There was also in some experiments a better growth in infected cultures where the controls did not degenerate; and a difference in response to trypsinization. During trypsinization, the cells of controls readily formed cell suspensions, whereas the infected cultures came off the glass either with difficulty and/or in clumps that did not readily disperse.

The above experiments have shown that, in addition to an *in vitro* system for the study of the lytic interaction with polyoma virus, a suitable system is now available for the *in vitro* analysis of the non-lytic interaction associated with cellular transformation. Since the *in vitro* transformations observed include changes in cell morphology, cell metabolism, and what is presumably a loss of contact inhibition, the question arises whether all these changes are required for the malignant transformation. Experiments are therefore now in progress on the growth of the cell cultures in animals.

Note added in proof: Since the above was written, progressive growth has been obtained after inoculation of *in vitro* transformed hamster cells (taken at 14–16 days after *in vitro* infection) into adult hamsters, thus showing that these cells were neoplastic when tested *in vivo*. An independent finding of *in vitro* transformation of hamster embryo cells has also recently been reported[10].

CARBONIC ANHYDRASE AND THE INNER EAR

By Dr. S. D. ERULKAR* and Prof. T. H. MAREN

Department of Pharmacology and Therapeutics, University of Florida College of Medicine, Gainesville, Florida

THE finding of carbonic anhydrase in the ciliary body[1] and in the choroid plexus[2] initiated a long series of experiments involving the activity of this enzyme in the secretion of the aqueous humour and cerebrospinal fluid, and also in the treatment of glaucoma and hydrocephalus[3,4]. We were prompted by results from those experiments to search for carbonic anhydrase in the tissues of the inner ear, and to see what effects the specific inhibitor acetazolamide ('Diamox') might have on the composition of the endolymph.

Seventeen cats, initially anæsthetized with sodium pentobarbital (42 mgm./kgm. intraperitoneally), were used. The middle ear was approached from the ventral side, the bulla was removed and samples of perilymph and endolymph were taken using the approach and technique described by Aldred, Hallpike and Ledoux[5]. In twelve experiments, the fluid was collected by means of capillary tubes; the fluid was then put into small test-tubes and 5-λ samples were taken by ultra-microscopic pipettes. In the remaining experiments the capillary tubes were weighed before the samples were taken, again after sampling, and the volumes were calculated from the weights. After the samples had been taken, the tissues were dissected out under × 40 magnification of the microscope. The apical, middle and basal turns of the cochlea, the vestibule (comprising mainly utricle, saccule, ampullæ and the anterior semicircular canal) and the saccus endolymphaticus, which was approached posteriorly, were all removed and analysed for carbonic anhydrase by the method of Maren, Ash and Bailey[6]. The results of these analyses, compared with those from other tissues in the cat[2], are shown in Table 1. These results, taken with earlier estimations in a variety of tissues[7], gave the surprising result that the tissues of the cochlear partition possess the highest known concentrations of carbonic anhydrase activity of any organ assayed.

There appeared to be a specific distribution of enzyme, with the highest concentrations in the apical turn and saccus endolymphaticus, progressively lower concentrations in the middle and basal turns, and lowest concentrations in the vestibule (Table 1). The striking difference between the carbonic anhydrase concentrations of the cochlea and vestibule deserves comment here. The explanation of the differences may lie in the cytological differences found by Smith[8] in the epithelial cells of the stria vascularis and of the vestibule. Pease[9] showed that organs active in the transfer of fluid are characterized by a great increase in the basal cell surface, and that in kidney tubules, submaxillary gland, choroid plexus, and ciliary body, intensive folding of the basal plasma membrane occurs. All these organs have high concentrations of carbonic anhydrase. Similar structural characteristics have been found to be present by Smith in the utricle[10] and in the stria vascularis and spiral prominence[8]. The stria vascularis, however, is a unique structure in the entire membranous labyrinth. On the other hand, it seems certain that endolymph must be formed and absorbed in the vestibule as well as in the cochlea. Smith[8] suggests that transfer of fluid may be more rapid in the stria vascularis, but also that "the cytological specialization of the marginal cells" of the stria vascularis "suggests some additional process and the question arises whether it may not be also the site of some activity specific to the cochlea". This "cytological specialization" consists of beaded vesicles found in abundance in the basal portions of the marginal cells of the stria vascularis. Palade[11] has observed them in macrophages and suggested that they may be a route for pinocytosis and phagocytosis. One cannot help but speculate that this specialization may be concerned in some way with carbonic anhydrase activity, and that the vesicles may represent sites of concentration of the enzyme.

Control electrolyte data were compiled on plasma, cerebrospinal fluid, perilymph and cochlear endolymph (Table 2). In general these conform closely to the data previously reported by others[12–14]. In confirmation of the work of Smith *et al.*[12], and of Citron and Exley[13], we have found high concentrations of potassium in the endolymph, although this is clearly subject to considerable individual variation. Both these groups have also reported wide ranges of potassium concentration in the cochlear endolymph, but have presumed that the lower values must be artefactual in their origin. The data given by Citron and Exley[13] are presented in Table 3 with their reasons for the values of endolymph potassium. They report that it was the Na^+ and K^+ concentrations *per se* of the endolymph in many samples which suggested contamination with perilymph, and only three samples showed the high values given in the table. In our experiments (Table 3) there are numerous possible reasons for this variation: the difficulty of sampling less than 5λ of fluid, the magnitude of volumetric error, and contamination from perilymph, especially in view of the fact that we do not have any histological sections of this material; it may also be that the potassium concentration of the endolymph is subject to considerable variation physiologically, similarly

Table 1

Tissue	Species	Enzyme units/gm. wet tissue
Choroid plexus (ref. 2)	Cat	262
Kidney (ref. 2)	Cat	275
Ciliary process (ref. 1)	Rabbit	30
Whole blood (ref. 2)	Cat	950
Whole blood (present study)	Cat	943
Inner ear (present study)		
Basal turn	Cat	1,086 ± 314
Basal + middle turns	Cat	1,470
Middle turn	Cat	2,263 ± 556
Apex + middle turn	Cat	2,380
Apex	Cat	3,162 ± 1,180
Saccus endolymphaticus	Cat	3,000
Vestibule	Cat	81 ± 17

Concentration of carbonic anhydrase in inner ear and other tissues. Data obtained from six cats. In two cats, it was impossible to separate middle from basal and apical turns. Only two cats yielded data on the saccus endolymphaticus.

K^+ m*M*/l.	4 3 (6)	4 5 (2)	7·9 (6)	67 (7)	3 6 (8)	3·7 (1)	6 2 (7)	15 (7)

Mean carbon dioxide, chloride and potassium concentrations before and 6–8 hr. after administration of acetazolamide (see text). Numerals in brackets indicate sample number of animals used. For fuller details of potassium concentrations in endolymph see Table 3.

to the potassium concentration of the urine, which is also dependent on a secretory mechanism. It is, however, evident from the data of all workers that potassium is the chief cation of the endolymph, and presumably this unique characteristic reflects the secretory activity of the cells of the cochlear partition. The large variation in K^+ concentration must at present remain unexplained.

Potassium concentration of the perilymph ranged from 6–11 m.equiv. except in one sample, which contained 32 m.equiv.

In six cats, acetazolamide was given intravenously (50 mgm./kgm. as the sodium salt) at zero time and again six hours later, followed by the same dose given intraperitoneally after 12 hr. In some cases pentobarbital anæsthesia was used to facilitate the intravenous injection. 15 hr. following the initial injection of acetazolamide, the dissection procedures described here were carried out. In five experiments, samples were taken from the inner ear of one side in the normal anæsthetized cat. 50 mgm./kgm. acetazolamide was then given intravenously, and 3 hr. later samples were taken from the other ear. Electrolyte and drug concentrations were then determined.

At the time of removal of the samples, the plasma concentrations of acetazolamide ranged from 17 to 65 μgm./ml. The tissues of the inner ear were found to contain drug in the same range, averaging 30 μgm./gm. of tissue or 2×10^{-4} molar. From the values of enzyme units given in Table 1 and the corresponding molar concentrations of enzyme (E) which may be computed from other work in this laboratory[15], it is found that the enzyme concentration in these tissues ranged from about 1 to 6×10^{-5} molar. The K_I of acetazolamide is approximately 1×10^{-8} molar. From these values it may be calculated that the concentrations of acetazolamide found in the tissues are enough to inhibit more than 99·9 per cent of the enzyme originally present.

It was of interest in these experiments that, following the administration of acetazolamide, the volumes and pressures in the perilymph and endolymph appeared considerably reduced, a situation comparable to that reported for cerebrospinal fluid[4] and aqueous humour[1].

Carbon dioxide. The typical renal effect of acetazolamide was elicited, and the animals, at the time the samples were taken, had a definite metabolic acidosis. While untreated cats in the series had average total carbon dioxide values in plasma of 17 m*M*/l., after drug administration the values dropped to 11 m*M*/l. In five normal cats, values for the carbon dioxide of the endolymph ranged from 15 to 21 m*M*/l., and were not significantly different from those of the plasma and cerebrospinal fluid simultaneously sampled.

Table 3

Ref. 13. Cat		
Potassium	117·0 (12)*	

* In many of these samples the sodium and potassium concentrations suggested contaminations with perilymph. Three samples, however, showed the high values for potassium given in the table. The bracketed figure appended to each entry represents the total number of observations on which it is based.

Present study cat		
Controls	9, 20, 51, 55, 85, 123, 127	Av. = 67
15 hr. after acetazolamide	15, 21, 13, 2, 16*, 26†, 10†	Av. = 15

Potassium concentration in cochlear endolymph (m.equiv./l.) of cat.

* 3 hr. cat; † 6 hr. cat.

Chloride. Results for endolymph are preliminary in nature since only six samples were obtained. In two normal samples, the concentration of chloride in the endolymph was higher than that of the perilymph. Our results suggest that following acetazolamide, endolymph chloride decreased, while perilymph chloride may have increased. There does not appear to be any significant change in chloride concentration in either the plasma or the cerebrospinal fluid.

Potassium. Administration of acetazolamide appeared to eliminate all the high values of potassium concentration in the endolymph, and gave average potassium ion values which are strikingly less than the overall values of endolymph reported in our controls and for those of the workers previously cited (Table 3).

Perilymph potassium concentrations following the drug (Table 2) were in the same range as those from control animals. In the few cases studied, the values for cerebrospinal fluid were in the normal range.

These results suggest that carbonic anhydrase may play an important part in the mechanism of active secretion of potassium into the endolymph, and possibly in the overall formation of this fluid. In view of current theories regarding the etiology of Ménière's disease as a 'hydrops' of the inner ear, the obvious analogy to hydrocephalus and glaucoma suggests a rational basis for a controlled trial of acetazolamide for this syndrome.

This investigation was aided by a research grant (*B*-2242) from the U.S. Public Health Service.

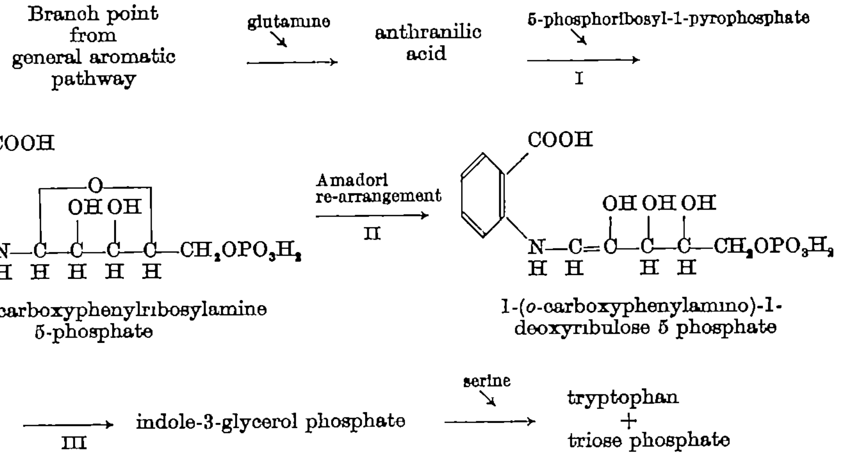
LABILITY OF N-*o*-CARBOXYPHENYLRIBOSYLAMINE AS A FACTOR IN THE STUDY OF TRYPTOPHAN BIOSYNTHESIS

By DR. COLIN H. DOY*

School of Bacteriology, University of Melbourne

INVESTIGATIONS with both whole cells[1] and cell extracts[2] have established 1-(*o*-carboxyphenylamino)-1-deoxyribulose 5-phosphate as an intermediate in tryptophan biosynthesis. The likely sequence of reactions is:



Branch point from general aromatic pathway
glutamine
anthranilic acid
5-phosphoribosyl-1-pyrophosphate
I
COOH
O
OH OH
N—C—C—C—C—CH₂OPO₃H₂
H H H H H
N-o-carboxyphenylribosylamine 5-phosphate
Amadori re-arrangement
II
COOH
OH OH OH
N—C=C—C—C—CH₂OPO₃H₂
H H H H
1-(o-carboxyphenylamino)-1-deoxyribulose 5 phosphate
III
indole-3-glycerol phosphate
serine
tryptophan
+
triose phosphate

The relation of anthranilic acid to tryptophan biosynthesis has recently been discussed in some detail[3]. Mutants blocked in reaction II would normally be expected to excrete N-*o*-carboxyphenylribosylamine (the dephosphorylated form of the postulated intermediate), but preliminary data based on the Bratton and Marshall[4] colour reaction suggested that spontaneous hydrolysis would result in the accumulation of large quantities of anthranilic acid. In this event such mutants would appear to be blocked in reaction I.

Since the Bratton and Marshall method requires the use of acid conditions which could favour the formation of artefact anthranilic acid, the lability factor was re-examined by a new method not requiring the manipulation of *p*H.

In Fig. 1 the ultra-violet absorption spectrum of anthranilic acid is compared with that of N-*o*-carboxyphenylribosylamine under equivalent conditions in a typical biological medium. Since the differential at 247 mμ is present over the *p*H range 6·0–9·0, this was used to follow the reaction: N-*o*-carboxyphenylribosylamine $\xrightarrow{H^+}$ anthranilic acid without the necessity of adjusting the *p*H of experimental samples. The general method was as follows. A 0·005 *M* solution of N-*o*-carboxyphenylribosylamine (or other anthranilic acid glycosylamine) was prepared in 0·05 *M tris* buffer, *p*H 9·0. A 1-ml. portion of this solution was added to 49 ml. of experimental buffer (for experiments at 37° this was pre-heated) to give a final glycosylamine concentration of 0·0001 *M*. The zero-time sample was withdrawn immediately and the bulk of solution placed in a water-bath at the experimental temperature. Further samples were withdrawn as required. The absorbance of all samples was read at 247 mμ (ultra-violet spectrophotometer) without delay.

For the *p*H range 6·0–7·0 the experimental buffer was Davis minimal medium[5] adjusted when necessary with potassium dihydrogen phosphate; in the range *p*H 7·5–9·0 the buffer was 0·1 *M tris*.

At 100 per cent conversion to anthranilic acid there was excellent agreement with the known overall ultra-violet absorption of anthranilic acid (Fig. 1), while at intermediate stages the spectra were consistent with the appropriate mixture of anthranilic acid and glycosylamine derivative.

As shown in Table 1, the half-life of N-*o*-carboxyphenylribosylamine is dependent on *p*H. Media used in accumulation studies with tryptophan auxotrophs are rarely buffered at *p*H-levels greater than 8. Unless special precautions are taken, the buffer is broken and it is not uncommon for the *p*H to fall to between 5 and 6. Even without this drop the

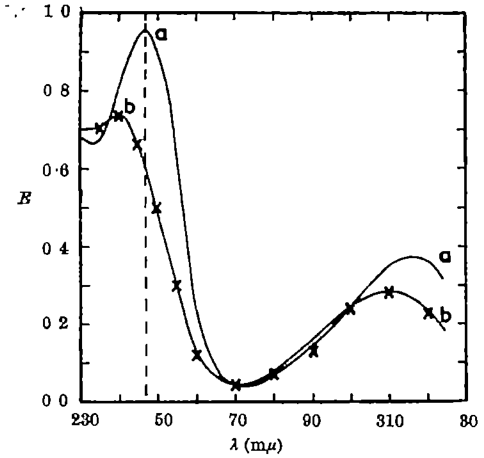

Fig. 1. Absorption spectra of: (*a*) N-*o*-carboxyphenyl-D-ribosylamine; (*b*) anthranilic acid, both 0·0001 *M* in Davis minimal medium, *p*H 7·0. The analytical method for anthranilic acid in the presence of its glycosylamine derivatives depends on the differential at 247 mμ. This differential is essentially the same between *p*H 6 and *p*H 9. ×, absorption of (*a*) at 100 per cent hydrolysis to anthranilic acid determined by E_{247} mμ

chemistry of the situation confirms that strains blocked in biosynthetic reaction II would form large quantities of anthranilic acid, a characteristic expected of strains blocked in reaction I. Strains blocked in reaction III are often referred to as anthranilic acid-accumulating strains. While mutants of this class do form anthranilic acid, appropriate examination of supernatants leaves no doubt that the Amadori derivative is the major product. In the case of mutants blocked in reactions I or II, anthranilic acid would appear as the major product of both types. Various experiments with whole cells[3] have not clarified the problem beyond a slight suggestion that mutants of type II might exist. It seems clear that whole cells are unsuitable for these investigations, principally because there is likely to be a permeability barrier to the phosphorylated glycosylamine. At the cell-free level the situation can be rationalized once the lability factor is taken into account. If both anthranilic acid and N-*o*-carboxyphenylribosylamine 5-phosphate are normal obligate intermediates, it is likely that tryptophan auxotrophs known to form anthranilic acid (in the strict sense discussed above) will eventually be shown to consist of two classes: (*a*) a class able to condense anthranilic acid with 5-phosphoribosyl-1-pyrophosphate; (*b*) a class deficient in this respect. It is also possible that the Amadori re-arrangement step is non-enzymatic.

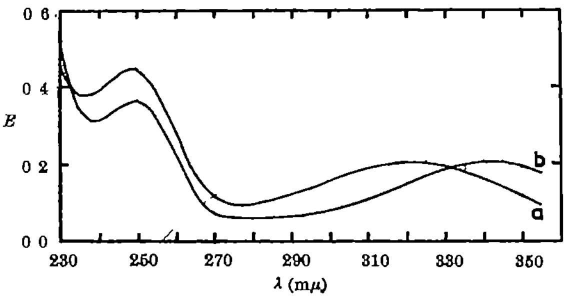

Fig. 2. Absorption spectra of crude 1-(*o*-carboxyphenylamino)-1-deoxy-D-ribulose 5-phosphate. (*a*) 0·0001 *M* in buffer *p*H 7·0 (potassium phosphates 0·1 *M*); (*b*) *p*H adjusted to < 2 with conc. hydrochloric acid

With cell extracts the lability factor to be considered is that of N-*o*-carboxyphenylribosylamine 5-phosphate, not that of the dephosphorylated artefact. The phosphorylated version has yet to be synthesized and is therefore not available for study. Unsuccessful syntheses (Doy, C. H., and Doy, F. A., unpublished) based on successful methods for the nonphosphorylated glycosylamines of anthranilic acid[1] suggest that the phosphorylated form is more labile. A dividend from this work was the isolation of a crystalline compound with properties expected for the phosphorylated Amadori intermediate, 1-(*o*-carboxyphenylamino)-1-deoxyribulose 5-phosphate. Although Doy and Gibson[1] and Smith and Yanofsky[2] have described preparations of the non-phosphorylated and phosphorylated Amadori compound, a crystalline product has not been isolated previously. The present product has yet to be completely characterized, but its ultra-violet absorption at 10^{-4} *M* (Fig. 2) has the expected characteristics. On the basis of previous work, the extinction is of the order predicted. In contrast, Smith and Yanofsky[2] describe similar absorption, but at 10^{-3} *M*. The present measurement is based on weighings calculated from the formula $HOOC.C_6H_4.NH.CH_2.CO.(CHOH)_2.CH_2OPO_3Na_2$, while Smith and Yanofsky[2] base their spectrum on a concentration determined by enzymatic conversion to indoleglycerol phosphate. Since concentration based on weighing is more direct and impurity would be expected to shift maxima or depress extinction, the enzymatic data seems in some doubt.

The purely chemical observations suggest that N-*o*-carboxyphenylribosylamine 5-phosphate is (*a*) more easily hydrolysed to anthranilic acid than the non-phosphorylated form, and (*b*) easily converted to the Amadori compound. The first point would re-emphasize the lability factor in cell-free studies, and the second the possibility that the Amadori re-arrangement is non-enzymatic.

Since manipulations can be reduced to the minimum, fluorescence seems to be the most suitable means of looking for reaction I with cell-free systems. Methods which require the precipitation of protein with trichloracetic acid, or extraction procedures at acid *p*H, ignore the lability factor.

Smith and Yanofsky[2] have applied fluorometry to cell-free studies with anthranilic acid-accumulating tryptophan auxotrophs. Excluding those that were blocked immediately after the Amadori compound (Tryp-3*a* mutants), the remainder (Tryp-3*b* mutants) were classed as blocked immediately after anthranilic acid on the basis of failure to metabolize anthranilic acid. Since the reference describing the fluorometric method requires samples to be transferred to *p*H 6·0, it is possible that the lability factor has obscured the metabolism of anthranilic acid to its ribosylamine 5-phosphate. Similarly, experiments with radioactive substrates do not exclude the possibility of hydrolysis following enzymatic synthesis.

It is not clear whether 'mixing experiments' were done within the Tryp-3*b* class. If individual mutants within this class were point mutations lacking in one instance the enzyme necessary for reaction I and in another the enzyme necessary for reaction II, they would be expected to complement each other in the way described[2] for extract mixtures of Tryp-3*a* and Tryp-3*b* mutants. Such complementation would suggest a subdivision within class Tryp-3*b* mutants without the need to measure N-*o*-carboxyphenylribosylamine 5-phosphate directly.

If experiments can be designed which adequately account for glycosylamine lability, it should be possible to decide finally the question of whether some, all, or none of the anthranilic acid-accumulating strains are blocked in the Amadori re-arrangement step. It will then be easier to decide whether anthranilic acid has the status of a normal obligate intermediate.

This work was for the most part completed in the Bacteriology School, University of Melbourne, and supported by the Australian National Health and Medical Research Council. Work at Harvard was supported by a Fulbright Research Fellowship and a Commonwealth Scientific and Industrial Research Organization Overseas Post-Graduate award.

Note added in proof. Enzymatic results have now been obtained which are consistent with the division of anthranilic acid-accumulating mutants into a group blocked in reaction I and a group blocked in reaction II (Doy, C. H., Rivera, A., and Srinivasan, P. R., *Biochem. Biophys. Res. Comm.*, in the press).

LOCATION OF THE NON-LINEARITY IN HORIZONTAL CELL RESPONSE TO RETINAL ILLUMINATION

By Drs. RICHARD FATEHCHAND, GUNNAR SVAETICHIN, GENYO MITARAI and JORGE VILLEGAS

Instituto Venezolano de Investigaciones Cientificas, Caracas, Venezuela

IN 1953, Svaetichin[1], using micropipette electrodes, found graded responses to light stimuli in isolated fish retinæ. Starting from a negative membrane potential of 10–50 mV., a graded hyperpolarizing signal, termed the 'luminosity response', could be obtained. The relationship between response and light intensity was found to be non-linear. As will be shown, it would appear that the receptor process is linear, and that the non-linearity is probably located in the region of a horizontal cell.

In recent work[2], we have definitely localized the site of origin of the luminosity response by the use of a marking technique[3] and subsequent histological examination. The response was found to originate in horizontal cells located in the bipolar cell layer of the retina. These cells are comparatively large, about 100μ across, and of quite low resistance (probably less than 100 kΩ (ref. 4)). On the basis of ultrastructural studies[5], these horizontal cells are considered to be glia, non-neuronal structures which are apparently much more permeable to sodium than to potassium[6]. Further, retinal tissue contains roughly equal amounts of sodium and potassium[7], neurons and glia are closely packed[5] (100-Å. spacing), and the 'extraneuronal' space is probably about equal to the neuronal space[6]. It is therefore likely that in glia cells the concentration of sodium must be considerably greater than that of potassium.

The non-linearity in horizontal cell response can be exhibited in two ways. Svaetichin *et al.*[8] showed that if the illumination per unit area is kept constant, but the illuminated area increased, the response increased with the number of cones thus illuminated, as shown in Fig. 1. It will be noticed that if the number of cones is not too small, the response increases as the logarithm of the number of cones. If the illuminated area remains constant, but the light intensity is increased, the response increases as the logarithm of the light intensity, provided the illumination is not too low. This is shown in Fig. 2. In this case a large number of cones were illuminated.

The fact that the curves in Figs. 1 and 2 have similar semi-logarithmic forms is explained by the following experimental result: The retina is illuminated by two light spots of the same diameter and of equal intensity, in one case overlapping, and in the other case just touching. The ratio of the response with two spots to that with one spot illuminated is found to be the same under both conditions. A typical result for Centropomidae is shown in Fig. 3, each spot illuminating about a hundred cones. In fact, if the two spots are non-overlapping and the effective intensity taken as the sum of the intensities of the

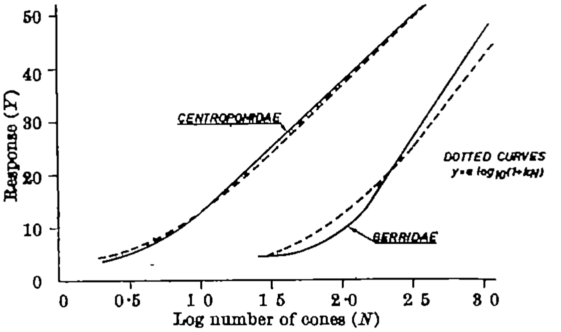

Fig. 1. Horizontal cell response as a function of the number of cones illuminated

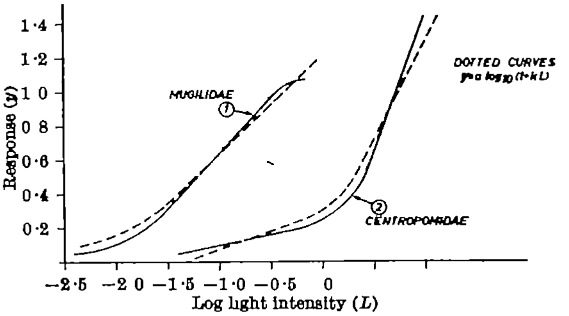

Fig. 2. Horizontal cell response as a function of the retinal illumination. Zero on the horizontal scale corresponds to different light intensity values for curves (1) and (2)

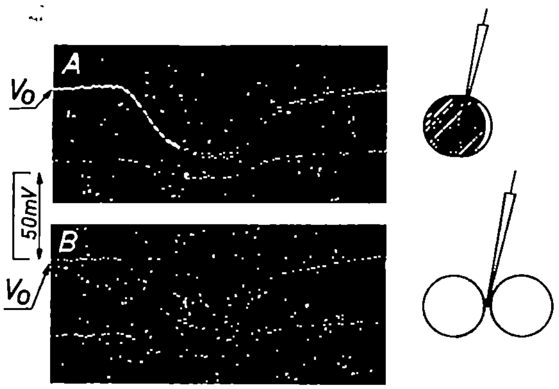

Fig. 3. Luminosity response in Centropomidae, overlapping (A) and adjacent (B) light spots of equal intensity. V_0 is resting potential of the horizontal cell. Duration of light stimulus is 350 msec. Top traces in (A) and (B) show response to single light spot; bottom traces show response with one spot permanently illuminated and the other switched on and off

two spots, the response is similar to the Centropomidae curve in Fig. 2. Hence, since two different groups of cones are involved when the light spots are separated, the non-linearity which affects the horizontal cell response cannot be in the receptors themselves, but must be where their signals converge. This is shown schematically in (A) of Fig. 4. Considering Fig. 1, it now follows that if the number of illuminated cones are increased from N_1 to N_2, with a fixed light flux per cone, the response is that which would be obtained by keeping the number of illuminated cones fixed at N_1 but increasing the illumination in the ratio N_2/N_1. Thus, the curves in Figs. 1 and 2 may be expected to have similar semi-logarithmic shapes, since Fig. 2 was obtained with a fixed light spot diameter.

The physiological system involved is more in accordance with (B) of Fig. 4, since the bipolars which receive signals from the receptors are in close proximity to the horizontal cell the electrical response of which is measured by means of a micro-electrode. It may therefore be expected that the non-linearity is subsequent to the summated actions of the bipolars on the horizontal cell. It is tempting to go further and assume that the horizontal cell potential is associated with a concentration difference of a particular ion i between the inside and the outside of the cell, the 'outside' of the cell being presumably the extremely narrow intercellular spaces of approximately 100 Å. width which are seen in high-resolution electronmicrographs[5]. The resting potential of the horizontal cell is then :

$$V_0 = A \log_{10} \frac{i_0}{i_i} \tag{1}$$

where i_i and i_0 are respectively the inside and the outside concentrations of the ion i, and A is a constant.

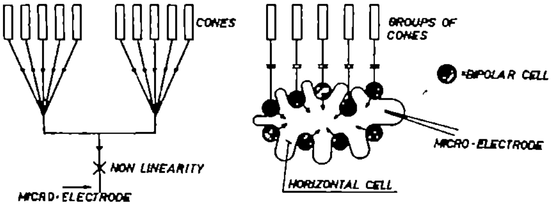

Fig. 4. Location of the non-linearity in horizontal cell response to retinal illumination

We assume that when the cones are illuminated, and equilibrium conditions have been established, a quantity of ions i proportional to the illumination L has passed from the bipolars into the horizontal cell. The horizontal cell potential is therefore increased to :

$$V_L = A \log_{10} \frac{i_0}{i_i + b.L} \tag{2}$$

where b is a constant. It is assumed that the ion concentration i_0 in the 100 Å. intercellular space remains unchanged. Hence, the response to light, as measured by the change in resting potential, is :

$$V_L - V_0 = -A \log_{10}(l + k.L) \tag{3}$$

where k is a constant equal to b/i_i. The dotted curves in Figs. 1 and 2 are of the form given in equation (3), and there is at least a fair fit with the experimental results. However, there is difficulty in accepting this simple interpretation of the source of the non-linearity. The horizontal cell is large, about 100μ diameter, and diffusion of sodium or potassium ions throughout the cell would take a time of the order of 700 msec., using the Hodgkin and Keynes[9] measurements of diffusion-rates in squid axoplasm. But only about 50 msec. elapses between application of illumination and attainment of 80 per cent of the maximum response in the horizontal cell, a time which also includes transmission from the receptors to the bipolar cells (a distance of about 60μ in the fish). Possibly the ionic influx from the bipolars spreads along the cell in some way which involves electric field gradients. It is perhaps significant that if the fish is dark adapted, the luminosity response still follows a similar curve to equation (3); however, the response now has very slow rise and decay phases about 1 sec. (ref. 10), so that this may indicate a diffusion process. In any event, it would certainly appear that the non-linearity in response is closely connected with the horizontal cell; there is, at least, formal correspondence between the response and a hypothetical mechanism which involves the passage of ions between bipolars and the horizontal cell, and the associated change in ionic concentration ratio between the interior and the exterior of the horizontal cell.

Finally, it is interesting that the psychological scale of lightness[11] can be fitted quite well by a relationship of the form of equation (3), while it is well known that in the retina of fishes, etc., there are ganglion cell units where the relationship between spike frequency and illumination is also of a similar form. It is reasonable to suppose that the change of bipolar cell potential in response to light can be represented by equation (3), and that the spike frequency is linearily related to this graded potential as has been shown, for example, by Fuortes[12] in *Limulus*.

FOUR ADULT HÆMOGLOBIN TYPES IN ONE PERSON

By Dr. C. BAGLIONI and Prof. V. M. INGRAM

Division of Biochemistry, Department of Biology, Massachusetts Institute of Technology

THE normal adult type of human hæmoglobin (A) is a single molecular species with the chemical constitution $\alpha_2{}^A\beta_2{}^A$ (ref. 1). Such a molecule contains two identical α polypeptide chains and two identical β chains. It has been shown that the genetically controlled abnormal human hæmoglobins previously examined contain an abnormal α or an abnormal β chain, carrying an amino-acid substitution[2,3]; for example, lysine for glutamic acid in the β chain of hæmoglobin C, $\alpha_2{}^A\beta_2{}^C$ (ref. 4). We wish to report the results of chemical studies on four adult hæmoglobin components[5] found in a single individual, D. K. P.; her hæmoglobins turned out to be normal in both peptide chains, abnormal in one or other chain and abnormal in both chains, respectively. Apart from their genetic interest, these findings allow us to make certain deductions about the mode of assembly of the hæmoglobin molecule.

The blood sample from this patient, D. K. P., became available to us through the kindness of Dr. L. M. Tocantins and Miss J. Atwater of Philadelphia. They have already described[5] the occurrence of four hæmoglobins in approximately equal amounts in this blood, together with their clinical findings. The hæmoglobins are electrophoretically distinct at *p*H 8·6; they have been called[5] hæmoglobins A, G, C and X, which is the order of migration, with A as the fastest component. Electrophoretic comparison with authentic specimens is the basis for naming the first three hæmoglobins; hæmoglobin X was unknown and the slowest hæmoglobin yet described. The hæmoglobin G was found by these authors[5] to behave identically with a specimen of G from Dr. Schneider. It may therefore be identical with the hæmoglobin G of Lehmann and Edington[6] and with the G_{Ib} (for G_{Ibadan}) recently described by Shooter *et al.*[7], and found by them to be abnormal in the α chain. On the other hand, D. K. P.'s hæmoglobin G is different from the G of Schwartz *et al.*[3,8] which carries a substitution of glycine for glutamic acid in the β peptide chain.

The original characterization of hæmoglobins A, G, C and X was done by paper electrophoresis[5]. We have been able to confirm the presence of the four components by starch-gel electrophoresis[9] at *p*H 8·6 in 0·02 *M* veronal buffer (see Fig. 1). The four proteins were also separated by electrophoresis on a starch block[10] in the same buffer. The relative amounts (per cent) recovered were: A, 35; G, 27; C, 23; X, 15.

Each hæmoglobin was digested with trypsin and fingerprinted[11]. Hæmoglobin A appeared to be completely normal (Fig. 2) and hæmoglobin C showed only the expected absence[4] of peptide 4 and its replacement by two new peptides, C-4*a* and C-4*b* (C-4*b* = hæmoglobin C tryptic peptide 4*b*). These peptides were isolated, hydrolysed and their amino-acid content analysed. The results confirmed the glutamic acid to lysine substitution previously reported for hæmoglobin C[4]. It appears, therefore, that D. K. P.'s hæmoglobin C is authentic hæmoglobin C.

Fingerprints[11] of D. K. P.'s hæmoglobin G were more difficult to interpret. The fingerprinting technique had to be modified to make it more sensitive. Isolated peptide bands from paper ionophoresis at *p*H 6·4 are compared side by side by a second ionophoresis on Whatman No. 3*MM* paper in a *p*H 4·7 buffer. It eventually appeared that in hæmoglobin G, two normal peptides—A-3 and A-9—had been replaced by three new peptides. No other changes have so far been detected.

The following relationship for these five peptides was established by means of quantitative amino-acid analyses of the isolated peptides with the Spinco model Moore and Stein automatic analyser, by end-group determinations with the dinitrophenol procedures[12], by stepwise degradation with the Edman–Sjøquist procedure[13] and by fingerprinting[11] of some of the peptides after their digestion with elastase[14].

The hæmoglobin A peptides A-3 and A-9 differ only in that A-9 has an additional N-terminal lysine residue; we may write A-9 = Lys(A-3). The Lys-(A-3) bond in such a peptide would be attacked by trypsin only slowly; hence yields of peptides A-9 and A-3 were found to be variable.

(1) In D. K. P.'s hæmoglobin G, an asparagine residue in peptide A-3 (and A-9) has been replaced by lysine; hence a new trypsin-sensitive bond has appeared which results in the appearance of an additional tryptic peptide. Therefore we can write:

$$\text{A-3} \rightarrow \text{G-3}a + \text{G-3}b$$
$$\text{A-9} \rightarrow \text{G-9}a + \text{G-3}b (= \text{G-9}b).$$

Of course, peptide G-9*a* = Lys-(G-3*a*), as illustrated in Fig. 3.

(2) It so happens that peptide G-3*b* contains methionine, which in the course of fingerprinting is

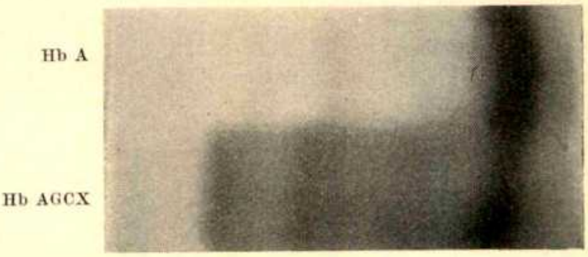

Fig. 1. Starch-gel electrophoresis of D. K. P.'s hæmoglobin at *p*H 8·6 in 0·05 *M* veronal buffer

to some extent oxidized to the sulphoxide. The resultant peptide 'G-3*b* ox' is definitely identifiable, since it is separated in chromatography. Peptides A-3 and A-9 (and for that matter A-25) show the same oxidation phenomenon.

Hæmoglobin X was also digested and fingerprinted[11]. It is clear from the results (Figs. 2 and 3) that hæmoglobin X contains the abnormal peptides characteristic of both hæmoglobin C and G. Peptide A-4 (β chain) is replaced by the two hæmoglobin C peptides C-4*a* and C-4*b*. Peptides A-3 and A-9 (α chain) are replaced by the three hæmoglobin G peptides G-3*a*, G-9*a* and G-3*b*. Hæmoglobin X is therefore a naturally occurring adult hæmoglobin which is abnormal in both its α and its β chains. Such doubly abnormal hæmoglobins have been prepared *in vitro* by Itano and Robinson[15] using dissociation and re-association of suitable mixtures of singly abnormal human hæmoglobins.

One can now write the constitution of D. K. P.'s four hæmoglobins as follows:

Hæmoglobin A = $\alpha_2^A\beta_2^A$

Hæmoglobin G = $\alpha_2^G\beta_2^A$

Hæmoglobin C = $\alpha_2^A\beta_2^C$

Hæmoglobin X = $\alpha_2^G\beta_2^C$

We would deduce from these findings that D. K. P.'s genotype is $\alpha^A/\alpha^G\ \beta^C/\beta^A$ (see also in refs. 16 and 17). It has also been suggested before by Atwater *et al.*[5] that D. K. P. is doubly heterozygous for the G and C abnormalities. Apparently, each gene causes the manufacture of the peptide chain characteristic of it; thus, the α^A gene produces α^A chains, the α^G gene produces α^G chains with lysine in place of asparagine in peptide A-3, and so on. We must next assume that each chain dimerizes as soon as it is formed; $2\alpha^A \rightarrow \alpha_2^A$ and $2\alpha^G \rightarrow \alpha_2^G$. This must be so, since no real hybrids, such as $\alpha^A\alpha^G\beta_2^A$, etc., are produced, although all these chains are present inside the same cells. Finally, the four types of subunit seem to assemble to complete molecules in a random fashion, leading to the four hæmoglobins:

$$\alpha_2^A + \alpha_2^G + \beta_2^A + \beta_2^C \rightarrow$$
$$\alpha_2^A\beta_2^A + \alpha_2^G\beta_2^A +$$
$$\alpha_2^A\beta_2^C + A_2^G\beta_2^C.$$

It is important to realize the random nature of this final step in the assembly of the molecule, in contrast to the previous dimerization step, which is specific. The fact that the four hæmoglobins occur in roughly equal amounts, with A predominating, implies that at least in this patient the rate of manufacture of the different chains is only slightly different. As in the other abnormal human hæmoglobins, the phenotype corresponding to each gene is expressed and the product of all of them is to be found within the same cell.

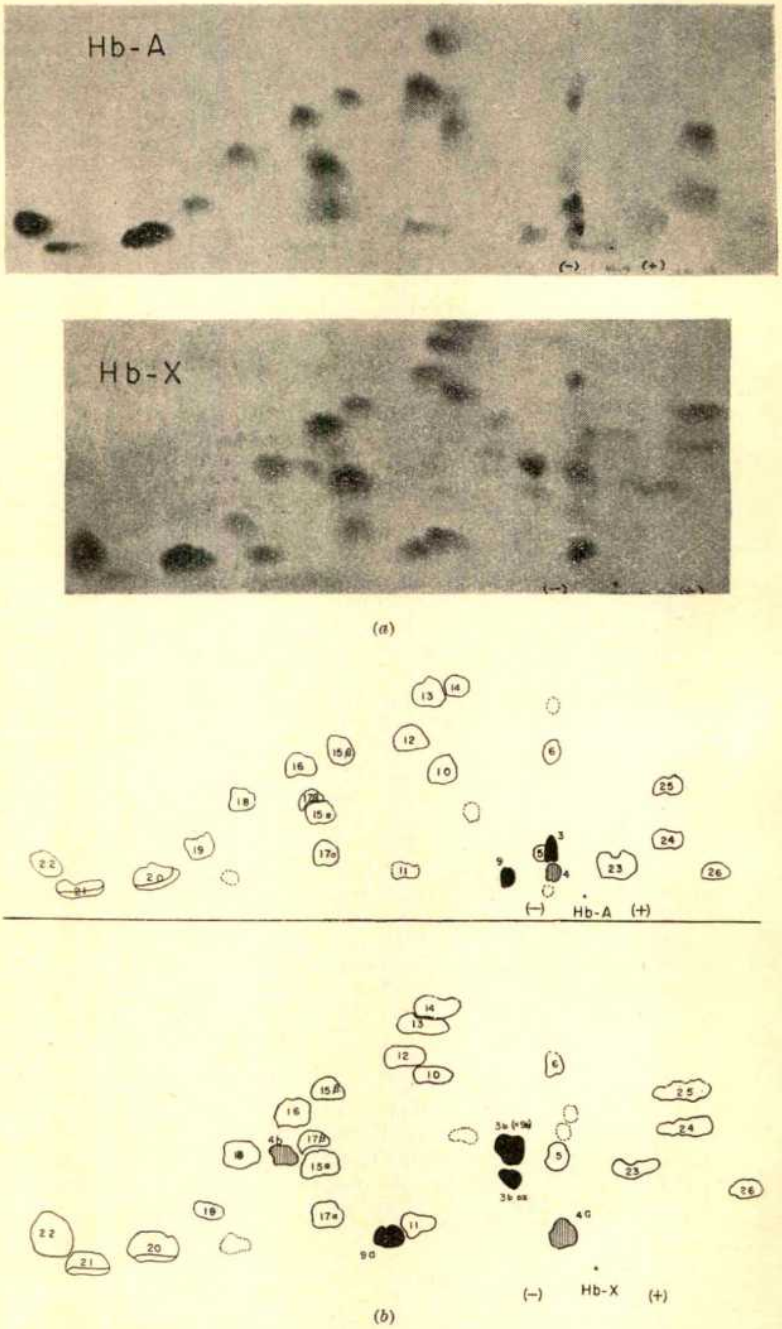

Fig. 2. Photographs (*a*) and tracings (*b*) of fingerprints (ref. 11) of hæmoglobins A and X. Electrophoresis was in the usual buffer but on a cooled brass plate at about 30 V./cm. for 2½ hr. Ascending chromatography is in pyridine : *iso*amyl alcohol : water—35 : 35 : 30 by volume (ref. 18). The methionine residue in G-3*b* is often partially oxidized to the corresponding sulphoxide peptide with a different chromatographic mobility. Such an oxidized peptide is referred to as 'G-3*b* ox'. Peptides A-4, C-4*a* and C-4*b* are marked by a vertical shading. Peptides A-3, G-3*b*, G-3*b* ox and G-9*a* are marked in black

Rather similar chemical results are being obtained by Dr. Park Gerald, Boston, working with an apparently unrelated patient who possesses four hæmoglobins called at present A, D, C and X. However, the four components are not nearly in equal amounts, hæmoglobins C and X greatly predominating. It will be interesting to see whether these hæmoglobins D and X are identical chemically with D. K. P.'s hæmoglobins G and X and why the proportions are so different. Very recently, Raper *et al.*[20] reported briefly on the occurrence of A, G, C, X in one patient, with X abnormal in both chains. The relationship between their hæmoglobins and ours remains to be determined.

Full details of our experiments have been submitted for publication.

We wish to thank Miss Jean Atwater and Dr. L. M. Tocantins for their help and interest. We would also like to acknowledge the help of Miss Marianne Schick, who performed the quantitative amino-acid analysis. This work has been supported by a grant from the Institute for Arthritis and Metabolic Diseases, U.S. Public Health Service.

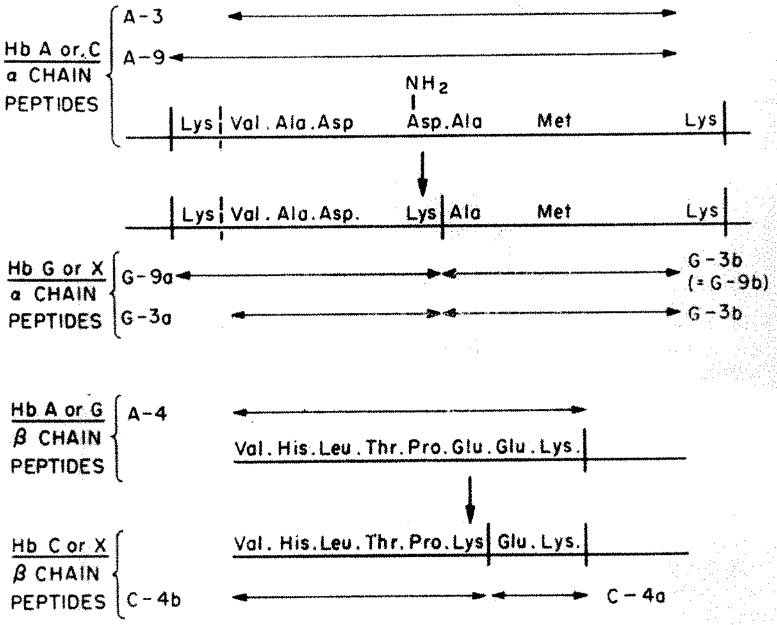

Fig. 3. Diagrammatic representation of the peptides obtained by the action of trypsin on the α- or β-chains of hæmoglobins A, G, C, X. See text for the explanation of the relationship between peptide A-3 and A-9 and between G-3*a* and G-9*a*. In the lower part of the figure it can be seen that peptides A-4 and C-4*b* are at the N-terminus of the β-chains (ref. 19) of hæmoglobins A and C. Peptide A-9 contains 29 amino-acid residues, peptide G-9*a* has 8

GENETIC CONTROL OF FŒTAL AND ADULT HUMAN HÆMOGLOBIN

By Dr. C. BAGLIONI, Prof. V. M. INGRAM and Miss EMELIE SULLIVAN
Division of Biochemistry, Department of Biology, Massachusetts Institute of Technology

ADULT human hæmoglobin (A) is known to consist of two types of polypeptide chain of roughly equal lengths[1]. The gross formula of this hæmoglobin may therefore be written as $\alpha_2\beta_2$, or more specifically as $\alpha_2{}^A\beta_2{}^A$, to indicate that the chains have the amino-acid sequences characteristic of hæmoglobin A. The synthesis of α and β chains is supposedly controlled by separate α and β genes[2]. Fœtal human hæmoglobin (F), on the other hand, has the constitution $\alpha_2{}^A\gamma_2{}^F$, indicating that this hæmoglobin differs in the structure of only two of its four peptide chains[3]. Since Hunt[4] has shown that the α chains of fœtal and adult hæmoglobin are similar, and probably identical, it became of interest to find out whether their production is controlled by the same α chain gene operating in the fœtus and in the adult. The investigations described in this article support the idea of control by the same α chain gene.

Hæmoglobin I was first described by Rucknagel *et al.*[5] as an electrophoretically fast abnormal hæmoglobin. An unrelated case of hæmoglobin I, abnormal in the α chain[6], has more recently been found in a coloured woman, J. W., by Schwartz *et al.*[7]. J. W. is unusual in possessing 70 per cent hæmoglobin I and 30 per cent hæmoglobin A, whereas usually the

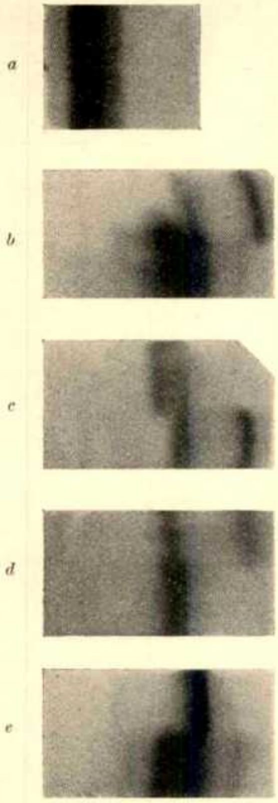

Fig. 1. Starch-gel electrophoresis (ref. 10) experiments in 0·02 *M* veronal buffer, *p*H 8·6. *a*, P. W., cord blood (upper sample) and blood with authentic hæmoglobin Bart's (lower sample); *b*, P. W., 1 day sample (lower) and hæmoglobin A + I from his mother, J. W. Overloaded to show the presence of Bart's in P. W. Note unexplained slow component in P. W., which is not hæmoglobin A_2; *c*, P. W., 2 months sample (upper) and hæmoglobin A + I. Hæmoglobin Bart's has largely disappeared from P. W.; *d*, P. W., 6 months (lower), showing absence of Bart's and fœtal hæmoglobin and hæmoglobins A + I; *e*, P. W., 1 day sample (lower) and 6 months sample

abnormal hæmoglobin comprises less than 50 per cent of the total. Atwater *et al.*[8] suggested that the explanation for this fact lies in J. W. being heterozygous for hæmoglobin I and for thalassæmia. On the basis of a recently developed hypothesis for the occurrence of the thalassæmia[9], we would picture J. W.'s *genotype* as:

$$\frac{\alpha^{I}\ \ \beta^{A}}{\alpha^{Th}\ \beta^{A}}$$

The gene α^{Th} would cause the production of an α chain carrying a type of amino-acid substitution not detectable by electrophoresis, but which nevertheless drastically reduces the rate of production of such chains. Hence would follow the relatively low amount of hæmoglobin 'A'—really $\alpha_2^{Th}\beta_2^{A}$—in the blood of J. W.

Through the courtesy of Dr. L. Tocantins and Miss J. Atwater, we have been able to examine the blood of J. W.'s recently born son, P. W. Examination of the cord blood, and of a specimen collected at 24 hr., by starch-gel electrophoresis[10] at *p*H 8·6 in 0·02 *M* veronal buffer showed the presence of a fast-moving hæmoglobin component, judged to be 10 per cent of the total, in addition to hæmoglobins A and F (Fig. 1). By this method of electrophoresis the fast component had the same mobility as hæmoglobin Bart's[11], a variant of fœtal hæmoglobin, but was considerably slower than J. W.'s hæmoglobin I. The same result was obtained by electrophoresis on a starch block[12] at *p*H 8·6 in 0·05 *M* veronal buffer. The fast component was isolated and dialysed against 0·04 *M* phosphate buffer *p*H 8·0. Its absorption spectrum was normal with peaks at 578, 543, 412 and about 355 mμ, but in the ultra-violet region there was a pronounced tryptophan peak at 291 mμ which is characteristic[13] of fœtal hæmoglobin (Fig. 2). Hæmoglobin Bart's is a fœtal hæmoglobin known[14] to have the constitution γ_4^F and to occur in the presence of thalassæmia[11].

The identity of baby P. W.'s fast hæmoglobin component with hæmoglobin Bart's was further demonstrated by comparing the behaviour of P. W.'s blood with an authentic specimen of hæmoglobin Bart's during ion-exchange chromatography on the carboxyl exchange *CG*50 type II according to Huisman and Prins[15] (Fig. 3). After development of the chromatogram for 30 min., hæmoglobins A and F were clearly separated. Ahead of them moved a well-defined hæmoglobin band at the same speed in the case of P. W.'s blood and in a specimen of hæmoglobin Bart's. Under these conditions, the hæmoglobin I moves between hæmoglobins A and F.

Baby P. W.'s fast hæmoglobin component, isolated by starch-block electrophoresis, was digested with trypsin and fingerprinted[16] alongside hæmoglobins Bart's and F. The pattern of tryptic peptides obtained from hæmoglobin Bart's and P. W.'s fast component showed the virtual absence of peptides 20 (α chain) 18, 9, 13 and 16 (ref. 15). These are characteristic of the α chain of human hæmoglobin. Hence, the fingerprints also suggest that this fast hæmoglobin has the constitution γ_4^F.

Recently, it was found that a precipitate had appeared in P. W.'s 24-hr. sample which had been stored frozen for a few months. At the same time, the fast hæmoglobin component had disappeared from the supernatant, which contained only hæmoglobins A and F. Hæmoglobin Bart's as well as hæmoglobin H (ref. 17)—β_4^A—are known to precipitate very easily. The precipitate from P. W.'s cord blood was fingerprinted by an improved method

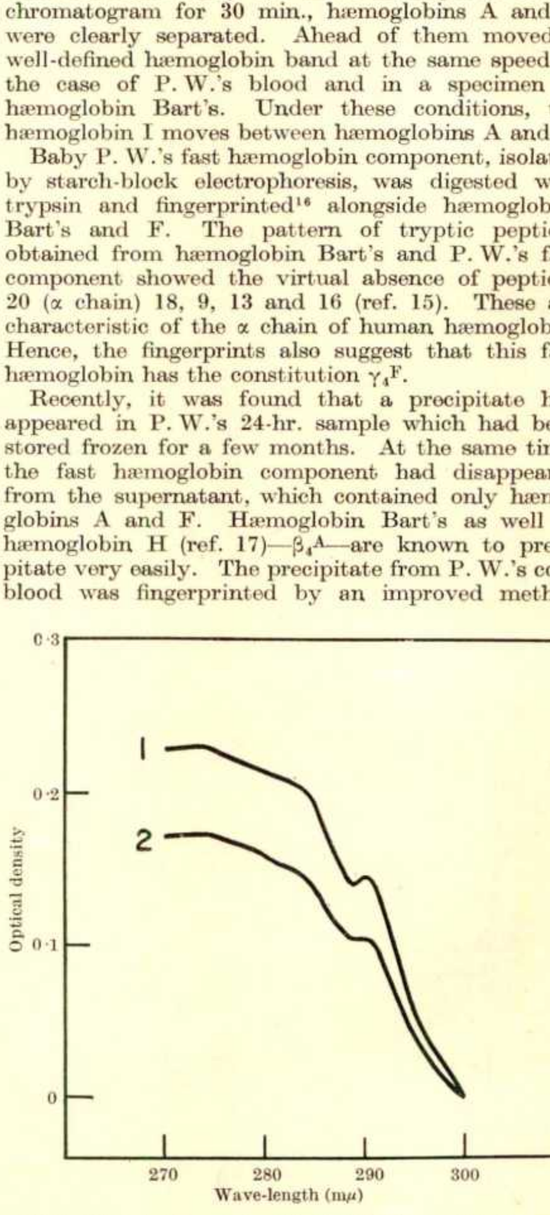

Fig. 2. Ultra-violet spectrum of P. W.'s fast hæmoglobin (1) and of hæmoglobin Bart's (2) isolated by starch-block electrophoresis (ref. 12)

(Fig. 4) and was seen to be largely composed of γ^F chains, as expected for hæmoglobin Bart's.

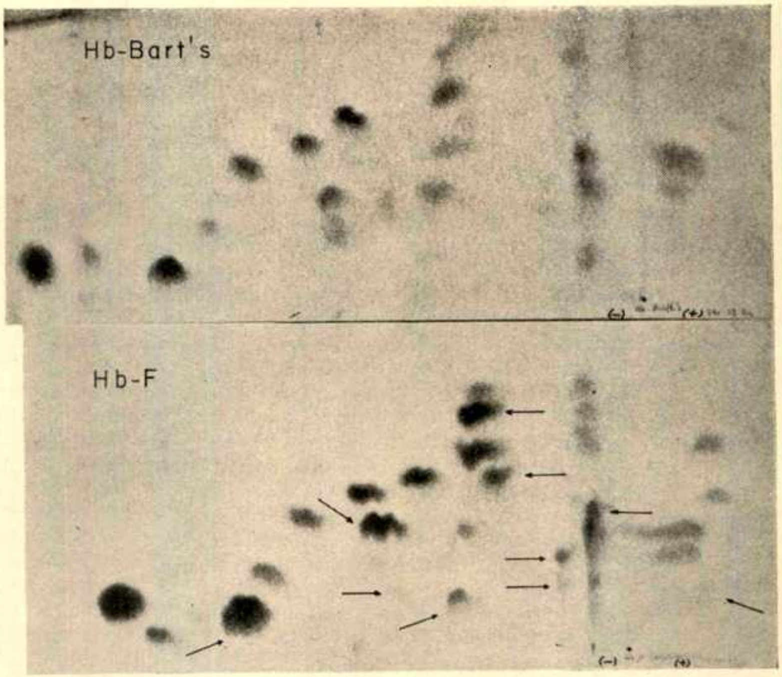

Fig. 4. Photograph of fingerprints (ref. 16) of precipitated hæmoglobin Bart's from baby P. W. and of hæmoglobin F. Electrophoresis was carried out at *p*H 6·4 on a water-cooled brass plate 24 in. long at 30 V./cm. for 2¼ hr. Chromatography was in pyridine : *iso*amyl alcohol : water—35 : 35 : 30 by volume (Wittmann, H. G., personal communication). α-Chain peptides of hæmoglobin F, as indicated by arrows, are largely absent in P. W.'s hæmoglobin Bart's

The fast component in P. W.'s blood had virtually disappeared at six months, as expected for a fœtal hæmoglobin[13].

These results indicated that baby P. W. possesses hæmoglobin Bart's —γ_4^F—but not the hæmoglobin I of his mother. As expected, baby P. W.'s hæmoglobin Bart's had disappeared by 6 months ; but it was not replaced by the corresponding adult hæmoglobin H, which has the constitution β_4^A. Hæmoglobin H, like hæmoglobin Bart's, is usually associated with thalassæmia. Although one might expect *a priori* that the conditions which lead to hæmoglobin Bart's in the baby would also cause the appearance of hæmoglobin H in the adult, this is not necessarily so. Cases have been reported both in favour[18] and against[19] this expectation. The reasons for this variability are not clear.

Baby P. W. showed at 9 months a hypochromic microcytic blood picture[8]. It is reasonable to assume that baby P. W. inherited the α chain thalassæmia gene which is active in his mother, J. W., and which causes a decrease in the production of α peptide chains[9]. In turn, this situation would be expected to lead to an excess of γ chains, or rather γ_2^F dimers, which would then aggregate to form hæmoglobin Bart's. Baby P. W.'s genotype would be :

$$\frac{\alpha^{Th}}{\alpha^{A}}\ \frac{\beta^{A}}{\beta^{A}}$$

The idea that the same α chain is concerned in the production of the adult and the fœtal hæmoglobin is an important one, since it allows us to formulate more clearly the probable mechanism involved in the switch from fœtal to adult protein. It is likely[20] though not undisputed that at the time of birth both hæmoglobins are present within the same cell. In that event, and in view of the findings reported above, we picture the change-over mechanism as involving the switching down of the activity of the γ chain gene and the switching on of the β chain gene, while the α gene remains active all the time.

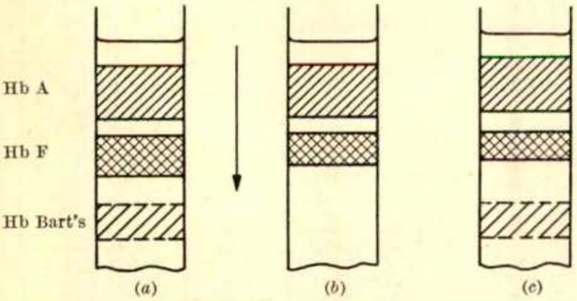

Fig. 3. Column chromatography (ref. 15) of P. W.'s hæmoglobin (*a*), of normal cord blood (*b*) and of blood with authentic hæmoglobin Bart's (*c*)

We wish to thank Dr. L. M. Tocantins and Miss Jean Atwater, Philadelphia, for their encouragement and for their generous help which made this investigation possible. Dr. H. Lehmann, London, generously supplied a sample of hæmoglobin Bart's. We would also like to acknowledge the many stimulating discussions with Dr. Park Gerald, Boston. This work has been supported by grants from the National Science Foundation and from the Institute for Arthritis and Metabolic Diseases, U.S. Public Health Service.

EVIDENCE OF ACTIVE ION TRANSPORT ACROSS LARGE CANINE BLOOD VESSEL WALLS

By PROF. P. N. SAWYER* and I. VALMONT

Department of Surgery and Surgical Research, State University of New York, Downstate Medical Center, Brooklyn, New York

PREVIOUS work by members of this group has shown that disorders of the flow of blood through both large and small blood vessels appear related to induced or spontaneous electrical currents or their related electrical potential differences in either the vessel wall or surrounding tissues[1-3]. Blood cells, including platelets and blood proteins, are cataphoretic in an electrophoretic cell at the *p*H of blood[4-6]. It appears possible that abnormal electric currents produce local positively charged electrophoretic areas or other disturbance of the ionic atmosphere at the blood–intimal interface of damaged vessels; that these positive areas attract negatively charged blood cells to the blood vessel, resulting in intravascular thrombosis[7,8].

A correlated hypothesis suggests that the blood vessel wall under normal conditions expends energy moving ions to maintain the intimal–blood interface potential close to zero in a stable equilibrium. The measured transmural potential difference *in vivo* and *in vitro* appears to be very close to zero[7,8]. Experiments were designed to determine whether evidence for active ion fluxes across the blood vessel wall could be demonstrated.

These investigations were carried out using ion tracer techniques for the study of ion fluxes across membranes evolved by Dr. Hans Ussing[9] and others. Flux cells were modified after Hogben's design[10]. Fresh canine thoracic aorta or vena cava was opened along the long axis and divided into four equal samples of membrane. The segments were placed between four diffusion cell pairs so that each segment of wall formed a membrane 1 cm.² bathed on each side with oxygenated Krebs serum saline substitute[11] at 37° C. Tracer amounts of radioactive isotopes, 1 μc. of sodium-22, or sodium-24, and 1 μc. of chloride-36, were added to the intimal side in two of the cells and to the adventitial side in the remaining two cells to measure the rate of sodium, or chloride flux across the membranized blood vessel wall. One-ml. aliquots of the hourly removed recipient solutions were pipetted, dried and counted in a Geiger–Müller gas-flow counter. Flux was calculated in μmol./cm.²/hr. In selected experiments simultaneous trans-membrane potential differences were determined and compared with the measured ion fluxes across the blood vessel wall *in vitro*.

Ion flux determinations have been made on: (1) fresh, intact aortic wall; (2) aortic wall removed and stored for one or two days in Krebs serum saline substitute at 4° C.; (3) partitioned aortic wall, (*a*) the intima and subintimal layers in one cell compared with the (*b*) media and adventitial layers of the same segment of wall in a separate matching cell; (4) fresh vena cava wall. Only four of many groups studied will be dealt with in this communication.

Attempts were first directed at describing certain physical chemical characteristics of the blood vessel wall. Several groups of experiments resulted. These are: (1) Determination of the cumulative sodium flux across blood vessel wall for periods up to 6 hr. (2) The measurement of net hourly fluxes of sodium and chloride ions across aortic and vena caval wall to measure net ion transport (Fig. 1). (3) Determination of the oxygen dependency of the ion flux mechanisms in various experimental situations. These experiments fall into two groups. In the first group, matching pairs of aortic segments were exposed to ærobic and anærobic conditions (Table 1). In the second group of experiments segments of membranized aortic wall were exposed to sequential 2-hr. ærobic and anærobic periods (Fig. 2). (4) The determination of the temperature dependency of ion flux-rates.

Aorta. Dominant ion fluxes for both sodium and chloride occur from intima to adventitia across fresh, oxygenated, intact aortic wall membrane *in vitro* at a measured transmural potential difference very close to zero (approximate range, 0·3–2 mV.).

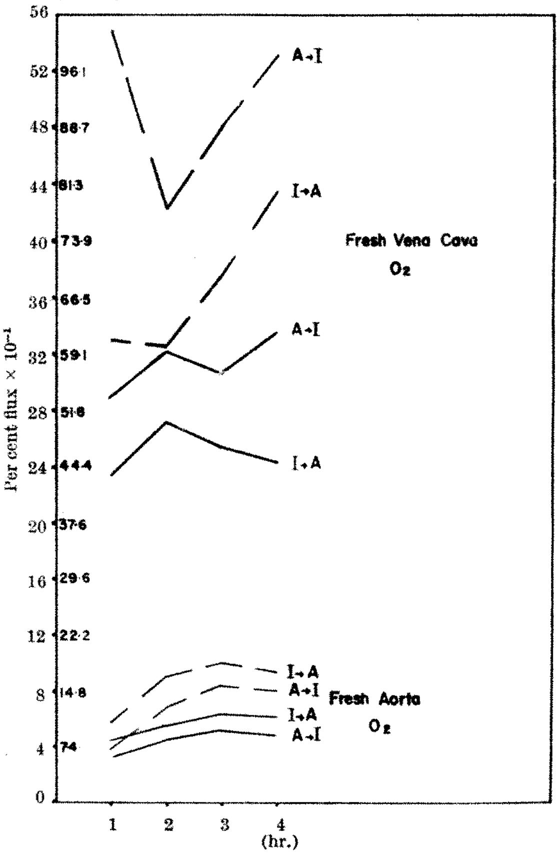

Fig. 1. Difference in rate of ion flux for membranized aortic and vena caval wall. Vena caval flux-rate is 4–5 times aortic flux-rate. *A*→*I* indicates flux from adventitia to intima; *I*→*A*, the reverse; O_2 indicates ærobic conditions. Chloride flux appears dominant for both vena cava and aorta. Vena cava dominant flux *A*→*I*; aortic dominant flux *I*→*A*
– – –, chloride-36; ——, sodium-24

---

* Markle Scholar in Medical Science.

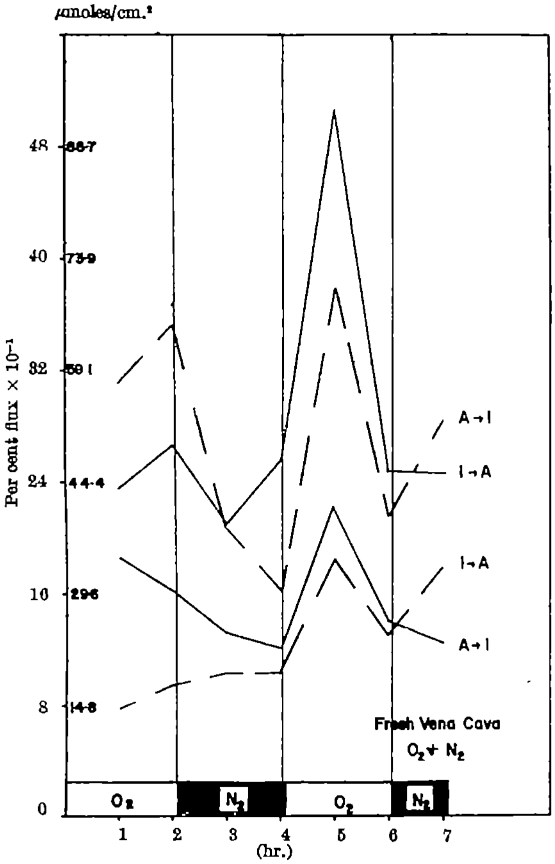

Fig. 2. The effect of consecutive ærobic and anærobic periods on sodium and chloride flux across vena caval wall. Under anærobic conditions sodium flux, $A \rightarrow I$, becomes dominant to chloride flux $I \rightarrow A$ in this experiment. The evidence indicates that sodium and chloride flux across vena caval wall is partially oxygen dependent, as shown for aortic wall in Table 1
– – –, chloride-36 ; ——, sodium-24

Vena cava. Sodium and chloride flux-levels for vena cava are five to six times those for the aorta (Fig. 1). This fact can be explained only in part by the greater thickness of the aortic wall. Both sodium and chloride show a mean net parallel flux. Note, however, that net flux across the aorta occurs in the opposite direction to that across the vena cava.

Ærobic versus anærobic ion transport (*Fig.* 2). In matched experiments in which two samples of membrane were exposed to oxygen and two samples of membrane to nitrogen, net ærobic sodium flux was usually opposite in direction to net anærobic sodium flux. The absolute magnitude of net fluxes was always different in the two groups, being greater under ærobic conditions (Table 1). Sodium and chloride ion fluxes across both aorta and vena cava show at least two types of marked change during sequential ærobic and anærobic periods. An absolute change in flux-rate occurs on switching from ærobic to anærobic conditions. Sodium frequently replaces chloride as the dominant ion transported across vena caval wall on establishment of anærobic conditions (Fig. 2).

Temperature effects. The information from experiments in which cell temperature was raised in steps indicates that the ion flux increases approximately 8–15 per cent per deg. C. rise from 8° to 56° C. The rate of flux increase per deg. C. closely parallels the changing rate of metabolic activity one might expect if sodium and chloride flux occurred across the blood vessel wall as the result of a metabolic process.

An Arrenhius plot of the rates of sodium and chloride ion flux indicates that the absolute rate of flux per deg. C. change varies critically at approximately 25° C. and again at 40° C. (Fig. 3).

Under the conditions of the experiment described, the greater part of ion movement across the blood vessel wall appears to be passive. Proof that all the ion movement is not passive is indicated by evidence presented in this article.

(1) Sodium and chloride fluxes across the membranized blood vessel wall are not identical in each direction.

(2) Net sodium and chloride ion movement across the aortic wall appears to be oxygen-dependent ; net flux frequently reverses onestablishment of anærobic conditions. The flux-rate change per deg. C. change in the temperature experiments and correlated Arrhenius plots also indicates active transport. By definition, both chloride and sodium flux in these

f_i = inward flux, adventitia to intima.
f_0 = outward flux, intima to adventitia.

experiments appear to be active transport, since the blood vessel wall or some of its layers bathed with identical solutions on each side move ions differentially at a measured potential difference close to zero. The results for the experiment for sodium and chloride flux exceed by 5–10 times the fluxes necessary to satisfy Donnan equilibrium equations at 37° C. (Table 2). For any univalent ion:

$$\frac{f_i}{f_0} = \frac{C_i}{C_0 Z}$$

$$C_i = C_0$$

$$\frac{f_0}{f_i} = Z$$

$$Z = \exp(Ef/RT)$$

$$Z_{37^\circ\text{C.}} = 10^{PD/0\cdot61}$$

$$PD = 61 \log Z_{37^\circ\text{C.}}$$

where *E* is potential difference (*PD*) in mV., *f* is Faraday's constant, *R* is gas constant, *T* is absolute temperature, if ion movement across the membrane is passive.

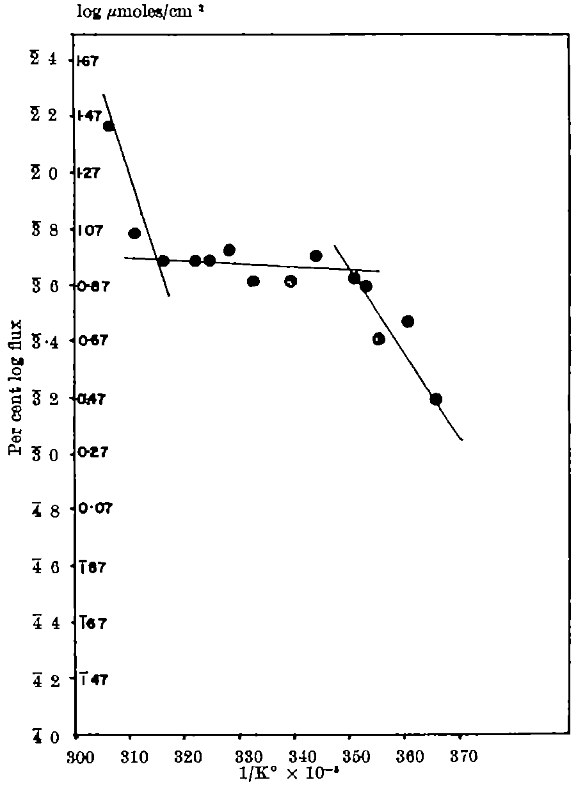

Fig. 3. An Arrhenius plot of sodium-24 flux-rate $I \rightarrow A$ across vena caval wall during which cell temperature was raised from 8° to 65° C. Log per cent flux is plotted to the left of abscissa, log μm./cm.²/hr to the right. The reciprocal of the absolute temperature is plotted on the ordinate

The results indicate that absolute change in flux-rate occurs as certain temperature-levels are reached

Net transport of one ion may occur at a very small transmural potential difference (1–2 mV.) under the conditions of this experiment only if equal amounts of another ion of equal and opposite sign accompany the measured ion across the experimental membrane, or an ion or ions of like or equal charge move in opposite direction across the membrane. Which of the two already-mentioned possibilities pertain to the situation described has still to be ascertained, for several other ions available to the vessel wall membrane could easily be transported during these experiments.

Do those experiments, performed *in vitro*, mirror phenomena which occur in living blood vessels *in vivo*? Evidence is available which indicates that brain capillaries do not fulfil Donnan equilibrium requirements and show evidence of active transport *in vivo*[12]. Whether the experiments described in this article relate to similar phenomena across smaller blood vessels and capillary walls has still to be determined.

Much has been conjectured concerning the fact that aortic and vena caval wall transport in opposite directions. Experiments and theory attempting to explain the difference will be offered in later publications.

Close to the blood intimal interface the net charge due to small net positive or negative ion transport across vessel walls may have a considerable though short-lived effect on interface potential differences. It would appear that tissue injury currents could derange this type of ion transport mechanism if of sufficient magnitude, and might result in reversal of net ion transport as is shown frequently in anaerobic experiments in this work. It is conceivable that vascular occlusion due to spontaneous tissue injury or due to applied small pseudo-injury currents might occur as a result of derangements in the flux mechanisms described here.

We wish to acknowledge the aid given by Dr. Adrian Hogben and Dr. Kenneth C. Cole in the course of these experiments.

The work was supported by grants-in-aid from the National Heart Institute, the National Institutes of Health and the American Heart Association.

GEOPHYSICS

Upper Limit for Interstellar Millicycle Gravitational Radiation

THE effect of gravitational radiation on an elastic body has been previously investigated[1]. The component varying with time of the Riemann tensor (R_{iojo}) associated with the gravitational field acts as a driving term in the wave equation for the strain or displacement. It was proposed[1] that the normal modes of the Earth or a laboratory mass be used as a detector of gravitational radiation. Experiments to measure the interstellar gravitational radiation at kilocycle frequencies are at present in progress at the University of Maryland.

From theoretical arguments we expect the interstellar gravitational radiation noise spectrum to show a peak at very low frequencies. It would therefore be advantageous to use a detector with as low a frequency response as possible. The largest mass available for an experiment is the Earth itself. The various theoretical modes for the vibration of the Earth have been known since 1882. However, it has not been until recently[2] that instruments with sufficiently long period have been available to measure the frequency and amplitude of these modes.

The data used were obtained from the N.32° W. Benioff strain seismograph at Isabella, California. The amplitude of the strain in the Earth's crust has been analysed from these data at the Seismological Laboratory of the California Institute of Technology, with the aid of the computational facilities at the Sandia Corporation[2]. Measurements taken after the recent Chilean earthquake were sufficient to identify the various vibrational modes and determine their breadth and frequency.

The data taken from the Isabella strain gauge during a quiet period do not show peaks at the frequencies of the various vibrational modes, hence the strains observed by the gauge are extraneous strain noise above the level of the actual strains in the modes during a quiet period. The data are therefore only useful for setting an approximate upper limit for the effects of gravitational radiation. Because of this, an exact analysis of the effect of the Riemann tensor on the various vibrational modes, although possible, would be of little value. For the purpose of calculating an upper limit, we shall use the equations obtained by Weber for the magnitude of the strains induced by the Riemann tensor in a longitudinally vibrating rod[1].

The strain in the elastic body at resonance is related to the Riemann tensor by:

$$\varepsilon(\omega) \approx \frac{2c^2 Q}{\omega^2 \pi} R_{iojo}(\omega) \qquad (1)$$

Here $\varepsilon(\omega)$ and $R_{iojo}(\omega)$ are the Fourier transforms of the strain and Riemann tensor, respectively, ω is the angular frequency, c is the speed of light and Q is the ratio of the frequency to the resonance half-intensity width. By squaring equation (1) and integrating over all frequencies, we obtain for the mean squared strain associated with a given mode:

$$\overline{\varepsilon(t)^2} \approx \frac{4c^4 Q}{\pi^2 \omega^3} R^2_{iojo}(\omega) = \frac{60GQ}{c^3 \omega} t_{or}(\omega) \qquad (2)$$

In equation (2), $R^2_{iojo}(\omega)$ is the power spectrum of the Riemann tensor, G is the constant of gravitation and $t_{or}(\omega)$ is the power spectrum of the incident gravitational energy flux, assuming the radiators are at rest relative to the Earth.

The results obtained by the Seismological Laboratory and the upper bound to the Riemann tensor and energy flux power spectra are given in Table 1 for a number of frequencies. The strain data were smoothed since the fluctuations observed were random and not correlated with the modes of the Earth.

Table 1

Fundamental mode	Period (min.)	Q (est.)	Strain² (av.)	$R^2_{iojo}(\omega)$ $\left[\frac{1}{\text{cm.}^4\ (\text{rad./sec.})}\right]$	$t_{or}(\omega)$ $\left[\frac{\text{watts}}{\text{cm.}^2\ (\text{rad./sec.})}\right]$
S_2	54·0	400	80×10^{-25}	$< 0·5 \times 10^{-75}$	< 20
S_4	25·8	350	20	2	20
S_6	16·0	300	8	8	10
S_8	11·81	250	4	5	10
S_{10}	9·66	210	2·5	7	10
S_{14}	7·47	180	1·2	10	10
S_{20}	5·78	160	1	20	10
S_{30}	4·37	120	0·6	30	10
S_{38}	3·66	100	0·6	60	10

This table indicates that the Riemann tensor power spectrum of the incident gravitational radiation cannot be larger than ≈ 10^{-75}/cm.^{4} (rad./sec.) in the vicinity of 1 c./hr. The figures for the energy flux are very high [20 watts/cm.^{2} (rad./sec.)], but not particularly meaningful. The energy associated with a given Riemann tensor depends on the reference frame in which it is defined. We chose the rest frame of the assumed radiator. If we had calculated in a rest frame fixed in the Earth's centre of mass, and averaged over the volume of the Earth, numbers for the energy flux about ten orders less would have been obtained. This is because the Earth is in free fall and the energy flux always vanishes at the pole of a geodesic co-ordinate system. Another assumption is that the Earth is behaving like an elastic body when driven by the Riemann tensor. If the Earth behaved like a liquid, the surface strains would be several orders less for a given Riemann tensor and the limits of the table correspondingly greater.

Earth strain data enable calculation only of the power spectrum of the Riemann tensor. Other effects, such as the fluctuation of the Earth's rotation period, enable the total flux to be estimated[1].

A Maximum of Temperature in the Middle Ionosphere

J. FUCHS[1] has already pointed out the fact that from the change of electron-density (N) with height (h) conclusions as to the temperature in the ionosphere can be drawn. It was, however, not possible then to carry out exact calculations for two reasons: first, the electron-density was only known to be dependent on the apparent height (h'), and secondly, the process of electron loss was not known in more detail, so that Fuchs had to calculate with a recombination-coefficient constant as to space and time.

To-day these two difficulties have been overcome; some institutions have for some time been publishing detailed $N(h)$ profiles, for example, the Central Radio Propagation Laboratory (Boulder) hourly values for the station Puerto Rico. For the process of electron loss, I[2] have introduced the following equation:

$$L = \alpha_0 p^k . T^n . N^{m+2}$$

It has been possible recently to define the constants k and n and this has enabled me to determine from the $N(h)$ profiles the height dependency of scale height (H) and density. The results with regard to the observations of Puerto Rico can be summarized as follows:

(1) The scale height has during the day a maximum at a height of about 200 km. (2) The value of this maximum shows a considerably daily and yearly variation. In the early morning and late afternoon the maximum is much less noticeable than at noon. (3) The height in which this maximum occurs shows a corresponding daily and annual variation: at noon during the summer the maximum of H rests at a height of about 220 km.; it descends to about 180 km. in the morning in winter. (4) Above this maximum the scale height decreases rapidly, and I presume that the gradient dH/dh is getting small only a little below the $F2$ peak. (5) The decrease in density with height corresponds roughly to the result which Priester[3] was able to publish recently.

GEOLOGY

Flow Folding in Rocks

PROF. L. U. DE SITTER[1] considers that in flow folding "internal movement itself is no longer orientated but can take any direction", and that the position of shear planes is random. He believes it developed most typically in incompetent rocks like salt, or at very high confining pressures or high temperatures. It is further maintained that this is the only true plastic deformation of rocks. These beliefs have recently been reiterated and enlarged on[2].

Such views appear to be becoming general, and Ball[3] further characterizes monogenetic folds formed by flow by stating that "the quartz fabric will tend to be markedly heterogeneous, and the symmetry of the fabric will not correspond to the symmetry of the fold".

A brief account of the concepts on plastic flow of rocks will indicate that the current use of the term 'flow' has probably to do with only one type, which is difficult to accept as occurring within rocks.

Flow in rocks is a permanent change of form without apparent rupture, and any fracturing that may occur is microscopic. This property of flow is referred to as plasticity[4]. Above microscopic level such plastic flow is a continuous deformation where neighbouring points in the material remain so during the deformation.

Leith[5] and others have stated that flow takes place by interior readjustments of rock substances by chemical, mineralogical, and mechanical changes. Commonly, the deformation results in a parallel arrangement of the constituents of the rock mass, producing a banded structure, schistosity or cleavage[6]. However, flow may leave no evidence in any parallel arrangement.

Little is known of the mechanics of plastic flow. Nevertheless, possible comparisons between plastic and viscous flow can be made[7], and the mechanics and the successful application of steady, stable, laminar flow to a number of folds have been described in papers by Cloos[8] and Carey[9,10].

Folds that appear to have resulted from a laminar type of flow more or less perpendicular to the rock layers are characterized by thickened and thinned beds, crenulation of bedding planes, and generally a persistence in depth. Where planar discontinuities have developed and folding has progressed by movement along these planes the resulting deformation has been termed a shear fold.

It appears that these laminar-flow folds are excluded from de Sitter's class of flow folds which, because of the postulated random movement, must refer to a mechanism comparable with turbulent viscous flow.

According to reasonable calculations magma is intruded in most dykes by means of laminar flow and turbulence is only achieved in those magmas which have low viscosity due to super-heating or to a high content of volatile material[11]. By analogy it appears most unlikely that a type of turbulent flow can ever be achieved within rocks, which have, in comparison, enormously high viscosities.

It is, therefore, suggested that the folds at present believed to belong to de Sitter's class of flow folds should be reconsidered, and attempts made to interpret them in terms of laminar flow, for not all folds that result from laminar flow may appear geometrically simple. It has been proposed that lateral laminar flow along involuted planes within liquefied layers of sand can account for convolute folding that may occur within them[12]. Is it perhaps possible that the complicated plastic folds with, at first sight, random orientation of the foliations, are in point of fact due to similar unusual patterns of laminar flow?

It appears that the class of flow folds, the present status of which is here questioned, should be redefined to include folds resulting from laminar plastic flow. In so far as all rocks flow during folding, limits must necessarily be rather arbitrary. Competent layers, which retain approximately their original thickness perpendicular to the bedding, show only sufficient flow for them to be flexed. Thus, flexural or concentric folds, and folds of patterns determined by the flexing of competent layers within an interbedded sequence of competent and incompetent horizons would be omitted. Only those folds determined by flow rather than flexure should be included. Flow folds may, therefore, be defined as contortions affecting only incompetent beds, which have thickened and thinned without the aid of ruptures above microscopic levels.

Basutoland Kimberlites

SINCE 1954 a prospecting programme for diamonds in the British Protectorate of Basutoland has led to the discovery of a new predominantly basaltic kimberlite province to the east of the micaceous kimberlite province in the Orange Free State of the Union of South Africa. The kimberlites are intruded into Karroo sediments and lavas and comprise both dykes and diatremes. Petrographically the kimberlites are similar to kimberlites in other parts of South Africa[1,2] and they contain inclusions of eclogite, granulite, peridotite and ilmenite in addition to inclusions of the Karroo country rocks.

Spectrographic analyses of the kimberlites reveal that the trace elements, like the major elements, can be divided into two contrasting suites: (*a*) those in amounts typical of ultrabasic rocks; (*b*) those in amounts typical of alkaline late differentiates. Like the ultrabasic potassic rocks of Uganda which exhibit similar chemical features[3,4], it is believed that kimberlite owes its origin to reaction between a carbonatitic magma and crustal granite. More detailed results are to be published shortly.

PHYSICS

Normal Mode Interpretation of the Sound Propagation in Whispering Galleries

THE propagation of sound in 'whispering galleries'[1] is a very remarkable phenomenon, and in Lord Rayleigh's *Theory of Sound* he gives his well-known interpretation based on observations at St. Paul's Cathedral in London. According to my observation, which agrees with Lord Rayleigh's comment in his book, the opinion of the Astronomer Royal ascribing the phenomenon to the reflexion at the upper dome is hard to accept. This follows because at the diametrically opposite point of the gallery the whisper can scarcely be heard, whereas it becomes stronger as one approaches the speaker.

Lord Rayleigh's explanation is, to use present-day terminology of elastic surface waves, based on 'ray theory'. There is, however, another way of describing so-called 'normal mode theory', and the following analysis based on this theory is in accord with the ray theory interpretation given by Lord Rayleigh.

Adopting the velocity potential ϕ, we have a solution referred to polar co-ordinates R, θ and φ as follows:

$$\phi = ([p/c]R)^{-1/2} J_{n+1/2}([p/c]R) Y_n(\theta,\varphi)\exp(ipt) \quad (1)$$

where p is the frequency, c the velocity of sound, J_ν is the Bessel function and $Y_n(\theta,\varphi)$ the spherical surface harmonics. Assuming that the wall is approximately rigid, the boundary condition, a, being the radius of the gallery, is:

$$\text{at } R = a; \quad \partial\phi/\partial R = 0 \quad (2)$$

which gives an equation of the form:

$$\partial[\xi^{-1/2} J_{n+1/2}(\xi)]/\partial\xi = 0, \; \xi = (p/c)a \quad (3)$$

Since the circumference of the gallery is roughly 100 yards, and the wave-length of the voice is about 1 yard, n is about 100.

Trying the numerical solution for smaller values of n, we find that $n + 1/2 < \xi$. Hence we employ the next form of asymptotic formula for the Bessel function with large orders[2]:

$$J_\nu(\nu\sec\beta) \sim \left(\frac{2}{\pi\nu\tan\beta}\right)^{1/2}\left[\cos Q + \frac{1}{\nu}\cot\beta . \left(\frac{1}{8} + \frac{5}{24}\cot^2\beta\right)\sin Q\right] \quad (4)$$

$$Q = \nu(\tan\beta - \beta) - \pi/4$$

and put it into the above expression. Then we have the characteristic equation:

$$\frac{1}{\nu}\left(\frac{7}{24}\tau^3 + \frac{7}{8}\tau\right) + \left[\frac{1}{\nu^2}\left(\frac{35}{48}\tau^6 + \frac{35}{24}\tau^4 + \frac{9}{8}\tau^2\right) + 1\right] . \tan Q = 0 \quad (5)$$

$$\tau = \cot\beta$$

$$\nu = n + 1/2 \text{ and } \nu\sec\beta = \xi \quad (6)$$

The approximate solution of this equation is obtained assuming that $\nu\beta^3$ tends to a certain value different from zero when ν increases indefinitely, namely:

$$\frac{7}{24}\frac{1}{\nu\beta^3} + \left(\frac{35}{48}\frac{1}{\nu^2\beta^6} + 1\right) . \tan\left(\frac{1}{3}\nu\beta^3 - \frac{\pi}{4}\right) = 0 \quad (7)$$

The root is

$$\nu\beta^3 = 1{\cdot}99 \quad (8)$$

which, combined with (6), gives:

$$\xi = (n + 0{\cdot}5) + 0{\cdot}79(n + 0{\cdot}5)^{1/2} \quad (9)$$

The intensity distribution of ϕ with regard to radial direction is given by the function:

$$\Phi = A . ([R/a] . \xi)^{-1/2} J_{n+1/2}([R/a] . \xi) \quad (10)$$

in which n and ξ are connected by the relation (9). This function can be evaluated by the above asymptotic expansion (4) and other similar formulæ.

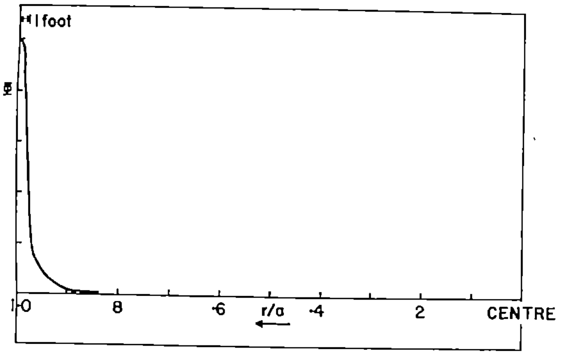

Fig. 1

Assuming $n = 100$, I carried out the numerical computation of the function Φ, in which A was given a value such that the function becomes unity at the surface $R = a$.

The property of the curve given in Fig. 1 agrees well with my auditory observation in St. Paul's Cathedral. If the ear is moved about 10 in. from the wall the intensity of the sound does not change much; but after that it falls off rapidly. Since the circular corridor along the wall is about 6 ft. wide, the observation cannot be continued further than that; but in fact the whisper is scarcely audible at the edge of the corridor.

These characteristics are exactly those of the so-called guided waves. In a homogeneous medium of half-space, sound waves do not give surface waves like Rayleigh waves in a solid. However, if the medium is surrounded by a rigid spherical wall, a kind of guided wave can exist, and this is what is observed in whispering galleries. The surrounding wall is neither exactly spherical nor circular cylindrical in the case of St. Paul's Cathedral; but these calculations give a rough approximation of what takes place in the gallery.

Measurement of Pressure in Vacuum Physics

THE torr has recently been adopted as the British standard unit for the measurement of pressure in vacuum physics; but the fact that proposals have been made for further change[1,2] indicates that the present system is not yet satisfactory. The recent proposals have been concerned with definition of units; but the practical expression of pressures in terms of these units appears also to be due for revision.

The range of pressures encountered in vacuum physics is at present about 10^3–10^{-11} torr, so that to cover this range with a single unit the conventional method is to use the exponent; the alternative method of expression of pressures as small decimal fractions of a torr is obsolescent, and its main continued use appears to be in the usual calibration of the scale of the McLeod gauge. Thus we are at present expressing pressures less than atmospheric with a range of exponents which may be positive or negative, with the zero exponent corresponding to no clearly recognizable pressure. As improvements in high-vacuum techniques continually decrease the pressures attainable in vacuum systems the problem of expression becomes aggravated as we are forced to use larger negative exponents; this makes more obvious the terminological inconsistency of a 'higher' vacuum corresponding to a smaller number.

A similar problem, the expression of hydrogen-ion concentration in aqueous solution, was elegantly solved by the introduction of the pH scale, which has been universally adopted and has proved satisfactory over many years of use. In most vacuum measurements the problem is quite analogous; we are concerned mainly with the order of magnitude of the pressure.

It is proposed therefore that the new unit the vac[2], which has excellent theoretical justification, would be an ideal basis for a p Vac scale. If zero on the scale is taken as 10^3 vac, which is almost one standard atmosphere, it is possible to define a scale analogous to the pH scale:

$$p\,\text{Vac} = -\log \text{vac} + 3$$

Thus, zero is atmospheric pressure, all practical vacua will be positive, and the larger p Vac, the higher the vacuum.

The Special Theory of Electromagnetism

THE law of addition of collinear velocities as derived from the Lorentz transformation in special relativity is:

$$W = \frac{U + V}{1 + UV/c^2} \tag{1}$$

U and V being the components, W the resultant velocity and c the velocity of light. It follows that W can never be greater than c.

Despite this failure in kinematics of the classical law of vector addition, that law is still used in other fields of physics. This communication shows what modifications to electrostatic theory are necessary if a rule analogous to equation (1) is adopted in its place.

Introducing 'electric interval' $d\sigma$ by the relation:

$$d\sigma^2 = dr^2 - \varkappa^{-2}d\varphi^2 \tag{2}$$

where dr and $d\varphi$ have their usual meaning for an observer and $\varkappa$ is a universal constant, the addition of collinear electric vectors now follows the rule:

$$E = \frac{E_1 + E_2}{1 + E_1E_2/\varkappa^2} \tag{3}$$

and $\varkappa$ is recognized as the limiting attainable resultant, presumably corresponding to a break-down field-strength.

Discrepancies from classical theory will be imperceptible in weak fields, so that support for the new hypothesis must be sought under conditions near breakdown.

Considering the inverse square law, a geometrical concept in which the possible effect of the field on measurement of distance is ignored, it appears that distance must be replaced by interval in its formulation, so that the field of an electron is represented by :

$$\frac{d\varphi}{d\sigma} = -\frac{e}{\sigma^2} \qquad (4)$$

e being the charge. The measured field-strength is then :

$$\frac{d\varphi}{dr} = -e(\sigma^2 + e^2/x^2)^{-1/2} \qquad (5)$$

which compares with the Born and Infeld formula.

CRYSTALLOGRAPHY

Out-of-Focus Electron Microscope Images of Edges of Crystal Lattices

IN a recent communication, Hashimoto and Watanabe[1] report the observation of extra lines outside the geometric bounds of the electron microscope image of a crystal of copper phthalocyanine when the microscope is de-focused to obtain the Fourier image of order $N = \frac{1}{2}$ (see Cowley and Moodie[2]). They state that "such lines are not explicable by the theory of Cowley and Moodie"

The paper of ours[2] to which they refer contains not only a discussion of such effects as essential components of the concept of Fourier images but also a sequence of out-of-focus images obtained from an amplitude object with visible light which clearly demonstrates that such effects occur. The periodic object in our case was interrupted by a small internal non-periodic region, rather than by a sharp external boundary as in the case quoted by Hashimoto and Watanabe ; but the progressive extension of the periodic grating image across the boundary as the order number of the Fourier image increases is clearly visible. Their electron micrographs may, in fact, be considered as further evidence in favour of our contentions at that time : they demonstrate that Fourier image phenomena are present and important in the electron microscope imaging of crystal lattices.

It appears that Hashimoto and Watanabe have considered not our theory of Fourier images but the simplification of it represented by their Fig. 2 and associated discussion, which ignores Fresnel diffraction effects and cannot, therefore, give an adequate account of the observation under discussion. This limitation should not, however, be attributed to our theory.

The Fourier image theory which we presented in our initial paper[2] was developed in detail only for periodic objects. It may be applied equally well to non-periodic objects. In either case, however, the theory is more conveniently developed on the basis of our reformulation of physical optics theory presented in later papers[3,4]. If we assume the incident radiation to be coherent and plane-parallel, the complex amplitude of the wave in an image out-of-focus by an axial distance, R, is given by :

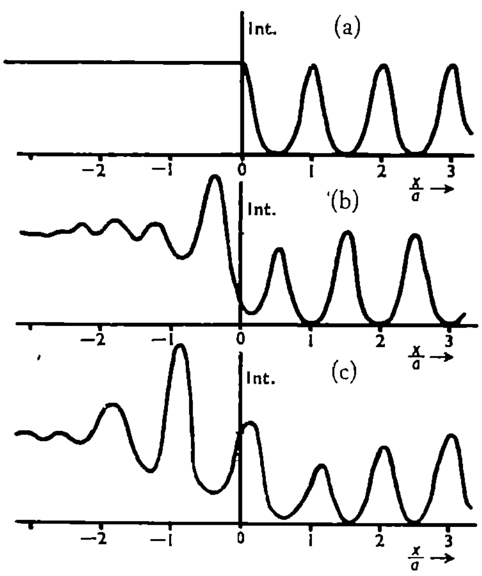

Fig. 1. The calculated intensity distribution at the edge of a periodic amplitude object of the form $\frac{1}{2} + \frac{1}{2}\cos(2\pi x/a)$, (*a*) in focus image (Fourier image of order $N = 0$), (*b*) out-of-focus (Fourier image of order $N = \frac{1}{2}$), and (*c*) Fourier image of order $N = 1$

$$\psi(x,y) = q(x,y) \star \exp\{-ik(x^2 + y^2)/2R\} = \iint q(X,Y)\exp\{-ik[(x-X)^2 + (y-Y)^2]/2R\}\mathrm{d}X.\mathrm{d}Y$$

where $q(x,y)$ is the transmission function of the object. The intensity distribution is then given by $I(x,y) = \psi(x,y).\psi^*(x,y)$.

For the particular case of a crystal edge considered by Hashimoto and Watanabe, we may put :

$$q(x,y) = q_1(x,y).S(x) + S(-x)$$

where $q_1(x,y)$ is the periodic transmission function for an infinite, periodic crystal lattice and $S(x)$ is the step-function :

$$S(x) = \begin{cases} 0 \text{ for } -\infty < x < 0 \\ 1 \text{ for } 0 < x < \infty \end{cases}$$

If we put $q_1(x,y) = \frac{1}{2} + \frac{1}{2}\cos(2\pi x/a)$, which corresponds to an amplitude grating similar to that used by Hashimoto and Watanabe as an optical analogue, the calculated intensity distributions are as shown in Figs. 1*a*, *b* and *c* for the Fourier images of order $N = 0$, $N = \frac{1}{2}$ (that is, $R = a^2/\lambda$) and $N = 1$ (that is, $R = 2a^2/\lambda$). Figs. 1*a* and *b* clearly reproduce the relevant features of the intensity distributions, including the one relatively strong and two weak lines beyond the edge of the grating, visible in their Figs. 3*a* and *b* (ref. 1).

In the same way we may calculate the intensity distribution to be expected at the boundary in an out-of-focus image of a copper phthalocyanine crystal if we put :

$$q_1(x,y) = \exp\{i\sigma\varphi(x,y)\}$$

where $\varphi(x,y)$ is the periodic function representing the projection of the potential distribution in the crystal lattice and σ is a constant. It has been established that, to a first approximation, thin crystals act as phase gratings for electrons[5] and a study has been made of the contrast in Fourier images of such gratings[6]. We hope to publish elsewhere a more detailed account of the images of crystal lattices formed in electron microscopes.

CHEMICAL ENGINEERING

A Rapid Method for the Determination of Tetramethyl Lead and Tetraethyl Lead in Petrol

THE use of tetramethyl lead as anti-knock additive in petrol sets a new problem to the petroleum laboratories in connexion with the determination of these additives. The standard A.S.T.M. method *D* 526–56 cannot be used for the analysis of petrols containing a mixture of tetramethyl lead and tetraethyl lead or for the determination of lead in a sample containing alkylated lead additives.

We have tried to work out a rapid method for the qualitative determination of tetramethyl and tetraethyl lead in petrols. First, we tried to use a colour reaction with dithizone reagent. Dithizone in chloroform solution is added to the petrol. The mixture is shaken with water and a red colour appears in the organic phase. The reaction mechanism is apparently different for the tetramethyl and the tetraethyl lead. Tetraethyl lead seems to be less stable than tetramethyl lead; it hydrolyses more quickly and a red colour appears, whereas tetramethyl lead does not undergo any reaction. This test being extremely sensitive (limit $0{\cdot}04\gamma$), errors due to impurities in glass or water are likely to occur. It is also unsuitable for use with a red-coloured petrol.

We therefore tried another method, using petrol fractions obtained by distillation. Afterwards, we examined the different fractions by means of a Zeiss flame spectrophotometer *M4Q* at 406 mμ in order to determine the lead.

Generally, we have taken four fractions and the residue: initial boiling point to 100° C.; 100° to 125° C. (fraction containing the tetramethyl lead); 125° to 150° C.; 150° to 175° C.; and the residue (containing the tetraethyl lead). About 250 c.c. of petrol are distilled on a 'Vigreux' column (30 cm. in length), in 2 hr. We observed that the slower the distillation, the better the separation of the lead in the spectrophotometric determination.

To check the method, we used a platformate containing tetramethyl lead, a platformate containing tetraethyl lead and a platformate containing tetramethyl and tetraethyl lead. The figures in Table 1 indicate the galvanometer readings expressing the light intensity of the flame. The apparatus was standardized at a reading of 50 with a platformate containing 4·2 c.c. tetramethyl lead per Imperial gall. An oxy-acetylene flame is used. Only the figures in the horizontal lines of the table should be compared with each other. In this determination we did not consider the flame background of the different fractions. Since these results on lead distribution in known mixtures were reasonable, we examined commercial samples. The results are summarized in Table 2.

The petrols showing high readings in the 100° to 125° C. fraction were those giving aberrant results in the *A*.S.T.M. determination *D* 526–56. Moreover, these results tally with those advertised by petroleum companies. The method given here is simple and allows one to estimate tetramethyl and tetraethyl lead. Anti-knock quantitative analysis may be carried out in the usual way.

CHEMISTRY

Influence of Chemical Isomerism on the Szilard–Chalmers Processes in Solids

THE recent appearance[1] of a communication concerning the Szilard–Chalmers effect in *cis*- and *trans*- dichloro- *bis* (ethylenediamine) cobalt (III) nitrate prompts us to report the following results.

A considerable amount of work has been published in which processes associated to the Szilard–Chalmers effect are studied in solid-state complex combinations.

Less attention, however, has been given to the influence of chemical isomerism. The question arises whether in two chemical isomers the annealing of reactor irradiation damage occurs in the same way.

Zuber[2] was the first to study the Szilard–Chalmers effect in crystalline D-[Co en$_3$](NO$_3$)$_3$. After irradiation of the dextro complex and the addition of lævo isomer as carrier, he found by resolving [Co en$_3$](NO$_3$)$_3$ that, of 5 per cent annealed atoms after irradiation, only 4·5 per cent annealed as the dextro, and 0·5 per cent annealed as the lævo, isomer. It would be interesting to examine also the irradiated lævo isomer and to compare the behaviour of the two isomers. Recently, Saito and co-workers[3], investigating the behaviour of hot bromine atoms in cobalt complex salts, found no noteworthy differences in the yield of complexed radiobromine for *cis–trans* isomers. They did not examine the retention of radiocobalt.

Our attempts to find evidence of differences in the behaviour of chemical isomers in radiocobalt annealing processes were more successful. Cobalt complex combinations exhibiting geometrical, optical, hydration, ionization, or linkage isomerism were irradiated for 40 hr. in the *IFA* reactor. The samples were irradiated in aluminium ampoules in air. The irradiation conditions were as follows: thermal neutron flux, $6 \cdot 0 \times 10^{11} n$. cm.$^{-2}$ sec.$^{-1}$; fast neutron flux, $1 \cdot 75 \times 10^{11}$ n. cm.$^{-2}$ sec.$^{-1}$; gamma dose-rate, $1 \cdot 31 \times 10^{7}$ r. hr.$^{-1}$.

The fraction annealed after irradiation was determined via retention, using a well-known analytical technique for the separation of recoiled radiocobalt[4,5]. The results are given in Table 1, together with the difference in retention for a pair of isomers.

These investigations are continuing, but some conclusions may already be drawn. It appears that chemical isomerism plays an important part in the recombination process of recoil fragments occurring simultaneously with irradiation. This would be expected also when taking account of the influence of the steric factor on the annealing process. The difference in the spatial arrangement of groups corresponding to the same general formula certainly influences the interatomic distances and the internal field of the crystal. In addition, the influence of chemical groups which may act differently depending on their function in the molecule must be considered.

The greatest differences are observed with the hydration isomers, where the water of hydration has at first sight a reducing effect on the recoiled radiocobalt, a view which has been thought to apply to permanganate salts[6]. It is only known that water molecules behave differently when co-ordinated to cobalt. The geometrical isomers exhibit also considerably different retentions. It was observed that the *cis*-position is more advantageous, the annealing being lower for the *trans*-position where steric factors cause serious hindrance. For ionization and linkage isomers it was found that the chemical bond has some influence. The differences in the retention of lævo- and dextro-combinations though smaller are present. Here also the steric factor plays a part, although the differences do not act in the same direction.

Table 1. RETENTIONS OF CHEMICAL ISOMERS AFTER REACTOR IRRADIATION

Isomerism	Chemical formula	Retention (R per cent)	Difference in retention (ΔR per cent)
Hydration	[Co(NH$_3$)$_4$Cl(OH$_2$)]Cl$_2$	68·2	39·0
	[Co(NH$_3$)$_4$Cl$_2$]Cl.H$_2$O	29·2	
Geometrical	*cis*-[Co en$_2$Cl$_2$]Cl	79·8	15·2
	trans-[Co en$_2$Cl$_2$]Cl	63·7	
	cis-[Co(NH$_3$)$_4$(NO$_2$)$_2$]NO$_3$	86·6	10·8
	trans-[Co(NH$_3$)$_4$(NO$_2$)$_2$]NO$_3$	75·8	
Linkage	[Co(NH$_3$)$_5$NO$_2$]Cl$_2$	71·1	6·8
	[Co(NH$_3$)$_5$ONO]Cl$_2$	77·9	
Ionization	[Co(NH$_3$)$_5$SO$_4$]Br	75·0	5·5
	[Co(NH$_3$)$_5$Br]SO$_4$	69·5	
Optical	D-[Co en$_3$](NO$_3$)$_3$	71·9	1·7
	L-[Co en$_3$](NO$_3$)$_3$	73·6	
	D-[Co en$_3$]Br$_3$.2H$_2$O	89·9	6·4
	L-[Co en$_3$]Br$_3$.2H$_2$O	83·5	

So far only qualitative investigations have been discussed. A systematic investigation involving analysis of recombination products and kinetic measurements is in progress and the results will be reported in due course.

Interactions of NO_2–N_2O_4 and Niobium Dioxide (NbO_2)

THE interaction of NO$_2$ and niobium dioxide (NbO$_2$) was studied as part of a general programme to investigate the oxidation chemistry of NO$_2$ with respect to its effect upon potentially non-stoichiometric oxides. Other oxides which have been investigated have shown that NO$_2$ may act as an oxidizing agent as well as a nitrating and nitriting agent. In addition, significant quantities of physically and chemisorbed NO$_2$ are always encountered in this type of interaction[1]. In a brief introductory study carried out on niobium oxide a number of significant points were uncovered which expand the present investigations.

Niobium dioxide was prepared by reduction in a stream of dry hydrogen at 950° C. The NO$_2$ was obtained from the Matheson Chemical Co. It was transferred to the vacuum line through a magnesium perchlorate trap, and was fractionated until the solid condensate was white. At all temperatures in the range of 100–500° C. and pressure of NO$_2$ of 0·014–65 cm. mercury the oxidation of the dioxide proceeded at a rapid rate, such that the composition of Nb$_2$O$_5$ was established nearly instantly. In many cases the dioxide acted as pyrophor, igniting and immediately producing the penta oxide. For the lower pressures and lower temperatures the oxidation proceeded more slowly and was noted to take several minutes for completion. In general, the rapidity of the reaction made a study of the kinetics impossible.

Analysis of the reacted product indicated that the composition of the final product was in all cases within 0·02 stoichiometric unit of the composition NbO$_{2\cdot5}$. This was further confirmed by observing the optical reflectance in the ultra-violet. In addition

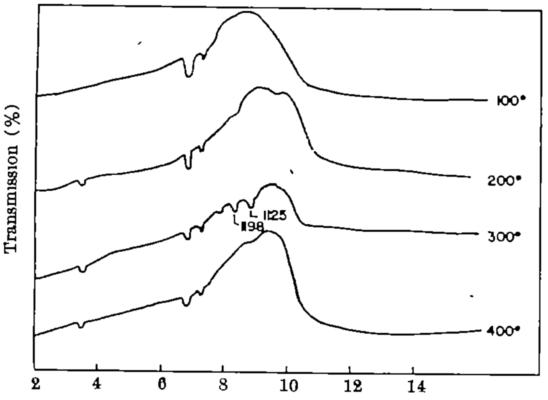

Fig. 1. Infra-red spectrum of the interaction product of niobium dioxide and nitrogen dioxide for various temperatures of interaction at a pressure of 65 cm. nitrogen dioxide

to the above stoichiometric ratio it was noted that a small amount of nitrogen was also incorporated in the oxide. At a pressure of 26·5 cm. mercury of NO_2 and in the temperature interval from 100 to 500° C. the stoichiometric ratio of nitrogen–niobium varied linearily with increasing temperature from 0·019 to 0·043 and at a $P_{NO_2} = 0·014$ cm. mercury the nitrogen content was within the limit of error of the method[2].

In an attempt to determine the origin of this incorporated nitrogen the infra-red spectra of the reacted material was obtained. This was done on a Perkin Elmer model 221 double-beam spectrophotometer. The spectra are partially reproduced in Fig. 1 for the interaction of NO_2 at 65·5 cm./mercury and Nb_2O_4 in the temperature-range of 100–500° C. Absorption peaks may be seen at ~ 3·5, 6·8, and 7·3μ due to interference from the 'Nujol' mulling agent. Secondly, a broad band is in evidence which begins at about 10·5μ. This is most probably due to the Nb–O stretching frequency[3,4]. Finally, bands may be seen at ~ 7·8, 8·3, 8 8 and 9·6μ. It is felt that the bands at 7·8 and 9·6 are probably due to the presence of some form of ionic nitrate[5] as these bands have been found to be characteristic of ionic nitrates in general. The bands at 8·3 and 8·8 appear to be due to the NO_2 group, in the form of strongly chemisorbed nitrogen dioxide or as the nitrite group[6]. It should be noted that in both these cases the presence of these species occurs at an extremely low concentration and thus does not demonstrate the inherent basic character in niobium dioxide.

This work was performed under a subcontract of the Lincoln Laboratory, Massachusetts Institute of Technology, which is operated with support from the U.S. Army, Navy and Air Force.

Dissociation Energy of Aluminium Monobromide

IN a recent review[1] of the dissociation energies of the gaseous monohalides of boron, aluminium, gallium and thallium, it was concluded that the best value for D_0'' (aluminium monobromide) is 105 k.cal. mole^{-1}. Dr. P. Gross has now kindly directed my attention to the work of Semenkovich[2], who has determined the standard heat of formation of gaseous aluminium monobromide by a thermochemical method similar to that used by Gross, Campbell, Kent and Levi[3] for aluminium monofluoride and monochloride. Semenkovich obtains $Q_f(\text{AlBr}_g) = +1·1$ k.cal. mole^{-1}. With $\Delta_s H(\text{Al}) = 77·4$, $Q_f(\text{Br}_g) = 26·71$, and $D_{298}'' - D_0'' = 0\ 85$, $D_0''(\text{AlBr}) = 102\ 2$ k.cal mole^{-1}. As with AlF and AlCl, this value is a little lower than two of the spectroscopic estimates from the state $A\,^1\Pi$, which, for AlBr, are 106·9 k.cal. by extrapolation, and >104·4 k.cal. from the highest observed vibrational level: it is, however, consistent with a predissociation limit which leads to $D_0'' \leqslant 105·7$ k cal.

Triplet Bands of Carbon Monoxide: the System $e\,^3\Sigma^- - a\,^3\Pi$

SOME years ago, in a study of the triplet system, $d(?^3\Pi) - a^3\Pi_r$ of carbon monoxide, Herman and Herman[1] observed a progression of bands of similar appearance which they assigned to a new system. They suggested that the upper state of this system was d and that the lower state was a new triplet-level, lying close to $a^3\Pi$. Later work[2,3] on the forbidden systems of carbon monoxide observed in the absorption spectrum in the Schumann region has provided detailed information about some of the triplet-levels, and the object of this communication is to show that the Herman system arises in fact from the transition $e\,^3\Sigma^- - a\,^3\Pi_r$.

In Table 1, the second column gives values of band-origins of the $e - X$ system[4]. Positions of the band-heads of the Herman system[1] are given in columns three and four. The results of subtracting column four from two are given in column five. These figures are as constant as could be expected, and indicate that the bands form a progression involving the levels $v' = 2$ to 7 of $e\,^3\Sigma^-$. The mean value for the height of the lower level above $v = 0$ in the ground-state $X\,^1\Sigma^+$ is 48,520·$_5$ cm.$^{-1}$.

Table 1

v	$e-X$	$e-a$		$a-X$
	ν_0	λ	ν	ν
7	71,926 5	4,270 8	23,408 3	48,518 2
6	70,966·2*	4,454·5	22,442·9	523 3
5	69,986 4	4,657 2*	21,465 9*	—
4	68,987 9*	4,885 0	20,465 1	522 8
3	67,970 3	5,140 3	19,448 7	521 6
2	66,933 3	5,428 3	18,416 9	516 4

* Interpolated value.

The measurements of band-heads given in Table 1 refer to the longest wave-length heads of groups of three. For the $v' = 2$ and $v' = 3$ bands, further measurements are available[4]:

5428·3 Å.	18,416·9 cm.$^{-1}$		5140·3 Å.	19,448·7 cm.$^{-1}$	
		46·9			46·3
14·5	463·8		28·1	495·0	
		41·0			45·3
02·5	504·8		16·2	540·3	

The mean separation between adjacent heads is thus about 45 cm.$^{-1}$ and the origin of the lower state may be estimated to lie at 48,520·$_5$ − 45 = 48,475·$_5$ cm.$^{-1}$ above $X\ ^1\Sigma^+$. This estimate is in excellent agreement with the value of ν_{00} for $a^3\Pi$ -- $X^1\Sigma^+$ obtained from the rotational analysis[5] of the Cameron bands, namely, 48,473·9$_7$ cm.$^{-1}$.

It seems, therefore, quite certain that the Herman bands form the $v' - 0$ progression in the transition $e\ ^3\Sigma^- - a\ ^3\Pi$. No doubt other bands of this system remain to be found at longer wave-lengths.

Identification of the Radical $\cdot CH_2(CO_2H)$

IN recent years a number of free radicals trapped in irradiated solids have been identified from their electron-spin resonance spectra. In particular, radicals of the form $XH\dot{C}CO_2H$ or $XH\dot{C}CO_2^-$ are known with $X = CH_3$ (ref. 1), NH_3^+ (ref. 2), OH (ref. 3), CO_2H (ref. 4), Cl (Pooley, D., and Whiffen, D. H., unpublished work), CH_2CO_2H (ref. 5), and $CH_2.CH_2CO_2H$ (unpublished work by A. H., J. R. M. and D. H. W.). Hitherto, however, the parent radical $\cdot CH_2(CO_2H)$ has remained unidentified. This radical has now been identified in γ-irradiated malonic acid, $CH_2(CO_2H)_2$. McConnell *et al.*[4] have fully investigated the radical $\dot{C}H(CO_2H)_2$ which is also formed when malonic acid is γ-irradiated; they reported that lines not due to $\cdot CH(CO_2H)_2$ appeared in the spectra of freshly irradiated crystals, and could be removed by heating the crystals to 50° C. for 24 hr.

A detailed study of the spectrum of irradiated malonic acid was undertaken using an electron resonance spectrometer operating at 9,000 Mc./s. A single crystal of malonic acid was γ-irradiated at liquid-nitrogen temperature. Its room-temperature spectrum indicated that at least three radicals were present. For a general orientation of the crystal with respect to the magnetic field, all three radicals have different *g* values, and each has a spectrum symmetrical about its own centre. If the hyperfine structure of the spectrum of each radical can be analysed, it is possible to identify the radical. For some crystal orientations, however, exact analysis is difficult because of overlapping of the spectra of different radicals. The spectrum of a freshly irradiated single crystal of malonic acid consisted of two exceedingly strong and narrow lines due[4] to the radical $\cdot CH(CO_2H)_2$. In addition, we observed four sharp lines of equal intensity approximately one-fifth as strong as the spectrum of $\cdot CH(CO_2H)_2$. A third radical was also present, but its spectrum was still weaker and the radical has not yet been positively identified.

The spectrum of intermediate intensity indicates the presence of a radical in which there is hyperfine interaction with two hydrogen nuclei. This spectrum could be analysed for a sufficient number of orientations to obtain a complete coupling tensor for each hydrogen atom. However, the precision is less than that which would be attainable if this were the only radical present. The principal values of the coupling tensor of one hydrogen atom were −91, −56 and −30 Mc./s., and for the other −92, −59 and −37 Mc./s. These values are essentially those to be expected for a hydrogen atom attached directly to the free radical centre[3,4,6]. They have therefore been given a negative sign, although this is not obtained directly from the spectra. The coupling tensors identify the radical as $\cdot CH_2(CO_2H)$, since no other radical with two hydrogens on the free-radical carbon atom is anticipated from the irradiation of malonic acid. The slight differences between the two tensors are less than the probable experimental error (±4 Mc./s.), although the two hydrogen atoms are not in crystallographically equivalent positions in the trapping site, and their coupling tensors need not, therefore, be absolutely identical. It appears that the methylene group ($\text{—}\dot{C}H_2$) in the radical is not rotating about the C—C bond, since free rotation would lead to a spectrum having three hyperfine lines with intensity ratios 1 : 2 : 1 for all crystal orientations.

It is expected[2,6] that the least negative, intermediate, and most negative principal values of the coupling tensor will occur for directions parallel to the C—H bond, perpendicular to the plane of the radical, and in the plane of the radical but perpendicular to the C—H bond, respectively. The intermediate axes for both tensors therefore should be parallel to each other. This was found to be the case, the experimental value for the angle between the intermediate axes of the two tensors being 4° with an error of approximately 5°. The major and minor axes of each tensor should intersect at an angle equal to the HCH angle. This angle was calculated from the tensors to be 116 ± 5°. In a planar radical, this angle would be 120° for strict sp^2 hybridization, although van der Waals repulsion between the hydrogen atoms and the carboxylic acid group might give rise to a slight reduction in this value.

The electron-resonance spectra of irradiated malonic acid thus support a planar structure for the substituted methyl radical, in agreement with previous work[7] on the methyl radical itself.

This investigation was undertaken as part of the programme of the Basic Physics Division of the National Physical Laboratory, and will be published in detail elsewhere. This report is published by permission of the Director.

BIOCHEMISTRY

Fatty Acid Specificity for the Esterification of Vitamin A and Cholesterol by Intestinal and Pancreatic Enzymes in Rats

Vitamin A and cholesterol esters have been shown to undergo extensive hydrolysis in the lumen of the small intestine during the process of absorption; they are re-esterified to appear in the lymph mostly as esters[1,2]. However, the vitamin A esters of the lymph, blood and liver of the rat are formed by long-chain fatty acids[3] and in the normal rat liver, probably as palmitates[4]. On the other hand, cholesterol esters are usually made up of poly-unsaturated fatty acids in the lymph and blood of rats[5]. For the absorption of the two lipid materials, the enzymes of the pancreas have been largely implicated, while not much attention has been paid to the possible role of the mucosal enzymes. From the behaviour of the mucosal enzymes, as presented here, it appears that probably these enzymes play a more important part in the re-esterification of the two lipid materials during their absorption.

Acetone-dried powder was prepared from the intestinal mucosæ and pancreas of normal stock rats of this Institute by grinding the tissues in 10 vol. of acetone pre-cooled to −15°. The powder was suspended in cold distilled water in the proportion of 1 gm. powder per 10 ml. water for 1 hr. and was then centrifuged for 10 min. at 10,000*g* in the cold. The clear supernatant liquid was suitably diluted and used as the source of the enzymes. The reaction mixtures for cholesterol esterification contained 5 μmoles of free cholesterol and 10 μmoles of the given fatty acid in 0·5 ml. of ethanol, 3 ml. of Michaelis veronal buffer (0·1 *M*), *p*H 6·1, 25 mgm. of sodium taurocholate and the enzyme extracts representing 10 mgm. of pancreatic or 25 mgm. of intestinal powder. The final volume was made up to 5 ml. and incubation was for 30 min. for pancreas and 60 min. for intestine at 37°. The reaction mixtures for vitamin A esterification contained 1 μmole of vitamin A alcohol and 2 μmoles of the given fatty acids in 0·5 ml. ethanol, 3 ml. of Michaelis veronal buffer (0·1 *M*), *p*H 6·6 and the enzyme extract representing 2 mgm. of pancreatic or 5 mgm. of intestinal powder. The final volume was made up to 5 ml. and both were incubated for 30 min. at 37°. The reaction mixtures were extracted twice with light petroleum ether (40–60°) after stopping the reactions by the addition of 5 ml. of ethanol. We have been using chromatographic procedures for the separation of vitamin A ester and alcohol, and we have found that the same method can be used for the quantitative separation of free and esterified cholesterol also. The two forms of vitamin A and cholesterol were, therefore, separated on alumina columns[6] and estimated as described previously[7].

Results summarized in Table 1 clearly show that both pancreatic and intestinal enzymes esterify cholesterol preferentially with unsaturated fatty acids. Our findings with the pancreatic enzymes agree broadly with the earlier reports of Hernandez and Chaikoff[8] and Swell *et al.*[9], who have shown that the presence of unsaturation in the fatty acid is necessary for the effective esterification of cholesterol by the pancreatic enzymes. However, according to Hernandez and Chaikoff[8], while oleic and linoleic acids showed almost the same rates of esterification, linolenic acid was only 13 per cent as active as oleic acid, and our results with the pancreatic enzymes show linoleic and linolenic acids to be 68 and 40 per cent as efficient as oleic acid. In contrast, as demonstrated here, the mucosal enzymes exhibit progressively increased esterification with increase in the unsaturation of the fatty acid. If the pancreatic enzymes were to re-esterify cholesterol for its transport during absorption, the oleate should be the major ester in the lymph and blood, but in these tissues the cholesterol is found esterified mostly with polyunsaturated fatty acids[10–12]. It thus seems clear that the mucosal enzymes, rather than the pancreatic enzymes, are responsible for the re-esterification of cholesterol during absorption.

Table 1. Fatty Acid Specificity for the Esterification of Vitamin A and Cholesterol by the Enzymes of Intestine and Pancreas of Rats

Fatty acid	mμmoles cholesterol esterified/mgm. protein/hr.		mμmoles vitamin A alcohol esterified/ mgm. protein/hr.	
	Pancreas	Intestine	Pancreas	Intestine
Acetic	0·0	0·0	3·0	2·3
Butyric	0·0	0·0	2·3	1·5
*Iso*valeric	0·0	0·0	2·3	2·3
Caproic	0·0	0·0	2·3	1·5
Lauric	60·0	7·5	938·0	285·0
Myristic	40·0	5·0	868·0	142·5
Palmitic	47·5	5·5	896·0	159·0
Stearic	50·0	5·7	798·0	139·5
Oleic	1,313·0	50·0	840·0	130·5
Linoleic	885·0	71·5	854·0	135·8
Linolenic	515·0	82·0	882·0	132·0

Regarding the esterification of vitamin A, neither tissue showed any preference for unsaturation, and it was effectively esterified with fatty acids containing more than 12 carbon atoms by both the tissues. It should be mentioned here that Pollard and Bieri[13] had similar experience with chick pancreas. This again would explain the presence of higher fatty acid esters of vitamin A in the blood and lymph of rats[3].

In vitro Decarboxylation of Tryptophans by Mammalian Decarboxylase

TWENTY-TWO tryptophans have been examined in order to check the specificity of the so-called 5-hydroxytryptophan decarboxylase[1,2], and at the same time to see whether any of these compounds could be decarboxylated at a rate similar to that known for 5-hydroxytryptophan (5-HTP). The present work was intended as preliminary to further investigations on the possibility of non-biogenic tryptophans interfering in the biosynthesis, actions and metabolism of endogenous 5-hydroxytryptamine (5-HT), especially of brain 5-HT.

The tryptophans examined were the following: L-tryptophan, DL-5-hydroxytryptophan, DL-4-hydroxytryptophan (4-HTP), DL-6-hydroxytryptophan, DL-7-hydroxytryptophan, DL-2-hydroxytryptophan, DL-α-*iso*-5-hydroxytryptophan, DL-5-methyltryptophan, DL-5-methoxytryptophan, DL-5-benzyloxytryptophan, DL-5-nitrotryptophan, DL-5-aminotryptophan, DL-5-hydroxy-β-methyltryptophan, DL-5-hydroxy-N,N-dimethyltryptophan, DL-5-hydroxy-6-methoxytryptophan, DL-5-hydroxy-2-methyltryptophan, DL-5-benzyloxy-6-methoxytryptophan, DL-5-hydroxy-N-acetyltryptophan, DL-5-acetoxy-N-acetyltryptophan, DL-4-methyltryptophan, DL-4-benzyloxytryptophan, DL-6-benzyloxytryptophan.

The enzyme preparations were obtained by centrifugation of homogenates of different guinea pig, rat, mouse and rabbit tissues in a Spinco preparative centrifuge, at 15,000 r.p.m. Decarboxylation was carried out in a conventional Warburg apparatus, at 38° C. and *p*H 7·4. The flasks contained 4 m.moles of the substrate amino-acid, 50 μmgm. pyridoxal phosphate, 0·07 μmole phosphate buffer, *p*H 7·4, and 2 ml. of the enzyme preparation, corresponding to 1 gm. fresh tissue. The total volume in the flasks was 2·4 ml. Carbon dioxide produced was determined 15 min. after the addition of 0·2 ml. of *N* sulphuric acid.

Of the tryptophans examined only 5-HTP, 4-HTP, 5-hydroxy-N-acetyltryptophan and 5-acetoxy-N-acetyltryptophan were found to be decarboxylated using the above conventional, and not very sensitive, Warburg technique.

However, as clearly shown by *in vivo* studies, decarboxylation of 5-hydroxy-N-acetyltryptophan and 5-acetoxy-N-acetyltryptophan was preceded by their hydrolysis to 5-HTP. Thus, only 5-HTP and 4-HTP actually acted as substrates for the decarboxylase.

Table 1 shows the results of a 30-min. incubation of DL-5-HTP, DL-4-HTP and dopa (3,4-dihydroxyphenylalanine was used only for the sake of comparison) with enzyme preparations from various tissues.

The carbon dioxide expected for complete decarboxylation was 44·7 μl. Addition of a mixture of 4-HTP and 5-HTP to a guinea pig kidney decarboxylase preparation led to a stoichiometric liberation of carbon dioxide consistent with the decarboxylation of both substrates.

The enzymic activity of the guinea pig kidney preparation was strongly inhibited, at *p*H 6·8, by the addition of α-methyldopa (8μmoles), caffeic acid (8 μmoles) and cynarine (8 μmoles). However, inhibition of decarboxylation of 5-HTP was more complete than that of 4-HTP and dopa.

In sharp contrast to dopa, neither 5-HTP nor 4-HTP was attacked by bacterial decarboxylase (acetone-dried cells of *Streptococcus faecalis* R.).

Table 1. *In vitro* DECARBOXYLATION OF 5-HTP, 4-HTP AND DOPA BY ENZYME PREPARATIONS FROM DIFFERENT TISSUES

Enzyme preparation	Substrate	Carbon dioxide formed in 30 min. (μl.)
Guinea pig liver	5-HTP	32·0
,, ,, ,,	4-HTP	39·0
,, ,, kidney	5-HTP	42·2
,, ,, ,,	4-HTP	33·0
,, ,, ,,	Dopa	41·5
,, ,, intestine	5-HTP	37·5
,, ,, ,,	4-HTP	36·5
,, ,, ,,	Dopa	40·0
Rat intestine	5-HTP	0
,, ,,	4-HTP	0
,, ,,	Dopa	0
Mouse brain	5-HTP	12·5
,, ,,	4-HTP	20·0
Rabbit lung	5-HTP	0
,, ,,	4-HTP	0

The above experimental results show that the so-called 5-HTP-decarboxylase is not an enzyme specific to 5-HTP, and that 4-HTP may be the precursor amino-acid of the 4-hydroxyindolealkylamines (psilocin and psilocybin) occurring in the living organism. In a recent paper, Udenfriend, Lovenberg and Weissbach[3] also suggest that the existence of separate dopa and 5-HTP decarboxylase should be withdrawn.

We are indebted to Prof. D. D. Woods, Department of Biochemistry, University of Oxford, who kindly supplied samples of acetone-dried cells of *Streptococcus faecalis* R.; L-tryptophan, DL-5-methyltryptophan and DL-4-methyltryptophan were purchased from Hoffmann-La Roche, Basle; DL-α-*iso*-5-hydroxytryptophan was kindly supplied by Dr. F. Häfliger, J. R. Geigy A.G., Basle; DL-5-nitrotryptophan and DL-5-aminotryptophan were kindly supplied by Dr. G. Cavallini, Vismara Terapeutici, Milan; all the other tryptophans were synthesized in the Farmitalia Research Laboratories, Milan.

An Evaluation of the Use of Digitonin for the Analysis of Fæcal Sterols

NUMEROUS reports have appeared in the literature dealing with the analysis of fæcal sterols[1–3]. Before the complexity of the sterol mixture of fæces was appreciated[4], a commonly employed procedure for the analysis of coprostanol was based on the difference between the total sterol determined by gravimetric analysis of the digitonide of the mixture and the amount of cholesterol or 'chromogenic sterol' calculated from the colour produced with the Liebermann–Burchard reagent[1,2]. While many investigators recognize that the chromogenic property of coprostanol will introduce an error in the analysis if coprostanol is determined as cholesterol using the digitonide precipitation procedure, a more serious error arises from the fact that the digitonide of coprostanol is significantly soluble in many of the solvent mixtures used (for example, the Sperry–Webb determination for cholesterol[5]). This unusual solubility property of coprostanol digitonide was recognized early by Dam[6] when he reported that in contrast to cholestanol digitonide, the digitonide of coprostanol was significantly soluble in methanol, a property which allowed the crude separation of the two sterols. This information prompted us to study the solubility of coprostanol digitonide in the solvent mixture routinely employed in the Sperry–Webb procedure and to compare our results with cholesterol digitonide as a reference.

Cholesterol used for the present work was obtained from Armour and Co. and purified via the dibromide (m.p. 147–8°). The coprostanol was obtained from rat fæces and was previously isolated in this laboratory[7] as a chromatographically pure zone on silicic acid/'Celite'. To eliminate the possibility of the presence of coprostan-3α-ol, the coprostan-3β-ol was further purified through the digitonide (Nutritional Biochemical Company), washed with acetone/ether (1 : 2) and ether, and regenerated as the 3β-sterol by cleavage of the digitonide with pyridine (m.p. 98–99° C.). Standard solutions of cholesterol and coprostanol were prepared in absolute ethanol/acetone (1 : 1) and suitable aliquots (300 μgm.–1,400 μgm.) were analysed in triplicate as follows: The aliquots were transferred to either a centrifuge tube or a colorimeter tube and the ethanol–acetone removed under vacuum at 50–60° C. To the samples in the centrifuge tubes, 2 or 4 ml. of absolute ethanol/acetone (1 : 1 v/v) were added. A drop of 10 per cent acetic acid was added to each tube, and either 1 ml. or 2 ml. of a 0·5 per cent solution of digitonin in 50 per cent ethanol brought the final volume to 3 or 6 ml. respectively. The mixture was heated for 15 min. in a water-bath at 50° C. and allowed to stand for 18–24 hr. In every case, the 5 or 10 mgm. of digitonin added was in excess of the theoretical requirement. The digitonides were washed and dried exactly as described by Sperry–Webb[5]. After the removal of ethanol–acetone and ether from the pooled washings, the remaining sterol was partitioned between ether and water. The ether extract was washed several times with water. The mixture was taken to dryness *in vacuo*, and the recovered sterol determined quantitatively as described here. The quantity of cholesterol and coprostanol was determined colorimetrically in 2 ml. of glacial acetic acid and 4 ml. of Liebermann–Burchard reagent using suitable constants as previously described[4]. As a control the original corresponding aliquot was analysed colorimetrically by the direct addition of 2 ml. of glacial acetic acid and 4 ml. of Liebermann–Burchard reagent.

In the second series, mixtures of coprostanol and cholesterol were analysed in various proportions. In every case the mixtures totalled 800 μgm. of sterol. The sterols were analysed by the same method as described above and compared in each case with the absorbancy obtained for the appropriate control.

The results (Table 1) confirmed the complete recovery of cholesterol digitonide in all concentrations employed for either final volume. The photometric reading of coprostanol digitonide at the 300-μmgm. level is inaccurate and is omitted. The recovery of coprostanol of moderate to high levels in 3 ml. of solvent was found to vary from 97·1 to 70·6 per cent. When the final volume was doubled, an appreciable decrease in recovery was observed for comparable concentrations of coprostanol (65·0–59·6 per cent).

Table 1. RECOVERY OF CHOLESTEROL AND COPROSTANOL DIGITONIDES IN THE SPERRY–WEBB SOLVENT MIXTURE

Weight of sterol	Recovery of digitonide (percentage of total sterol)			
	Cholesterol		Coprostanol	
μgm	3 ml.*	6 ml.*	3 ml.*	6 ml.*
300	100	100	—	—
600	100	100	97·1	65·0
800	100	100	78·6	67·9
1,000	100	100	80·8	63·0
1,400	100	100	70·6	59·6

* The volumes indicated refer to the final volume of the solvent mixture.

Table 2. RECOVERY OF MIXED CHOLESTEROL AND COPROSTANOL DIGITONIDES IN THE SPERRY–WEBB SOLVENT MIXTURE

Composition of sterol mixture* (per cent)		Recovery of mixed digitonides (percentage of total sterol)
Coprostanol	Cholesterol	
0	100	100
25	75	89·4
50	50	88·6
75	25	78·9
100	0	78·6

* Total sterol, 800 μgm., 3 ml. of Sperry–Webb solvents.

Analysis of the mixtures of coprostanol and cholesterol revealed that increasing the proportion of coprostanol resulted in a decrease in the recovery of the mixed digitonide (89·4–78·6 per cent).

The quantity of sterol recovered from the Sperry–Webb washings was found to correspond in each case to that amount of sterol not precipitated by digitonin. Our present results suggests that incomplete precipitation of coprostanol digitonide in the solvents of the Sperry–Webb procedure or equivalent solvents may account for some of the observed quantities of 'non-3β-hydroxy fæcal sterols'[8]. Thus, it is our opinion that fæcal sterol analysis with the above limitations can be more successfully carried out by a suitable chromatographic procedure as previously described[4]. Recent developments in the separation of sterols by quantitative gas chromatography[9] have stimulated much interest in the applicability of this technique to quantitative sterol determinations.

Action of Trypsin on Bence-Jones Protein Derivatives

It is well known that the proteolytic enzyme trypsin fails to hydrolyse native proteins, or hydrolyses them to only a very small extent. The denaturation of protein substrate is therefore a customary preliminary operation in all work involving the action of trypsin on proteins. We report here the effect of trypsin on some chemical derivatives of a pure de-ionized[1] Bence-Jones protein isolated in large amounts from the urine of a single patient.

The protein was oxidized with performic acid, as described by Harrington and Schellman[2], treated with sulphite by the Swan technique as modified by Bailey and Cole[3], reduced with mercaptoethanol in 8 *M* urea as suggested by White[4], or with sodium borohydride[5]. The completeness of reduction was checked by employing the *p*-chloromercuribenzoate spectrophotometric titration described by Sela *et al.*[6]. The reduction products were directly digested or previously carboxymethylated with iodoacetic acid or treated with iodoacetamide.

The trypsin employed was a salt-free twice crystallized commercial preparation (Sigma Lot *T* 30*B*–056).

All digestion experiments were performed in a *p*H-stat (model *TTT*–1*A* Radiometer, Copenhagen) employing 100 mgm. of the protein or its derivative in 4 ml. of de-ionized water brought to *p*H 8·00 with 0·2 *N* sodium hydroxide; 5 mgm. of trypsin in 0·5 ml. of 0·001 *N* hydrochloric acid added in five 0·1-ml. aliquots, each every 15 min. The *p*H was maintained at 8·00 with 0·2 *N* sodium hydroxide; the temperature was 30° C.

The molecular weight of this Bence-Jones protein was assumed to be 36,000 on the basis of physicochemical measurements and of quantitative N-terminal amino-acid determinations.

The results obtained are presented in Fig. 1. It is easy to see that the opening, either oxidative or reductive, of the disulphide bonds leads to the same sensitivity toward trypsin. Even the digestion-rates for the derivatives are similar, though the rate for the simply reduced protein (curve 4) is slower, owing probably to the combination of the free sulphydryl groups to form aggregates.

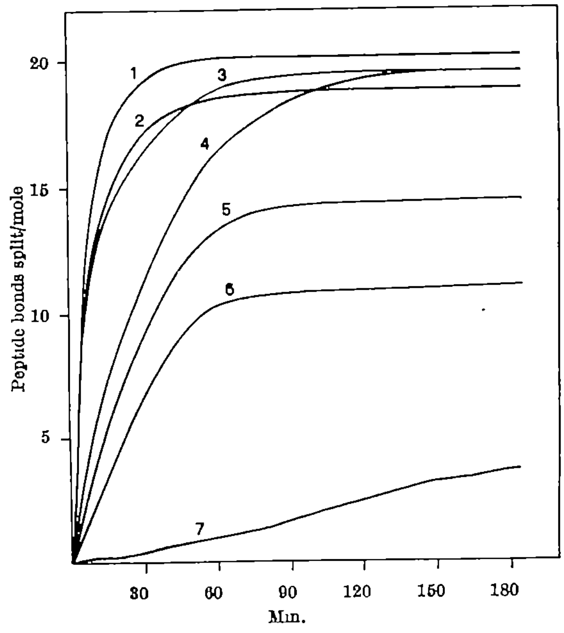

Fig. 1. Tryptic hydrolysis of Bence-Jones protein derivatives. Curve 1, sulphite-treated; curve 2, performic acid oxidized; curve 3, reduced and carboxymethylated; curve 4, reduced; curve 5, in urea 2 *M*; curve 6, in urea 1 *M*; curve 7, native

Bence-Jones protein in urea shows an increasing sensitivity to trypsin with increase of urea molarity (see curves 5 and 6).

It is concluded from the above results that anything which leads to a cleavage of disulphide bonds probably leads to a very similar configuration of the molecule, and that the urea-induced modifications, which respect the integrity of disulphide bridges, result in a lesser sensitivity to trypsin.

The use of tryptic digestion as an auxiliary tool for configurational studies on protein molecule is suggested.

Details of the above work and other results will be published fully elsewhere.

Apparent Reversal of Xanthine Oxidase Action in *Chlorella vulgaris* starved of Nitrogen

In previous publications[1–3] a marked stimulation of the endogenous respiration of *Chlorella vulgaris* and other organisms by numerous purines and purine analogues was described. Several lines of evidence led to the suggestion that these results were best explained by a cyclical oxidation and reduction of the purines, coupled to oxygen on one hand and to the oxidation of fatty acids on the other. This assigns to xanthine oxidase a role in terminal oxidation. This communication presents evidence for an apparent reduction of oxidized purines in *Chlorella*, lending support to the existence of a purine oxidation-reduction cycle.

Chlorella vulgaris (ATCC 11468) was grown and harvested as previously described[1]. Washed cells were suspended in 0·067 *M* phosphate buffer, *p*H 6·0, and incubated with 10^{-4} *M* reduced purines (hypoxanthine or 8-azahypoxanthine) for 15 min before the oxidized purines labelled with carbon-14 were added (final concentration 10^{-4} *M*). After shaking the suspensions in the dark for another 30 min. solid trichloracetic acid was added to a final concentration of 5 per cent. The cell suspensions were centrifuged after 30 min. standing, and this extraction step was repeated twice. Authentic purines or azapurines were added as carriers. The extracts, freed of trichloracetic acid, were concentrated *in vacuo*.

Chlorella cells which had been exposed to hypoxanthine and then to uric acid-2-^{14}C were extracted. Fig. 1 shows the elution pattern of this extract from

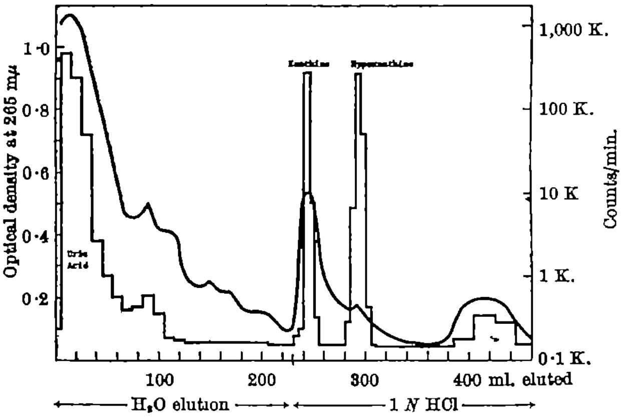

Fig. 1. Distribution of carbon-14 activity in the eluates from a 'Dowex-50(H$^+$)' column. An extract of cells which had been incubated with uric acid-2-^{14}C, together with uric acid, xanthine and hypoxanthine was applied. Boxed line, optical density; continuous line, radioactivity

a 'Dowex 50' column[4]. In addition to uric acid, considerable radioactivity was found in xanthine. Two other compounds also showed activity and were probably oxidation products of uric acid. Uric acid is oxidized rapidly in this system[1], and allantoin is eluted from this column directly following uric acid.

The peak corresponding to xanthine was freed of hydrochloric acid by evaporation to dryness *in vacuo*. The radioactivity in this peak co-chromatographed with authentic xanthine in the following solvent systems which were run in a descending manner: *n*-butanol/pyridine/water (70 : 30 : 10) run for 72 hr., *n*-butanol saturated with water (64 hr.), and *n*-butanol/methyl-ethyl-ketone/triethylamine/water (20 : 20 : 2 : 10) for 64 hr. The radioactivity could not be separated from the xanthine spot by high-voltage paper electrophoresis in 0·075 *M* phosphate buffer, *p*H 7·5.

Following exposure of *Chlorella* to 8-azaguanine-2-^{14}C, a very small amount of radioactivity was detected by paper chromatography of the cell extract in the 8-azahypoxanthine spot. These chromatograms were developed in an ascending manner in 2 *N* hydrochloric acid/*iso*propanol (35 : 65)[5]. However, the chromatograms were overloaded with azaguanine and azaxanthine and a second separation in the same solvent was necessary to obtain radiochemically pure azahypoxanthine. The doubly chromatographed azahypoxanthine was eluted and further rechromatographed in butanol saturated with water and also in butanol, pyridine, water. The material was also subjected to electrophoresis in 0·05 *M* sodium bicarbonate–sodium carbonate buffer, *p*H 9·85. With both methods the radioactivity was not resolved from the ultra-violet light-absorbing spot of 8-azahypoxanthine.

In addition to the previously demonstrated oxidation of the purines in *Chlorella*[6], these results show that a mechanism also exists whereby purines are reduced. These reduced products were present in small amounts and, therefore, the steady state for these reactions must be far towards oxidation. The level of radioactivity in hypoxanthine was probably too low for unequivocal detection.

The only previous report of a reversal of xanthine oxidase is that of Whitely and Ordal[7]. However, in this case the reaction was carried out in an atmosphere of hydrogen. My results are not sufficient to exclude the possibility that the apparent reversal of xanthine oxidase took place via a nucleotide cycle such as that described recently by Magasanik and Karibian[8]. Nevertheless, it is difficult to envisage the involvement of histidine biosynthesis in the purine effect, since this effect is dependent on nitrogen starvation of the cells and takes place in the absence of any added nitrogen sources. Furthermore, the instantaneous response of respiration to added purines[1] would not suggest that there is an initial conversion of the purines to the nucleoside or nucleotide stage. It has been found in results, which will be presented elsewhere, that the substrates for the purine-stimulated respiration are the storage lipids of the cells. It is tempting to speculate that the reduction of the purines is coupled in some way to a step in the oxidation of the lipids. The resulting cycle could serve as a mechanism for a terminal electron-carrying system.

The able technical assistance of Miss Roberta J. Thomas and Mrs. Mary K. Wall and the critical discussions of Dr. I. W. F. Davidson are gratefully acknowledged.

Action of Glutamic Acid and Glutathione Analogues on the *Hydra* Glutathione-Receptor

REDUCED glutathione (GSH) is known to activate surface receptors of *Hydra*, resulting in the co-ordinated feeding reflex[1]. Loomis's demonstration that asparthione (β-aspartylcysteinylglycine) did not activate the feeding reflex suggests that the γ-glutamyl moiety is essential for the action of GSH[1]. Furthermore, the demonstration by Cliffe and Waley that ophthalmic acid (γ-glutamyl-α-amino-*n*-butyrylglycine) activated the feeding reflex shows that the sulphydryl group is not necessary for the action of GSH on *Hydra*[2]. The present work was undertaken to characterize further the structural features of the tripeptide which are necessary for the activation of the GSH-receptor. In this series of experiments we demonstrate that either glutamic acid or glutamine act as competitive inhibitors of GSH. In addition, analogues of the GSH tripeptide were found either to activate or inhibit competitively the feeding reflex, depending on the size of the group substituted for the thiol.

The activity of the feeding reflex is expressed as previously described[3], and the experiments were carried out with the following modifications: (1) only *Hydra* starved for two days were used; (2) all experiments were carried out in a solution consisting

Table 1. ACTIVATION OR INHIBITION OF THE GSH-RECEPTOR

Compound	Duration of the feeding reflex (min.)		
	Compound alone	Compound + 10^{-6} M GSH	Compound + 10^{-5} M GSH
Control, no analogue added	—	28·3	35·2
Glutamic acid 10^{-5} M	0	0·8	22 0
Glutamine 10^{-4} M	0	0	23·1
Ophthalmic acid 10^{-5} M	31 6	—	—
S-methylglutathione 10^{-5} M	29 2	—	—
Asparthione 10^{-4} M	0	0	32·7
S-Acetylglutathione 10^{-4} M	0 9*	3 3	31·1
γ-L-Glutamyl-L-sulphi-alanylglycine 10^{-4} M	0	0	15 7
Oxidized glutathione 10^{-4} M	0	2 3	23 1

* A small amount may be hydrolysed at these conditions.

of 10^{-3} M calcium chloride, 10^{-4} M sodium chloride and 10^{-3} M histidine buffer, pH 6·2.

The results (Table 1) demonstrate that 10^{-5} M glutamic acid inhibited the feeding reflex which was activated by 10^{-6} M GSH. Increasing the GSH concentration to 10^{-5} M reversed this inhibition; thus, the inhibition is thought to be competitive. Glutamine, at 10^{-4} M, also was shown to inhibit competitively. Not inhibitory were cysteine, glycine, α-ketoglutaric acid, glutaric acid, pyroglutamic acid, aspartic acid, asparagine, and glycylglycine.

Also shown in Table 1 are the actions on *Hydra* of different GSH analogues. Only two, ophthalmic acid and S-methylglutathione, activated the feeding reflex in the absence of GSH. Analogues having large substituents at the thiol position, as in the case of S-acetylglutathione, oxidized glutathione, or γ-L-glutamyl-L-sulphi-alanylglycine, did not activate the feeding reflex. In contrast, 10^{-4} M concentrations of the analogues were potent inhibitors of GSH at 10^{-6} M. These inhibitions were partially or completely overcome by increasing the GSH concentration to 10^{-5} M.

It is of interest to compare the activity of GSH analogues on two different systems requiring GSH: the enzyme glyoxalase, and the GSH-receptor of *Hydra*. Glyoxalase requires a tripeptide coenzyme which must be both similar to GSH and contain the free sulphydryl group; for example, asparthione is nearly as effective as GSH[4]. All analogues having the thiol group modified, but retaining the tripeptide structure, are competitive inhibitors (see refs. 5 and 6).

The GSH-receptor of *Hydra*, on the other hand, does not require the thiol group for activity; in this category ophthalmic acid and γ-glutamylalanylglycine[2] and S-methylglutathione (Table 1) are activators. Yet related analogues (ref. 2 and Table 1), having unusually large substituents for the thiol group, do not activate but apparently occupy the receptor site and behave as competitive inhibitors. In contrast to glyoxalase, the GSH-receptor is very sensitive to changes in the glutamyl moiety of GSH, since asparthione does not activate the GSH-receptor but acts as a competitive inhibitor. Furthermore, glutamic acid, while competing with GSH for the GSH-receptor, has no effect on glyoxalase[5].

The part played by the glycyl moiety remains obscure. Glycine alone does not seem to be tightly bound by the receptor as indicated by its failure to act as a competitive inhibitor. None the less, Loomis's demonstration that γ-glutamylcysteine does not activate the receptor[1] indicates that the glycine part of GSH is necessary.

An analysis of the data (Loomis[1], Cliffe and Waley[2], and Table 1) indicates that the GSH-receptor has a most unusual specificity when compared to other proteins reacting with GSH. It is concluded that in order to activate the GSH-receptor, the structure of the tripeptide 'backbone' must be identical to that of GSH, while the thiol group, branching off the 'backbone', can be altered within certain limits.

We wish to thank Dr. S. G. Waley and Dr. V. du Vigneaud for their generous gifts of ophthalmic acid and γ-L-glutamyl-L-sulphi-alanylglycine, and asparthione respectively. Dr. J. F. Woessner's valuable criticisms of this manuscript are appreciated.

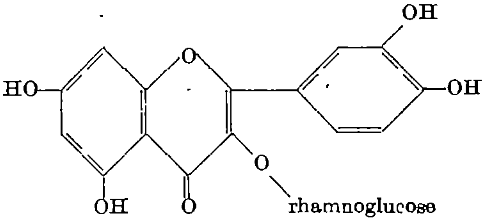
Isolation of Chromatographically Pure Rutin from Flowers of Elder

RUTIN (3-rhamnoglucoside of 5,7,3′,4′-tetrahydroxyflavanol) (I), one of the most widespread flavonoids, has been found in numerous plant materials[1,2]. On the commercial scale for pharmaceutical purposes it is usually manufactured by isolation from stalk and leaves of buck-wheat (*Fagopyrum sagittatum*)[3,4] and from the Japanese pagoda tree (*Sophora japonica*)[5]. A chemically pure preparation is then obtained by repeated recrystallization of the crude product.



(I)

Within the framework of a study of isolation of flavonoid substances from natural material it has been found that chromatographically pure rutin can be easily isolated from flowers of the elder (*Sambucus nigra*). For this purpose chromatographical partition of the extract on powdered polyamide ('Silon') material has been successfully used.

Chromatography on powdered 'Silon' has been used partly for the separation of flavonoid substances from some natural materials[6–8] and partly in their chemical analysis[9].

Dried elder flowers are extracted in a Soxhlet apparatus with 75 per cent methanol so long as the extract is green–yellow coloured. The extract is then vacuum concentrated and afterwards diluted with water in the ratio of 1 : 1. The resulting sediment of chlorophyll is filtered away, and the filtrate concentrated once more. The extract thus prepared is chromatographically purified on powdered polyamide (granulation 0·1–0·4 mm.). The size of the chromatographical column is dependent on the quantity of the extract. The polyamide powder is first allowed to swell in distilled water for about 1 hr., then the suspension is transferred to the chromatographic column and settled by gentle tapping. The concentrated extract is then passed through the column. Elution is carried out first with water and afterwards with 30 per cent methanol. The water part contains mostly the sugar ballast components ; the methanolic fraction the flavonoid substances. The course of elution is watched by means of an ultra-violet lamp, and the fraction showing a brown-green fluorescence is collected. The methanolic eluate is concentrated to a small volume and the resulting sediment of rutin filtered away and dried. By this method it is possible to obtain pure rutin from elder flowers. It has been found that the flowers contain as much as 3 per cent of rutin in the dry residue. The method described makes it possible to recover as much as 90 per cent of rutin which is chromatographically pure.

The melting point of the obtained rutin and the R_F in the solvent system *n*-butanol/acetic acid/water in the ratio 4 : 1 : 2·2 proved to be identical with those of a pure preparation. Acid hydrolysis yields quercetin; from the sugars, glucose and rhamnose in the ratio 1 : 1 have been found. Chemical analysis of the product was also in agreement with pure rutin.

This method of isolating chromatographically pure rutin from elder flowers by partition on powdered polyamide is rapid. simple and easy to carry out. The method is preferable also from the economical point of view, since a chromatographically pure preparation is obtained without any recrystallization.

Estimation of Volatile Anæsthetics in Tissues by Gas Chromatography

IN work on the uptake and elimination of volatile anæsthetics by the body, a convenient method is needed to determine their concentrations in blood, brain, liver, muscle, fat, etc. The elimination of these anæsthetics from the blood follows an exponential law. To determine the elimination curve accurately, a large number of samples has to be taken. It is desirable that the total volume of blood removed be as small as possible, and the method has, therefore, to be as sensitive as possible. This applies particularly to the last part of the curve, when the concentrations of the anæsthetic are low, for example, 10–1 p.p.m.

Conventional methods of estimating di-ethyl ether[1], chloroform and trichloroethylene[2] and halothane[3] are unsatisfactory because they require relatively large samples, lack specificity, and are time-consuming. With these methods concentrations less than 10 p.p.m. are difficult to estimate. Mass or infra-red spectrometry has a sensitivity which is less, that is, about 100 p.p.m. for detection and about 1,000 p.p.m. for estimation.

An elegant solution to the problem is the use of gas chromatography[4]. A method of utilizing the blood sample directly is being developed. At present, however, the anæsthetic is extracted from blood (or other tissue) into *n*-heptane. Using gas chromatography, it is possible to estimate halothane in *n*-heptane at concentrations less than 10 p.p.m.

The separation of *n*-heptane and the anæsthetic is achieved in a column 12 in. long. The column is made of copper refrigeration tubing, ¼ in. internal diameter, packed with 80–100 B.S. mesh 'Celite', which is impregnated with 10 per cent by weight of silicone fluid M.S. 550. The column is maintained at a steady temperature in an air oven. Hydrogen is used as the carrier gas at a flow-rate of about 45 ml./min. Extracts containing more than one substance may require a longer column, perhaps 30 in. long. The temperature of the column should be 25–30° C. for di-ethyl ether and halothane, and for substances with higher boiling points, for example, chloroform, trichloroethylene and methoxyflurane, it should be 100–120° C.

A flame ionization detector modified from that of Harley *et al.*[5] has proved suitable. Gauze electrodes, made of stainless steel, are used on either side of the flame, but not in contact with it. This type of detector appears more sensitive to halogenated compounds than the usual flame detector[6]. A potential difference of 120 V. is placed across the electrodes, and the ionization current is passed through a 1,000 megohm resistor. The resulting potential is measured with a simple balanced cathode follower unit or a vibrating reed electrometer, feeding a potentiometric recorder. Each sample is introduced into the column with a

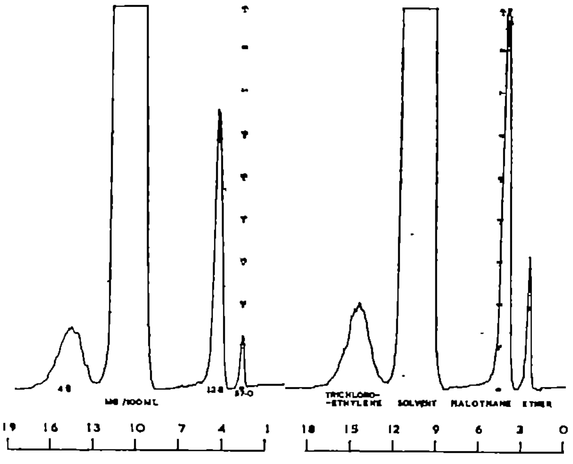

FIG. 1. Chromatogram showing di-ethyl ether, halothane and trichloroethylene after their extraction from blood with *n*-heptane. 'Celite'–silicone column at 30° C. ; carrier gas at 45 ml. per min. ; 12 in. chart at ⅓ in. per min. The approximate concentrations are shown beneath the peaks. On the second run (left) the gain was reduced so that the halothane peak could be estimated

capillary pipette[7], delivering 0·15–0·50 µl. The technique for introducing the sample is carefully standardized.

Using this method, halothane can be measured at a concentration of about 10 p.p.m. and a calibration curve had a coefficient of variation of 0·68 per cent. When the peaks on the chromatogram are narrow, their heights rather than their areas may be used for making standard curves. Fig. 1 illustrates the ability of the method to separate and detect different anæsthetics which had been extracted from one sample of blood.

We wish to acknowledge the encouragement of Prof. R. F. Woolmer in this work, and the financial support of the Sir Halley Stewart Trust.

3-Aminomethylindole and 3-Methylaminomethylindole: New Constituents of Barley

THIS communication reports the identification of two new alkaloids, related structurally and perhaps biosynthetically to gramine. Shoots of 4-day-old barley seedlings were extracted with trichloracetic acid. The centrifuged solution was extracted with ethyl ether, made alkaline and re-extracted. The ether extract of the alkaline solution was dried and concentrated. Aliquots were chromatographed using paper impregnated with a mixture of 0·2 *M* dipotassium hydrogen phosphate and 0·03 volume of 0·1 *M* citric acid[1] and developed with *iso*propanol equilibrated with 0·29 volume of the same buffer. Sprayed with Millon's reagent[1], the chromatograms showed a strong gramine spot, and two spots called here compounds *A* and *B* and identified by the evidence below as 3-aminomethylindole and 3-methylaminomethylindole respectively. In addition, there was an unidentified spot.

The rate of movement of compound *A* relative to that of gramine (R_{Gramine}) is approximately 0·66. It reacts with Millon's reagent to form a yellow-brown spot which gradually acquires a reddish hue, gives a yellow spot with ninhydrin, but no colour with either the benzoquinone or the nitroprusside reagents used to detect secondary amines[2]. Eluted from a paper chromatogram and dissolved in dilute hydrochloric acid, this material displayed a distinctive ultra-violet absorption spectrum in all respects similar to the spectra of authentic 3-aminomethylindole and gramine.

In the presence of compound *A* and of methyl-^{14}C-(–)-S-adenosyl-L-methionine, an enzyme preparation from barley shoots forms a new radioactive compound (R_{Gramine} = 0·76). The reaction is dependent on compound *A*. This radioactive compound on treatment with excess methyl iodide in ethanol gives rise to further radioactive spots which were identified chromatographically as gramine and tetramethylammonium salt, and to material(s) which move with an R_{Gramine} of approximately 1·19. These results are entirely compatible with the postulate that compound *A* (3-aminomethylindole) is converted (enzymatically) to 3-methylaminomethylindole. The latter, on treatment with methyl iodide, is changed to gramine, the methyl moiety of which in the presence of methyl iodide is known to be recovered both in tetramethyl-ammonium ion and in other compounds[3].

Authentic 3-aminomethylindole, prepared essentially by Putochin's method[4], displays properties similar to those of compound *A* in all these particulars.

Compound *B* moves with an R_{Gramine} of 0·76, reacts with Millon's reagent to give a final colour intermediate between those of compound *A* and gramine, gives no colour with ninhydrin, but reacts as a secondary amine with the sprays mentioned previously. After elution from a preparative chromatogram, compound *B* has an ultra-violet spectrum in dilute hydrochloric acid similar to that of gramine. Naturally occurring compound *B* is indistinguishable from the compound formed by the enzymatic or (in poor yield) chemical methylation of 3-aminomethylindole. It was further shown that an enzyme obtained from barley shoots forms radioactive gramine when incubated with methyl-^{14}C-(–)-S-adenosyl-L-methionine, this reaction being dependent on the addition of compound *B*.

Taken together, these findings establish the identity of compound *A* with 3-aminomethylindole and of compound *B* with 3-methylaminomethylindole.

Work on the metabolism of these substances is continuing, and will be reported on fully. At present it may be suggested that gramine is formed physiologically by the enzymatic transfer of methyl groups from (–)-S-adenosyl-L-methionine to 3-aminomethylindole to form successively 3-methylaminomethylindole and gramine.

PHYSIOLOGY

Local Treatment of Experimental Burns with a Monoamine Oxidase Inhibitor

PREVIOUS work has shown that prior systemic administration of inhibitors of the enzyme monoamine oxidase led to striking diminution of the increased capillary permeability that followed thermal and chemical injury in rats[1]. Similar anti-inflammatory properties have been reported independently[2]. This effect may be due to the preservation of an adrenaline-like substance the destruction of which by monoamine oxidase might permit the full development of the inflammatory reaction. The present investigation was undertaken to determine whether monamine oxidase inhibitors would reduce inflammatory œdema when applied locally after thermal injury.

Standard thermal injury, in this case 60° for 27 sec., was produced in anæsthetized rats by methods previously published[3]. The monoamine oxidase inhibitor employed was (2-4′-hydroxyphenoxyethyl) hydrazinium chloride (compound 1273, Smith and Nephew Research, Ltd.). The substance was made up as a 5 per cent ointment in a 'Carbowax' base (polyethylene glycol 400, 60 per cent; polyethylene glycol 4,000, 35 per cent). The ointment was applied immediately after completion of the period of thermal injury. It was rubbed in gently but liberally and continuously for 15–20 min., the animals then being returned to their cage. Three hours after thermal injury the rats were killed and the burnt area excised for the assay of inflammatory œdema as described previously[3]. Control rats consisted of untreated animals and of animals treated identically, but with the ointment base alone.

The results were expressed as gm. water/cm.^{2} skin, and are set out in Table 1. In order that the figures given should truly represent inflammatory œdema, the normal water content of skin (0·03 gm./cm.^{2}) was deducted from each set of figures before setting out the table.

Table 1. Effect of Monoamine Oxidase Inhibitor Ointment on Œdema after Standard Thermal Injury

Treatment	No. of animals	Mean value water content of burnt area (gm./cm.^{2})	Range of values (gm./cm.^{2})	P
None	12	0·21	0·13–0·35	—
Compound 1273 ointment	10	0·09	0·09–0·10	< 0·001
Ointment base only	6	0·22	0·13–0·35	—

It can be seen that thermal injury of this intensity led to a very considerable œdema of skin and subcutaneous tissues. It is equally apparent that application of the ointment containing compound 1273 led to a striking diminution of this increased capillary permeability, whereas similar use of the ointment base alone failed to do so.

It is reasonable to suppose that monoamine oxidase inhibitors have a similar effect when administered locally as an ointment or systemically, that is, by preventing the inactivation of an endogenous adrenaline-like substance the action of which is to diminish capillary permeability to protein[4].

This hypothesis is supported by the inhibition of inflammatory œdema that results from the subcutaneous injection of adrenaline (0·5 mgm./kgm.) up to 30 min. after standard thermal injury (Spector and Willoughby, unpublished observation). On the other hand, intravenous injection of monoamine oxidase inhibitors after thermal injury failed to diminish increased capillary permeability. If ointment and injection operate on similar endogenous mechanisms the discrepancy between their effectiveness after thermal injury must be presumed to be due to better access to the affected tissues by the locally applied substance. Again, if ointment and prior injection work in similar fashion, the present experiments provide further evidence to indicate that, as suggested previously[4], release and destruction of the adrenaline-like substance is a local phenomenon at the site of injury.

We thank Messrs. Smith and Nephew Research, Ltd., for their co-operation, and Sir Roy Cameron for his interest in the investigation.

Augmentation of the Pressor Response to Guanethedine by Inhibition of Catechol O-Methyltransferase

Intravenous administration of guanethedine has been reported to cause a pressor response[1,2], contraction of the nictitating membrane of the cat and pilo-erection[2]; the pressor response was not blocked by ganglionic blocking agents[2]. These phenomena lead to the possible conclusion that guanethedine causes a release of catecholamines or has some direct adrenergic effects.

The catecholamines are biochemically inactivated by the enzyme catechol O-methyltransferase[3] and this enzyme is inhibited under both *in vivo* and *in vitro* conditions by various polyphenols[4] which compete with the catecholamines for the enzyme[5]. The results of Wylie *et al.*[6] showed that the effects of both endogenous and exogenous catecholamines could be prolonged by administration of the catechol O-methyltransferase inhibitor pyrogallol; this type of agent, therefore, provides a specific tool for the pharmacological determination of the release of catecholamines.

In the following experiments spinal cats were used, and the blood pressure was determined by cannulation of the carotid artery. In all experiments responses to *l*-adrenaline, *l*-noradrenaline and guanethedine were obtained before and after pyrogallol. The doses of all substances are given as base. The areas of the pressor responses were measured in cm.^{2} by means of a planimeter.

In the first series of experiments on 6 cats the average response to a total of 15 injections of 200 μgm./kgm. of guanethedine was 1·68 ± 0·19 (*S.E.*) cm.^{2}. Two min. after administration of 4 mgm./kgm. of pyrogallol to each of the 6 cats, the average response to the standard dose of guanethedine was 5·09 ± 0·26 cm.^{2}, and 15 min. later was 3·87 ± 0·19 cm.^{2}. The average response to a third injection 32 min. after administration of the pyrogallol was 2·12 ± 0·21 cm.^{2}. Thus the pyrogallol markedly augmented the pressor response to guanethedine, and as shown in previous work[6] this action of pyrogallol lasted for about 30 min. In none of these experiments did this dose of guanethedine produce a preliminary hypotension as reported by others[1,2].

Many substances have been reported to release catecholamines from the adrenal glands. In 3 cats the effects of guanethedine alone and immediately following pyrogallol were measured before and after acute bilateral adrenalectomy. In all cats removal of the glands reduced the blood pressure by about 20 mm. mercury; but the responses to guanethedine

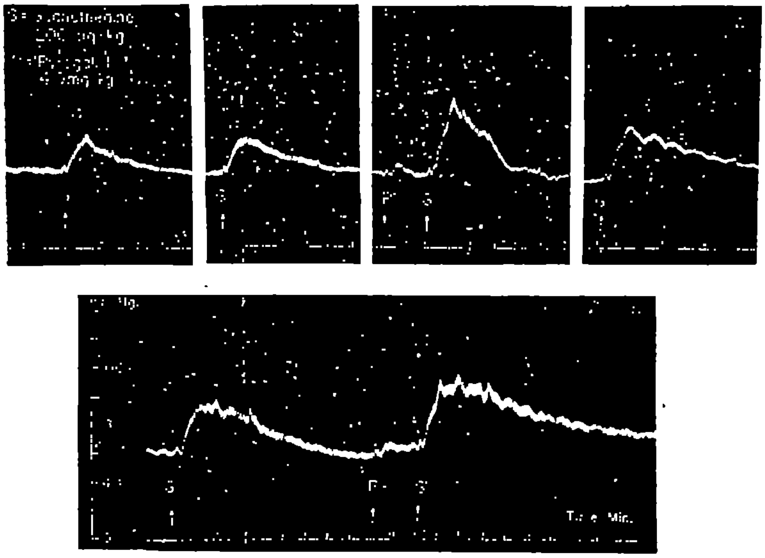

Fig 1. Pressor responses to guanethedine (*G*) and pyrogallol (*P*) plus guanethedine, before and after bilateral adrenalectomy between tracings *A* and *B*

were similar to those before adrenalectomy and could still be augmented by pyrogallol. The tracing obtained during one of these experiments is shown in Fig. 1.

It would therefore appear from the results given here that guanethedine causes a pressor response by the indirect mechanism of releasing catecholamines as this response is augmented by prior administration of pyrogallol, a known catechol O-methyltransferase inhibitor. As the pressor response is not diminished by ganglionic blocking agents[4] and is not much affected by bilateral adrenalectomy, it becomes more probable that guanethedine liberates catecholamines from the sympathetic nerve endings. Such a mechanism of action would explain the sympathetic atony reported by Maxwell *et al.*[2] to follow several hours after medication.

I am grateful to Mrs. M. Hart for assistance.

Rate of Evaporation from Different Regions of the Skin of Indian Zebu Cattle

Indian zebu cattle differ from the cattle of the temperate regions in having a marked hump and voluminous dewlap and navel flap. These structures are specially well developed in areas with very oppressive summer heat, and it has been suggested that these special structures may be related to the animal's greater thermoregulatory power.

The distribution of sweat glands has been studied in the dorsal and ventral skin and in hump, dewlap and navel flap. The secreting surface area of a single sweat gland is not significantly higher in the hump, but the effective secreting surface per sq. cm. of skin surface is much higher owing to a very high concentration of sweat glands[1].

An attempt has been made to study the physiological function or the activity of the sweat glands by determining the evaporation of sweat from different cutaneous surfaces by Berman's method[2]. Cobalt chloride anhydride paper disks (28·3 sq. mm.) were applied on different areas of the body and the time for the complete change of colour noted at an ambient temperature of 38° C. and 74 per cent relative humidity. The average time taken for the dorsal trunk to decolorize the disks was 3 min. 17 sec., and taking this as the standard 100 per cent evaporation, the relative evaporation-rate from other areas was 149 per cent on the hump and 124 per cent on the neck; but the rate on the abdomen was only 72 per cent and on the dewlap and sheath was only 58 per cent. Thus the hump has developed special thermoregulatory significance in the tropical zebu cattle. These findings also confirm the work on the Brahman cattle[3].

We are indebted to I.C.A.R. for grants-in-aid to defray the expenses of the investigation and to Lieut.-Colonel J. M. Lahiri, director of veterinary services and animal husbandry, West Bengal, and to Principal K. C. Kukherjee for their interest and advice.

Inability of Refined Corn Oil to influence Spontaneous Arteriosclerosis of Old Hens

According to a large number of reports, vegetable oils (such as corn, cotton-seed, rape-seed, safflower oil, etc.) are able to decrease serum cholesterol both in man and experimental animals. Some evidence exists that this effect is, at least partly, related to the presence of highly unsaturated fatty acids such as linoleic acid. It is not clear, however, whether such vegetable oils also have beneficial effects on arteriosclerotic lesions. After cholesterol-feeding, conflicting results have been reported with rabbits as well as with cockerels. Experimental arteriosclerosis due to cholesterol-feeding may, however, be different from arteriosclerosis in man. Probably the spontaneous arteriosclerotic lesions in old birds, for example hens[1], are more like human arteriosclerosis.

Table 1. INFLUENCE OF CORN OIL FEEDING ON SPONTANEOUS ARTHRIOSCLEROSIS IN THE AORTA OF OLD HENS (AVERAGE ± MEAN ERROR)

§ Liebermann–Burchard reaction with digitonin-precipitable substances of unsaponifiable material.

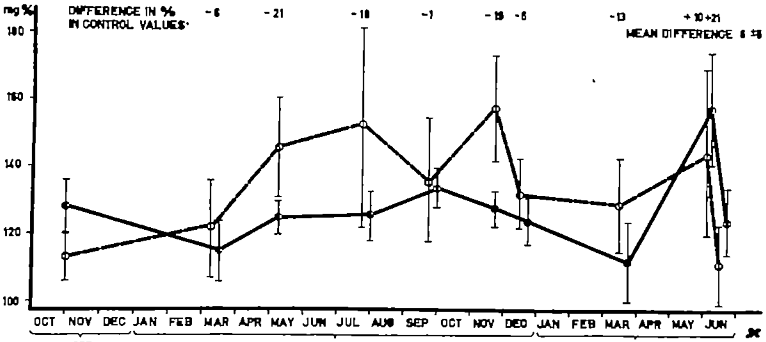

Fig. 1. Influence of dietary corn oil on serum cholesterol (ref. 5) in old arteriosclerotic hens. Points represent average values, vertical lines indicate error. – – –, Controls; ——, corn oil group

We have therefore investigated the effect of dietary corn oil on spontaneous arteriosclerosis of old hens.

Partridge-coloured Italian hens of about two and a half years were fed for 20 months a mash containing 5 per cent corn oil or 5 per cent highly saturated fats respectively. At the beginning of the experiment, randomly selected animals showed fewer aortic lesions than controls at the end of the experiment. Thus the influence of corn oil on existing and progressing arteriosclerosis was investigated.

Diet of controls: 3·0 per cent lard and 2·0 per cent coconut fat (= about 11 per cent of total calories); 6·3 per cent de-skimmed milk powder; 9·3 per cent meat powder; 8·9 per cent yeast; 3·5 per cent hay powder; 24·7 per cent rolled oats; 20·5 per cent wheat grains; 20·8 per cent wheat, rough-ground; 0·9 per cent sodium chloride; 0·1 per cent ferric citrate; 0·01 per cent manganese sulphate.

Number of animals at the end of experiment: 8 (4 animals lost in the course of the experiment because of 'diphtheria', peritonitis, tumour, etc., are not considered). Average body-weight: 1·79 kgm. at the beginning, 2·04 kgm. at the end ($\Delta = +0·29$ kgm.).

Diet of corn oil animals: 5·0 per cent corn oil (refined, edible, winterized quality, E. F. Drew and Co., Inc., Bonnton, New Jersey; content of linoleic acid 54·2 per cent, peroxide number 3·85 (analysis by Dr. J. Hofstetter, F. Hoffmann–La Roche and Co., Ltd., Basle) instead of lard and coconut fat.

Number of animals at the end of experiment: 10 (3 lost by similar diseases as controls were not considered). Average body-weight: 1·67 kgm. at the beginning, 2·03 kgm. at the end ($\Delta = +0·39$ kgm.).

Fig. 1 shows that dietary corn oil failed to diminish total serum cholesterol. Although in the corn oil group a tendency to decreased levels was obvious, the differences from controls were not significant ($P > 0·05$). This finding is in agreement with observations in mature cockerels[2] and growing chicken[3], the serum cholesterol of which was not decreased by oils rich in highly unsaturated fatty acids.

In fowls, the degree of cholesteræmia does not necessarily parallel that of spontaneous arteriosclerosis[4]. Therefore the condition of the arterial tissue itself is of more interest. In the present experiments, however, visible lesions as well as total lipids and cholesterol of the aorta were also not influenced significantly by the corn oil diet ($P > 0·05$) (Table 1).

Thus, in a long feeding period, 'physiological' amounts of refined edible oil (containing 54 per cent of linoleic acid) failed to diminish spontaneous arteriosclerosis of the aorta in old hens.

The conflicting results with cholesterol-fed rabbits and cockerels, as well as the present negative findings in old hens, do not support the assumption that linoleic acid of vegetable oils has beneficial effects on the development of arteriosclerosis. It remains, however, to be shown whether a higher percentage of corn oil in the diet is needed, or whether hens do not respond like mammals. Before these possibilities are excluded, definite conclusions regarding human arteriosclerosis cannot be drawn.

Addendum. Since submission of this manuscript, it has been reported that even a double amount of corn oil in the diet (10 per cent) fed to Leghorn pullets for the following three years did not affect the development of spontaneous lesions of the abdominal aorta in comparison with controls receiving animal tallow[7].

Effects of Pulped Soybean Silage on the Milk-yield of Cows

As a result of co-operative investigations carried out with the Research Institute for Animal Physiology, a report has already been published[1] on the summer feeding of green soybeans, in which it was shown that the relative protein-deficiency in green maize silage having a high dry-matter yield may be compensated by the flowering, pod-forming soybean. In the present communication we propose to describe our experimental results on the feeding of silage

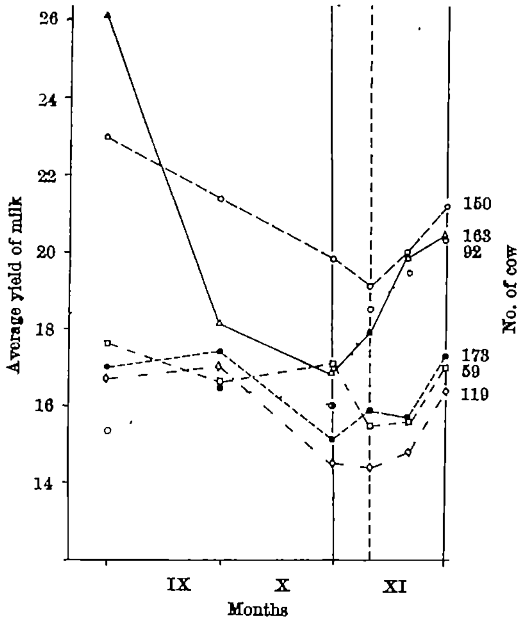

Fig. 1. Milk-production curve during feeding with soybean silage

made from soybeans pulped in the green condition. The analytical results showed that the digestible protein content and starch value of 1 kgm. of wheat bran are equal to the digestible protein content and starch value of 5 kgm. pulped soybean silage. We endeavoured, therefore, to demonstrate in our feeding experiments with pulped soybeans whether from the point of view of food conversion wheat bran can be substituted by soybean-silage.

The wheat bran fed in the preparative and first phase of the experiment was gradually substituted by soybean silage, as shown in Table 1.

Table 1

Experimental phase	Days	Quantity of food fed daily (kgm.)					
		Alfalfa	Best	Chaff	Bran	Maize meal	Soybean silage
Preparative	5	7	15	4	3	2	—
Phase I	5	8	15	3	3	2	—
,, II	5	8	15	3	2	2	5
,, III	5	8	15	3	1	2	10
,, IV	10	8	15	3	—	2	15
Concluding	5	7	15	4	3	2	—

Table 2

Experimental phase	Daily average milk production	Increase in yield in relation to the preparative phase	Relative growth of butterfat (per cent)
Preparative phase	16·2	—	—
Phase I	16·9	0·7	0·1
Phase II	17 3	1·1	0·2
,, III	17·5	1 3	0·2
,, IV	18·8	2 6	0·3

Table 2 shows that there was a considerable increase in the daily average milk production compared with the average shown during the preparative period.

The increased average yield of milk and of its percentage of butterfat contents indicate that soybean-silage is not only a substitute for the wheat bran, but also, due to its stimulating action on milk production, is from the biological and physiological aspects a far more valuable food than wheat bran, although both have the same nutritional value. Indeed, the food conversion value of soybean silage, taking wheat bran as 100 per cent, is 116 per cent. The effect on the lactation curve of feeding soybean silage is illustrated in Fig. 1. We believe that the break in the course of the lactation curve, when it turns upwards, should be interpreted as a hormone effect. Among the large number of physiologically active substances occurring in the soybean only a few may be mentioned the role of which is presumably not negligible: hæmatin, α-lipoic acid, vitamin E (tocopherol), vitamin K (α-phylloquinone), vitamin B_6 (adermin), pantothenic acid, stigmasterin, sitosterin, campesterin, ergosterin, sapogenol(s), etc. (Karrer[2]). According to Magee and Matrone[3], the œstrogen-like effect of green soybeans stimulates the development of the uterus in mice, and we believe a part is played by the high sterin content of the soybean. The increase of the butterfat content during feeding with soybean silage is equally indicative of the functional activity of acetyl-coenzyme *A* and may perhaps be connected with the relatively high acetyl-coenzyme *A* content of the soybean. It is noteworthy that the relatively high palmitic acid content of soybean oil, and easier linkage of the palmitic acid into the fatty acid cycle, may be, according to Green[4], related to the increased percentage of butterfat during feeding with soybean silage.

Antiaccelerator Action of Methoxamine

In 1949 it was demonstrated by Otto Krayer[1] that the heart-rate-increasing action of adrenaline could be selectively antagonized by veratramine through a direct inhibitory action on the pacemaker of the heart. Since then it has become established that secondary amine bases of steroid nature among veratrum alkaloids all share this property in common and the term 'anti-accelerator' was given to this property[2]. More recently this property has been recognized as occurring in several types of compounds other than veratrum alkaloids[3,4].

In the course of the systematic investigations of the cardiac action of β-hydroxy-β-(2,5-dimethoxyphenyl)-*iso*propylamine (methoxamine), a synthetic sympathomimetic amine, it was found that in certain concentrations this compound also was capable of antagonizing the cardioaccelerator action of adrenaline, while it produced itself almost no change in the heart-rate. As such a property in a sympathomimetic amine is very interesting because it may provide an important clue to the better understanding of the basic mechanism of the action of the sympathomimetic amines upon the heart, we wish to report the findings briefly. The full account will be published elsewhere in the near future.

The effect can best be demonstrated in the isolated atropinized mammalian heart. We used the heart—

lung preparation of the dog and performed the following two types of experiments.

(1) *Modification of the chronotropic effect of single doses of adrenaline.* When 2–5 µgm. of adrenaline was injected in the heart–lung preparation of the dog, the heart-rate increased considerably to reach a peak in 20 sec. or so and then gradually decreased to the initial level. A second injection proved to be as effective as the first one in its cardioaccelerator action; the same degree of increase in the heart rate occurred and the time course was practically unchanged. However, after administration of 10–20 mgm. of methoxamine, the heart became less sensitive towards the cardioaccelerator action of adrenaline. In a typical experiment administration of 2 µgm. of adrenaline increased the heart-rate from 103 to 157 (increase of 54 per cent). 8 min. after 20 mgm. of methoxamine, the same dose of adrenaline increased the heart-rate from 113 to 121 (increase of only 7 per cent). Later, the effect continued undiminished, and 30 min. after methoxamine the increase in the heart-rate was 118 to 124 (increase of 5 per cent).

(2) *Effect of methoxamine on the cardioaccelerator action of continuous adrenaline infusion.* When adrenaline was administered continuously at a rate of 2–4 µgm. per min. in the heart–lung preparation of the dog, the heart-rate increased gradually to a steady level, its height depending on the rate of administration. Once a steady level was reached, the heart-rate decreased little over a period of as long as 3 hr. When methoxamine was given, in doses of 1·0–100 mgm., to a heart–lung preparation with an augmented heart-rate due to continuous infusion of adrenaline, a decrease in the heart-rate occurred; 1·0 mgm. showed a noticeable, 5 mgm. a marked, decrease; 20 mgm. reduced the acceleration by about 50 per cent and 100 mgm. caused a decrease almost to the initial value (Fig. 1). The steepest fall in the heart-rate occurred during the first 2 or 3 min.; but some further deceleration usually proceeded over a period of subsequent 5–10 min., until a new level was reached. There is a quantitative relationship between the dose of methoxamine and the degree of deceleration. The dose of methoxamine causing 50 per cent inhibition of acceleration was 20 mgm. or thereabouts, a value which makes the anti-accelerator potency of methoxamine approximately one-hundredth of that of veratramine. The nature of this antagonism seems to be competitive, for, even at a time when a certain infusion-rate of adrenaline could no longer increase the heart-rate as the result of inhibitory action of methoxamine, a sufficiently high concentration still was able to give full scope to its characteristic positive chronotropic effect. Thus ten times as much as the initial infusion-rate of adrenaline readily overcame the reduced sensitivity of the heart and led to a very marked increase in the heart-rate (Fig. 1).

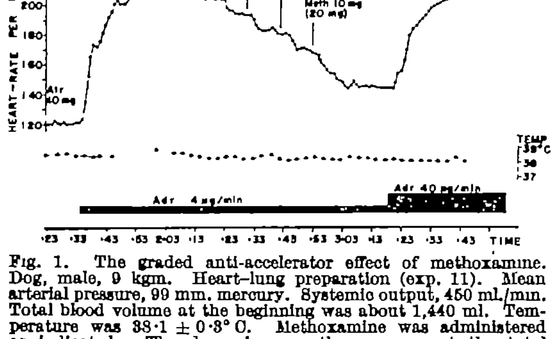

Fig. 1. The graded anti-accelerator effect of methoxamine. Dog, male, 9 kgm. Heart–lung preparation (exp. 11). Mean arterial pressure, 99 mm. mercury. Systemic output, 450 ml./min. Total blood volume at the beginning was about 1,440 ml. Temperature was 38·1 ± 0·3° C. Methoxamine was administered as indicated. The doses in parentheses represent the total amount of methoxamine administered up to the time of the respective signals

Since these actions were observed in the isolated atropinized heart, there is no doubt that they arose from the direct action of this compound on the heart muscle. A recent report from our laboratory has shown that methoxamine reduced the oxygen consumption of the isolated perfused dog heart[5]. Dealing with the protecting action of methoxamine against the toxic effect of X-ray irradiation, Smith *et al.* in their discussion[6] have suggested the reduction of metabolic-rate as the possible cause of the protection. If methoxamine has an inhibitory action on the tissue metabolism as these results imply, such an inhibition of metabolism could be the cause of the above-mentioned antagonism of methoxamine to adrenaline.

Uptake of Small Resin Particles by the Alimentary Canal of the Calf

The demonstration by Payne, Sansom, Garner, Thomson and Miles[1] that small resin particles can penetrate the wall of the alimentary tract of the calf is clear, but their claim that similar processes may be of nutritional significance is open to doubt.

The highest concentrations of particles detected were in lymph nodes and were all less than $2 \cdot 5 \times 10^3$ c.p.m./10 gm. Even if so high a concentration had been found throughout all the tissues of the animal, the recovery of the radioactivity from an animal weighing 50 kgm. would have been only just a little more than a two-thousandth of the dose administered. As the lymphatic tissue forms a trivial fraction of the body, as muscle, which constitutes about half the body-weight, had approximately one-fiftieth of the activity of the most active lymphatic tissue, and as most other tissues had activities of the order of one-tenth of the maximal lymphatic activity, one may conclude that not more than a thirty-thousandth of the dose lodged in the tissues.

If this represents the fraction traversing the wall of the alimentary tract, such traversal is clearly an improbable event. As such, it may still be important as a route of infection. But it seems very unlikely that a similar process could be of nutritional significance.

[1] Payne, J. M., Sansom, B. F., Garner, R. J., Thomson, A. R., and Miles, B. J., *Nature*, **188**, 586 (1960).

WE are grateful to Prof. R. B. Fisher for his comments but must point out that no claim was made that "similar processes may be of nutritional significance". We presume the sentence under question is: "We suggest that the use of radioactive particles of this kind may prove to be a sensitive method for the study of various problems of infectious disease and possibly also in work on nutrition and nutritional allergy"; but this can scarcely be taken as implying that the absorption of particles is of nutritional significance.

It seemed to us that the demonstration of particulate absorption, however small, might be of interest to those working on the absorption of relatively insoluble elements required in only trace amounts. In this connexion it may be of interest to record that we are endeavouring to determine the relative uptake of particles of different sizes. Experiments of this kind, attempting to measure the 'porosity' of the alimentary canal, may well find some application in work on nutrition although we are mainly interested in the pathogenesis of infectious disease.

HÆMATOLOGY

Antigenicity of A_2 Hæmoglobin

THE heterogeneity of adult human hæmoglobin is a well-established fact[1-3]. The present work was designed to determine if the slow electrophoretic fraction A_2 has antigenic specificity and if this fraction can be detected immunologically in cord blood and in the presence of hæmoglobin S and C. Previously described[4] techniques were used for the preparation and the agar-gel electrophoresis of the hæmolysates. Following electrophoresis the agar gel was cut into sections containing the hæmoglobin fractions to be tested for antigenicity. These sections were then frozen, thawed and filtered through fritted Büchner funnels of medium porosity. The short duration (90 min.) and the use of large glass plates as the base of the agar gel made it possible to obtain quantities of eluates sufficient for immunization of rabbits. Eluates of the following fractions were used for this purpose: the main component (A_1) of normal blood and of blood from a patient with thalassæmia minor; the respective A_2 fraction and the non-hæmoglobin fraction which we have previously[4] designated 'unidentified component 1' and which probably is identical with Derrien's X_1 fraction[2]. In addition the most cathodic part of the fœtal hæmoglobin from cord blood (Fig. 1*b*, area between brackets) was eluted from agar gel because of the possibility that this part contains A_2 hæmoglobin. Each eluate containing approximately 3 mgm. of protein was combined with an equal volume of Freund's adjuvant and injected into adult male albino rabbits on three or four different sites.

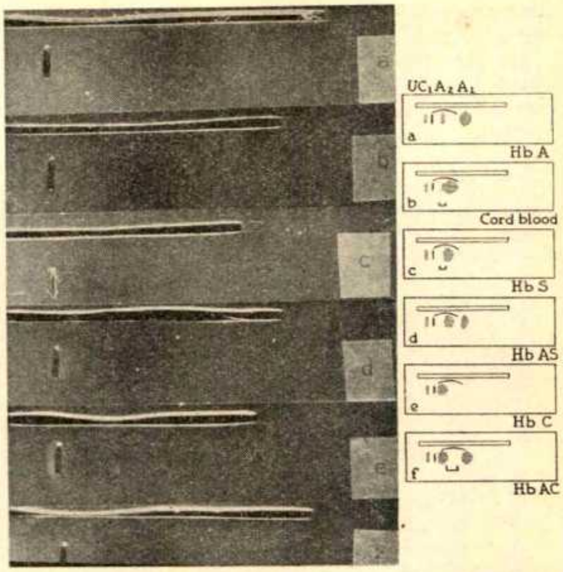

Fig. 1. Immuno-electrophoretic precipitin reaction of A_2-antiserum and hæmolysates. The brackets in *b*, *c*, *f* indicate the areas which were isolated and eluted for immunological studies

Twenty-one days following the injection blood was obtained from the ear artery and this procedure was repeated at weekly intervals. Serum from these samples was tested for antibody content by applying the Ouchterlony agar-gel diffusion technique as modified in this Laboratory[5] and immuno-electrophoresis in agar gel on microscope slides. As test antigens the following material was used: (*a*) agar-gel eluate of the A_1, A_2 and unidentified component 1 fractions of normal and thalassæmic hæmoglobin; (*b*) whole hæmolysates of normal adult and cord blood and of blood from patients with thalassæmia minor, sickle cell anæmia, sickle cell thalassæmia, A–S and A–C hæmoglobin; (*c*) eluates of sections of electrophoretograms of fœtal, S, and A–C hæmoglobin which correspond to the location of the A_2 fraction (Fig. 1*b*, *c*, *f*, areas between brackets).

Antibody to A_2 hæmoglobin appeared three weeks after a single injection of the A_2 fraction. This antibody reacted with hæmolysates of normal adult and fœtal hæmoglobin, hæmoglobin S, A–S, A–C (Fig. 1) and S thalassæmia. The precipitation line was always in a position opposite to a place on the electrophoretogram corresponding to the A_2 fraction. On Ouchterlony plates all hæmolysates reacted with the antiserum, but when eluates of the isolated fractions were used as test antigens, only A_2, the slowest section of S hæmoglobin, and the eluate of the interspace of A and C reacted, which are the areas corresponding to the location of the A_2 component. Antisera to the slowest section of fœtal hæmoglobin reacted in the same manner as the antiserum to A_2 from thalassæmic and normal blood, suggesting immunological identity of these fractions.

Antibody to A_1 and to unidentified component was demonstrated only following one or two booster injections. A_1 was only weakly, but the unidentified component 1 was strongly, antigenic (Fig. 2). Anti-unidentified component 1 serum cross-reacted slightly with A_2 but not with A_1. A clearly defined precipita-

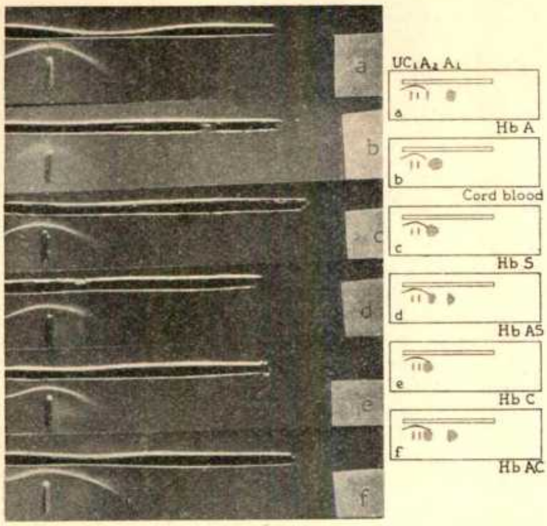

Fig. 2. Immuno-electrophoretic precipitin reaction of the unidentified component 1 antiserum and various hæmolysates

tion line was also present over the unidentified component 1 area in immuno-electrophoretograms of whole hæmolysates of normal adult, fœtal, S, A–S, C and A–C hæmoglobin (Fig. 2). With fœtal hæmoglobin (Fig. 2*b*) this line was not so strong as with the other hæmolysates. Anti-unidentified component 1 antibodies reacted slightly with γ-globulin of serum, but anti-γ-globulin did not react with the unidentified component 1.

It appears from the results of this work that A_2 hæmoglobin has specific antigenicity and that it can be immunologically demonstrated in hæmolysates of fœtal, sickle cell, and C hæmoglobin. Boivin and Hartman[6] recently reported that whole hæmolysates of fœtal, A, S, C and E hæmoglobin share at least two antigenic fractions one of which appears to be the slow component A_2. The present work lends support to this finding by the demonstration of the specific antigenicity of the isolated A_2 fraction. This finding is of interest in view of the recently detected differences in the 'finger print' between A_1 and A_2 hæmoglobin[7].

Two New Hæmoglobin Variants in a Very Young Human Embryo

IN a previous communication[1] we reported the results of a study of the hæmoglobin of 26 human fœtuses and reviewed the relevant literature. In 25 fœtuses from pregnancies of 10 weeks or more we were unable to find a major hæmoglobin component which differed from fœtal hæmoglobin (Hb–F) or adult hæmoglobin (Hb–A). In a 9-week fœtus of 3·5 cm. crown–rump length, however, the largest hæmoglobin component was found to differ from Hb–F and Hb–A ; its rate of alkali denaturation was intermediate, as also was its electrophoretic mobility in agar at *p*H 6·2, and it was assumed to be the 'embryonic' hæmoglobin of Drescher and Künzer[2]. The present communication describes the finding of two new hæmoglobin variants in a human fœtus of only 3·4 cm. crown–rump length from a 10½-week pregnancy. For convenience these will be referred to as hæmoglobins Gower 1 and Gower 2.

Approximately 0·2 ml. of blood was obtained immediately after death from the umbilical cord of the intact embryo, following therapeutic termination of pregnancy by hysterotomy, and a hæmoglobin solution prepared from the washed red cells by the method of Singer *et al.*[3]. The behaviour on alkali denaturation and electrophoresis was studied within 24 hr. of the death of the fœtus and the ultra-violet absorption spectrum was analysed later. The results were compared with those obtained on hæmolysates of blood from older fœtuses, full-term new-born infants and adults.

The rate of alkali denaturation studied by the method of Künzer[4] fell within the range given by Drescher and Künzer[2] for cord blood from full-term infants, but outside our own narrower range[1]. The proportion of alkali-resistant hæmoglobin calculated from the rate curve was 56 per cent.

On electrophoresis in agar with citrate buffer *p*H 6·2 (ref. 5) two fractions separated, one migrating similarly to an Hb–F marker and the other to an Hb–A marker.

Electrophoresis on cellulose acetate both with barbiturate buffer *p*H 8·6 and with 0·04 *M* sodium phosphate buffer *p*H 7·7 separated three main fractions plus a very small fast component. The largest fraction corresponded to Hb–F. Hb–A, which can be separated from Hb–F under the particular conditions used with barbiturate buffer, was not detected.

With starch-gel electrophoresis in *tris*-citrate/borate discontinuous buffer[6] three fractions were separated (Fig. 1). The largest corresponded to Hb–F, while the second and third were shown to move more slowly than the Hb–C and Hb–G/C respectively of a hæmolysate containing Hb–A, Hb–G, Hb–C and Hb–G/C (ref. 7). Again no Hb–A appeared to be present.

Direct spectrographic examination of the separated zones in the starch gel was carried out after the gels had been made transparent with glycerol[8]. The tryptophan fine-structure band had the following positions on the fœtal fractions :

Major zone (Hb–F)	2899–2900 Å.
Gower 1 zone	2908 ± 2 Å.
Gower 2 zone	2902 ± 2 Å.

Values obtained for Hb–A and Hb–F zones in control starch-gel analyses of hæmolysates prepared from adults and new-born infants were as follows :

Hb–F	2900 ± 1 Å.
Hb–A	2910 ± 1 Å.

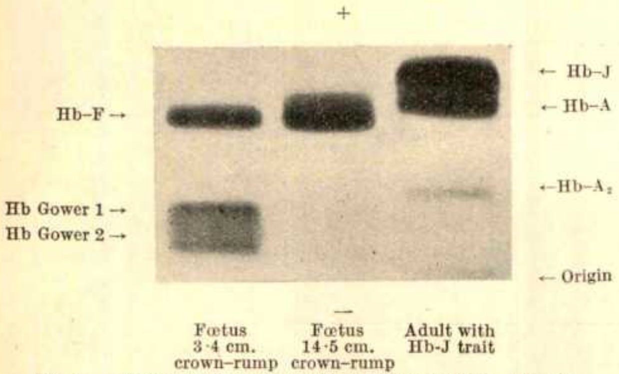

Fig. 1. Starch gel electrophoresis of hæmoglobin in the *tris*-citrate/borate discontinuous buffer system (initial gel *p*H 8·8)

The precision of the latter readings was superior as the hæmolysates were more concentrated, but the results on the fœtal blood suggest that spectrographically the hæmoglobin in the Gower 2 zone is of fœtal type whereas that in the Gower 1 zone resembles Hb–A. It should be noted that the position of the peak of the tryptophan fine-structure band for Hb–F differs from the figure of 2896–7 Å. previously reported[8,9]; this may be due to the presence of non-hæm proteins, some of which are known to migrate to the Hb–F position, as well as to background scatter contributed by the gel under the conditions used here. Non-hæm proteins may also have influenced the reading in the Gower 2 zone.

The above findings indicate that this embryo carried, in addition to Hb–F, three other hæmoglobins. The behaviour of the very minor fraction detected on cellulose acetate suggested that it could be one of the fast-moving hæmoglobins occasionally found in some cord bloods[10–12], but this hæmoglobin will not be discussed further because the minute amount of the specimen precluded adequate study. Although an appreciable fraction moved to the Hb–A position on agar electrophoresis, it could not in fact have been Hb–A because, by electrophoresis on cellulose acetate at *p*H 8·6 and on starch gel, no Hb–A was detected. Examination of the blood of both parents, who were of Jewish European stock, showed only normal hæmoglobin components by starch-gel electrophoresis and less than 2 per cent Hb–F by the 1-min. alkali denaturation procedure[3], so it is extremely unlikely that this fœtus was a carrier of a variant of Hb–A. The Gower 1 and Gower 2 fractions may be presumed, therefore, to represent variants of Hb–F or 'embryonic' hæmoglobin. Their behaviour on electrophoresis at alkaline *p*H distinguishes them from all the described Hb–F variants, for Hb–Alexandra[13] which alone moves more slowly than Hb–F differs by migrating faster than Hb–C. Neither can represent the Hb–F_I and Hb–F_{II} fractions separated by chromatography on 'Amberlite *IRC* 50' resin[14], because we have confirmed (authors' unpublished observations) that these column fractions are virtually indistinguishable from Hb–F both electrophoretically and spectrographically[15] and in their rate of alkali denaturation[15,16]. Further precise characterization of the fractions Gower 1 and Gower 2 was not possible, but our results indicate that neither can be as resistant to alkali as Hb–F and that Gower 2 is spectrographically related to Hb–F.

We think it probable that these two new hæmoglobins will rarely be seen since we have encountered them only once in the course of examining blood from 32 human fœtuses, and have not found a similar report in the literature. Moreover, we think that it may well be significant that the only two fœtuses in which we have seen hæmoglobins other than Hb–F, Hb–A and Hb–A_2 had crown–rump measurements of only 3·5 and 3·4 cm., and such small fœtuses are rarely available for study.

We wish to thank Mr. F. Ward for the photograph.

PATHOLOGY

Tumour-Promotion by Lime Oil in the Mouse Forestomach

In a recent communication[1] it was shown that four different citrus oils promoted tumour development in mouse skin after pretreatment with a sub-carcinogenic dose of 9,10-dimethyl-1,2-benzanthracene (DMBA). Since man is continuously exposed to these oils in his food, it was decided to test one of them, lime oil, both for carcinogenicity and for tumour-promoting activity in the gastro-intestinal tract of mice. Another reason was the hope of demonstrating the two-stage mechanism of carcinogenesis in the alimentary canal. Previous attempts to do this have given inconclusive results[2,3]. In the most recent of these, Berenblum and Haran gave mice a single dose of one of four polycyclic hydrocarbons followed by 3 per cent croton oil weekly for 30 weeks. All treatments were given by stomach tube, and polyethylene glycol 400 (PEG) was the solvent throughout. The appropriate control groups were included. Numerous tumours of the forestomach developed in all their groups, both test and

† One squamous carcinoma invading muscle.

control. It was not stated whether the rest of the intestinal tract was examined. No evidence for tumour-promotion by croton oil was obtained. There are three possible reasons for this: (1) The doses of the hydrocarbons used were too high. Bock and King[4] have since shown that the mouse forestomach is more sensitive than the skin to carcinogenic hydrocarbons. (2) Croton oil, in the concentration used, was carcinogenic. (3) PEG, although a suitable solvent for a single dose of a hydrocarbon[5], reduces the tumour yield when given repeatedly after such a dose[3] and is not, therefore, a suitable solvent for tumour-promoting substances.

In the following experiment some of these difficulties have been overcome; and early results indicate a definite tumour-promoting effect.

Stock female albino mice were randomly divided into 11 groups of 20. Before each treatment the mice were starved for 18 hours. A single dose of DMBA or 3,4-benzpyrene(3,4-BP) in 0·25 ml. of PEG was given by stomach tube, followed, after an interval of 3 weeks, by 40 weekly doses of 0·05 ml. of undiluted lime oil by stomach tube. At this dose-level the mice remained healthy and maintained a steady body weight of 32–35 gm. Mice which died between the fiftieth and the two hundred and eightieth day were examined *postmortem*, and half the survivors at 280 days were killed and similarly examined. Details of treatment and the results are summarized in Table 1.

Tumours of the forestomach were seen in all the groups receiving DMBA or 3,4-BP except group VI, but in the corresponding groups treated with the same doses of DMBA or 3,4-BP, followed by lime oil, many more tumours developed. The difference was most clearly shown in the groups receiving 50 μgm. 3,4-BP. Higher doses of DMBA and 3,4-BP partially obscured this effect. When only the tumours more than 3 mm. in diameter are considered the difference is obvious in all groups: only 2 were seen in the controls, but 22 in the test groups. So far, one malignant tumour has been seen in group III. It was a squamous cell carcinoma, with an area of poorly differentiated cells infiltrating the muscle in several places. In the two groups (IX and X) which received lime oil, but no DMBA or 3,4-BP, 6 tumours were seen including one of 4 mm. diameter. No tumours have been seen in the completely untreated controls, nor in a larger number of untreated mice kept for general observation. It seems that both the hydrocarbons and lime oil possess some oncogenic effect, but the yield of tumours in the groups treated with both agents considerably exceeded the sum of their separate effects. No tumours were seen in the glandular part of the stomach, or elsewhere in the alimentary canal.

These results represent half the experimental mice; the remainder are still under observation, as it is probable that more malignant tumours will develop after 40 weeks, as in similar work on the skin[6].

While the evidence for a two-stage mechanism of carcinogenesis was limited almost entirely to studies on mouse and rabbit skin it was possible to suppose that it was peculiar to the skin and not involved in the genesis of tumours in other tissues. The demonstration of a two-stage process in the mouse forestomach increases the likelihood that it is a general phenomenon. It is true that the epidermis and the epithelium of the forestomach are both of squamous type, but they differ widely in function, in environments to which they are exposed, and in their apparent liability to neoplastic change.

Man is inevitably exposed to small quantities of 3,4-BP and other carcinogens in his environment. Although the amounts may be insufficient to account for carcinogenesis, they are theoretically sufficient for initiation. Recently Roe, Salaman and Cohen[7] have postulated that cigarette smoking acts mainly as a promoter in the induction of human bronchial carcinoma. It is possible that citrus oils act in a similar way in the causation of cancer of the upper alimentary tract. The dose given in this experiment, a total of 2 ml. per mouse during 40 weeks, is approximately equivalent to 4 litres ingested by a man over 30 years, on the basis of comparative body-weight and life-span, and may not be unrealistic. However, it is impossible, at this stage, to extrapolate with any confidence from mouse to man.

I wish to thank Dr. F. J. C. Roe and Dr. M. H. Salaman for their valuable advice throughout this experiment. The expenses of this research were partly defrayed out of a block grant from the British Empire Cancer Campaign.

Acquired Porphyria in Man and Rat due to Hexachlorobenzene Intoxication

SINCE 1956, an outbreak of cutaneous porphyria involving several thousand cases has been noted in three south-eastern provinces of Turkey[1]. Affected individuals, predominantly children and adolescents, exhibit photosensitivity with hydroa æstivale, marked porphyrinuria and hepatomegaly, but no abdominal or neurological symptoms. Epidemiological studies suggested the possibility that the disease might be related to the ingestion of wheat treated with a fungicide containing hexachlorobenzene[1,2]. Since direct verification of this possibility by field investigation has not been obtained[1], and since the available toxicological information on hexachlorobenzene is conflicting[3], an attempt was made to produce hexachlorobenzene porphyria in rats.

Adult male Sprague-Dawley rats were fed *ad lib.* ground 'Purina Laboratory Chow' containing 0·2 per cent hexachlorobenzene. Urinary and fæcal excretion of porphyrins and porphyrin precursors were determined periodically[4], and tissue porphyrins[5] and liver catalase[6] were measured in rats killed while porphyric.

Of a total of 33 rats started on the experimental diet, 13 died within the first month, exhibiting terminal tremor, ataxia, weakness, and paralysis, without evidence of major disturbance in porphyrin metabolism. In the remaining 20 rats, a significant increase in urinary excretion of porphyrins and porphyrin precursors was first noted after 2 to 8 weeks of hexachlorobenzene administration (Fig. 1). Peak excretory values per 24 hr. were as follows (normal values in parentheses): δ-amino-lævulinic acid, 1·40 mgm. (0·06 mgm.[7]); porphobilinogen, 16·96 mgm. (0·01 mgm.[7]); uroporphyrin, 0·360 mgm. (trace[8]); coproporphyrin, 0·211 mgm. (0·016 mgm.[8]). Slight to moderate increases in fæcal excretion of copro- and proto-porphyrin were also noted. From 200 ml. of rat urine, 55 mgm. of crystalline porphobilinogen were obtained[9].

In rats in which hexachlorobenzene administration was discontinued shortly after these peak excretory values had been approximated, the disturbance in porphyrin metabolism was rapidly reversed with return to normal excretion values within a week. However, maintenance of high levels of porphyrin excretion by continued feeding of hexachlorobenzene for two to three weeks resulted in an apparently irreversible porphyric state, in which marked porphyrinuria continued in spite of cessation of drug administration (Fig. 1). These animals died with the neurological complications described above.

Hepatomegaly was common in porphyric rats. Histological studies revealed liver cell degeneration, most prominent around central veins, and increased size and number of Kupffer cells. Chemical analysis of liver tissue showed the following results, per 100 gm. wet tissue (normal values in parentheses): uroporphyrin, 0·4–0·5 mgm. (trace[8]); copro- and proto-porphyrin, 0·05–0·15 mgm. (0·01–0·02 mgm.[8]); porphobilinogen demonstrable[5] in aqueous extract of liver tissue. No significant reduction in liver catalase activity was found.

In the blood, concentrations of hæmoglobin, copro- and proto-porphyrin were normal, while uroporphyrin was not detectable. At autopsy, intense red fluorescence was observed in the cortex of long bones, but not in the marrow.

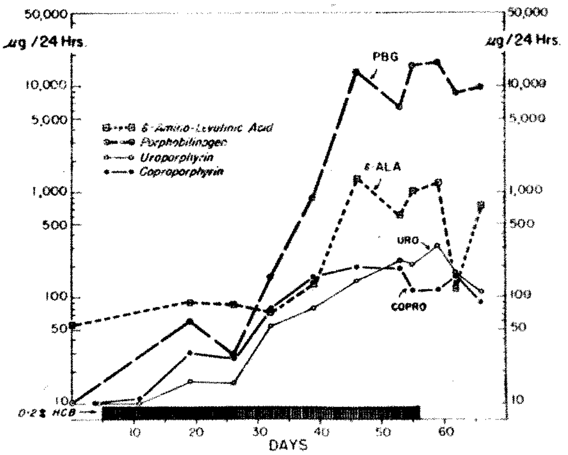

Fig. 1. Urinary excretion of porphyrins and porphyrin precursors in a 350-gm. male rat fed hexachlorobenzene. The rat died on the 68th day of the experiment, that is, 63 days after the start of the hexachlorobenzene administration and 12 days after the toxin had been withdrawn

These results demonstrate that in the rat chronic ingestion of hexachlorobenzene may indeed result in a profound disturbance in porphyrin metabolism, characterized by increased amounts of porphyrins and porphyrin precursors in the liver and excreta, with histological evidence of hepatocellular degeneration. These findings support the suggestion[1], derived on the basis of epidemiological data, that hexachlorobenzene ingestion is the cause of the recent outbreak of porphyria in Turkey. This experimental result is of particular interest in that, hitherto, human porphyria was assumed to be genetically determined, because conclusive evidence for the existence of a purely acquired form of this disease has been lacking. The widespread appearance of porphyria among three genetically distinct populations in south-eastern Turkey—domestic Turks, Kurds and Turks repatriated after several centuries of residence in the Balkans—makes its dependence on an inherited abnormality extremely unlikely.

RADIOBIOLOGY

Autoradiographical Detection of Tritium-labelled Inulin in the Kidney

By perfusion tests performed on the kidneys of rabbits which had previously been intravenously injected with inulin (100 mgm./kgm. body-weight), it has been shown that inulin was deposited in the kidney tubule cells[1]. These observations were recently confirmed by Balint and Forgacs[2]. Other authors, however, did not agree with my conclusions[3,4].

The autoradiographical detection method seemed suitable to us to obtain further information about the distribution pattern of inulin in the kidney. By means of this technique using tritium-labelled inulin we investigated the kidneys of rats and rabbits.

Alkali-stable inulin was labelled with tritium gas according to the method of Wilzbach[5] (Graul and Hundeshagen[6]). This preparation was dissolved in water and evaporated three times. The final product was obtained by crystallization from an aqueous solution with a mixture of ethanol–ether (v/v, 1/1). Its specific activity was 71·5 μc./mgm. or 286 c./mol. (assumed molecular weight: 4,000), and was alkali-resistant like the initial product. In solution the substance obtained gave a negative reduction test, and after hydrochloric hydrolysis it gave a positive Selivanoff reaction. This is sufficient guarantee that the inulin molecule had not been altered by labelling.

Five mgm. of tritiated inulin was injected under direct vision into the renal artery of an anæsthetized rabbit. After 5 min. the kidneys were removed and fixed in formalin. Transverse sections were examined by the autoradiographical method[6], using an exposure time of 2–9 months. After developing the photochemical layer, the tissue sections were stained with hæmatoxylin–eosin.

Figs. 1 and 2 represent autoradiograms obtained. Over the cells of the proximal and distal tubules there is an obvious blackening, which in other fields appears still more intense, and is even visible in some instances over the tubule lumina.

We obtained corresponding results in rats injected intravenously with tritiated inulin (50 mgm./kgm. body-weight). In these experiments the kidneys were removed after 10 and 20 min. The autoradiograms were not as intensively marked as in the above-mentioned tests, but generally a blackening over the tubule cells was clearly visible.

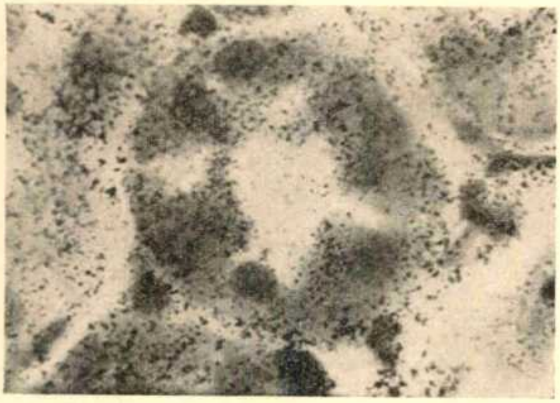

Fig. 1. Autoradiogram of a rabbit kidney 5 min. after injection of 5 mgm. tritiated inulin into the renal artery. Exposure time, 6 months. Proximal tubule. (× c. 900)

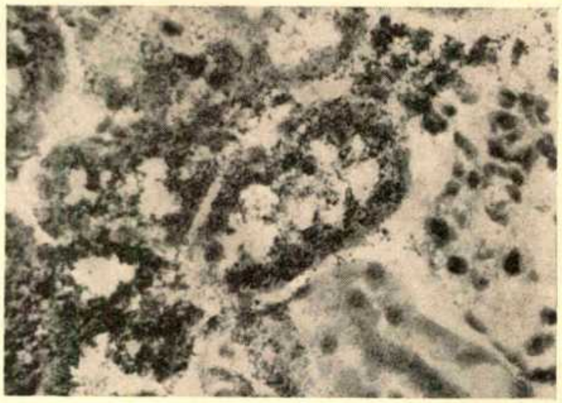

Fig. 2. Experiment similar to Fig. 1. Distal tubule, same as Fig. 1. (× c. 360)

The results of these autoradiographical investigations on kidneys with tritiated inulin confirm our opinion that inulin is deposited in the tubule cells of the kidney. No information about the mechanism of this process was obtained.

Experimental Allergic Encephalomyelitis in Irradiated Rats

Lipton and Freund[1] have produced experimental allergic encephalomyelitis in the rat by intracutaneous injection of homogenized homologous rat brain mixed with paraffin oil and tubercle bacilli. Lumsden[2] reported earlier that in the rat experimental allergic encephalomyelitis can be induced only by injecting the antigen mixture using the intracutaneous and not the subcutaneous route.

If the concept of radiation sickness as an auto-immune disease[3] is valid, then the question may be put whether it would be possible to induce experimental allergic encephalomyelitis in irradiated rats.

In the concept of auto-immune reactions of irradiated animals, which is being reported elsewhere[3], it is necessary to presume that antibody-producing cells undergo a change, that is, they mutate, thus becoming foreign to their own organism. In that manner these cells become antigenically stimulated by the organism's own cells—both normal and those which had also undergone a mutation. Antigenically stimulated cells should be radio-resistant, since immunity already acquired is not impaired by irradiation. By absorbing radiant energy, the antibody-producing cells mutate until they acquire a structure which, according to the clonal selection theory[4], corresponds to the antigens present in the body. From that moment they should behave as 'already antigenically stimulated cells', that is, they will be radio-resistant and will proliferate.

Experiments were planned so that during irradiation the reinforced brain antigen was already present in the body. The antigen was injected into experimental animals shortly prior to irradiation, with the intention that it should become attached to mutated antibody-producing cells and thus stop their further mutation and direct the immune reaction towards the recipient's own neural tissue.

Twenty albino rats were divided into two groups. The first group, consisting of ten animals, was injected subcutaneously with 2 × 0·25 ml. per animal of Freund's mixture of homologous rat brain and adjuvant; the second group of ten animals was given 4 × 0·25 ml. per animal. The amount of tubercle bacilli in the adjuvant was ten times less than prescribed by Freund in order to determine whether irradiation exerts any enhancing effect on the development of the auto-immune process. For the same reason the otherwise inadequate subcutaneous route of injection was used. The injections were given 30 min. prior to X-irradiation. The dose was 600 r. (220 kV., 15 m.amp., 0·5 copper, 1·0 aluminium, r = 40 cm. ∼ 120 r./min.). The control group consisted of ten unirradiated animals divided into two groups of five animals each and were injected with the same antigen doses and by the same route.

Results are presented in Table 1. The diagnosis of experimental allergic encephalomyelitis was based on paralysis of limbs and/or marked atactic gait. Eight out of twenty irradiated animals have shown these symptoms, which appeared between the thirteenth and the twentieth day following irradiation. Two belonged to the group which received 2 × 0·25 ml. of antigen mixture, and six to the group which was given 4 × 0·25 ml.

Table 1. INCIDENCE OF EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (EAE) IN UNIRRADIATED AND IRRADIATED RATS FOLLOWING SUBCUTANEOUS INJECTION OF ANTIGEN REINFORCED WITH ADJUVANT

Group of rats	No. of rats	No. of rats which developed symptoms of EAE
Unirradiated	10	0/10
Irradiated	20	8/20

It can be concluded that the inactivity of the immune system following irradiation is only apparent. It is supposed that radiant energy induces mutation of cells which belong to the immune system so that it becomes foreign to its own organism. The mutated antibody-producing cells might react immunologically against any antigen already present in the body and particularly against the antigen reinforced by adjuvant. In order to avoid the objection that the animals were irradiated during the inductive phase, another group consisting of 50 albino rats was injected with the antigen mixture 30 min.–24 hr. following irradiation. The incidence of experimental allergic encephalomyelitis in this group was 19 : 50.

This result favours the concept that the auto-immune processes had already started at the moment of irradiation and that antigen injection had directed it against the recipient's own neural tissue. Although this result requires further investigations, it does not invalidate essentially the concept of the auto-immune process as a cause of radiation sickness.

The beneficial effect of isologous bone marrow in the treatment of irradiation sickness might represent a serious objection to the concept of irradiation sickness as auto-immune disease. It should, however, be kept in mind that by injection of bone marrow we carry into the irradiated animal normal cells capable of antibody production.

The possibility that increased permeability of cells caused by irradiation might accelerate the contact of antigen with antibody-producing cells would mean that histamine or serotonin injection should enhance the auto-immune reaction. However, these two compounds are potent protectors against radiation damage.

Analogous experiments using other organs as antigen and changing dose and time of injection and dose of irradiation should elucidate this phenomenon and check the validity of the concept.

Distribution of Phenyl Mercuric Chloride labelled with Mercury-203, applied as a Seed Dressing, in the Tissues of the Young Carnation Plant

ORGANO-MERCURY compounds are good fungicides; they are applied to oat seeds to control *Helminthosporium* infection[1], to *Narcissus* bulbs to control *Fusarium oxysporum*[2] rot and to gladiolus corms to prevent disease caused by *Sclerotina gladioli*[3]. However, the mercury compound may damage the plant; growth of oat seedlings is less than normal when phenyl mercuric acetate is applied to the soil to protect seed[4]. Experiments described here illustrate the way in which damage to seedlings may occur when phenyl mercuric chloride is used as seed dressing to control rot in carnation seedlings.

Seeds of Annual Charm carnations were treated with varying amounts of phenyl mercuric chloride labelled with mercury-203 as follows. Groups of twenty seeds were placed in Petri dishes on wire gauze supports over a solution of phenyl mercuric chloride in dioxan (2 mgm./ml.). Control groups were exposed to dioxan vapour only or left in the dishes in the same place as experimental seeds. The amounts of dressing on the seeds were varied thus: (*a*) by exposing seeds to the vapour from the phenyl mercuric chloride solution for 24 hr. at 18° C. (Exp. 1); (*b*) by exposing them for 2–3 days at 37° C. (Exps. 2, 3); (*c*) by dipping them in the dressing solution and drying with filter paper (Exp. 4). The amount of phenyl mercuric chloride on the seeds was measured in a well-type gamma-scintillation counter which had an efficiency of *c*. 34 per cent for mercury-203. The seeds were sown in crystallizing dishes containing sterilized vermiculite, horticultural grade. They were watered with a solution containing 5 gm. urea, 5 gm. potassium dihydrogen phosphate, 2 gm. magnesium sulphate, 1 gm. ferrous sulphate and traces of manganese sulphate, calcium chloride, boric acid

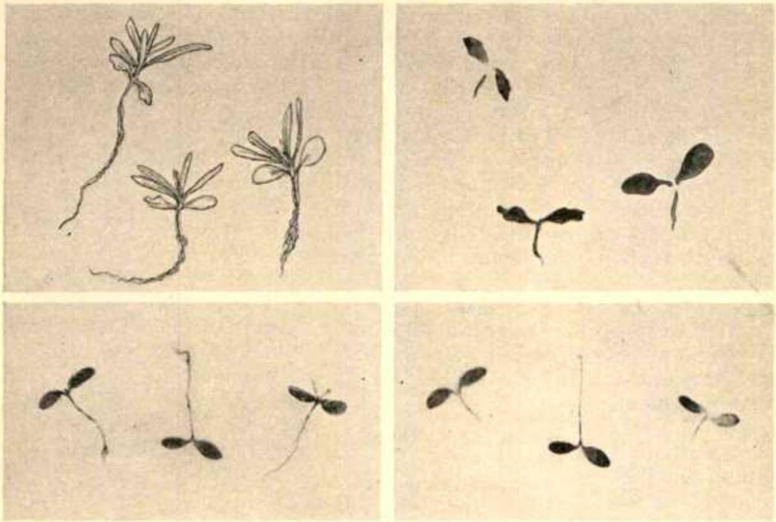

Fig. 1. Top, Exp. No. 2. Left, 8-week-old seedlings; right, autoradiograph of the seedlings to show the distribution of phenyl mercuric chloride labelled with mercury-203. Bottom, Exp. No. 3. Left, 7-week-old seedlings; right, autoradiograph to show the distribution of the labelled phenyl mercuric chloride

and sodium molybdate dissolved in 1 gal. water. The dishes were covered with polythene sheets and placed in 30° C. incubator until germination occurred. After about 3–4 weeks the seedlings were transplanted into larger enamel trays containing vermiculite and nutrient solution. The testas from germinated seeds and 4 young plants from each experiment were counted. Results are tabulated in Table 1.

The treated seedlings from Exps. 1 and 2 grew well, but in 1, one seedling had mottled cotyledons, and in 2, three seedlings had this appearance. In Exp. 3, four seedlings died early. All these failed to develop a normal root and one had mottled cotyledons. None of the control plants had damaged roots or cotyledons. In Exp. 4 the seeds received a dose of β-radiation in the range of 17–22 rads when they took 7 days to germinate. This is probably insufficient to reduce germination, since a dose of $3 \cdot 6 \times 10^3$ rads is necessary to reduce the germination of very radiosensitive seeds of *Pinus sylvestris* by 50 per cent (H. J. Bowen, private communication). However, when the seeds were treated with inactive phenyl mercuric chloride so that approximately 200 µgm. of material was deposited on the seed, germination was completely inhibited.

Young plants from experiments 1–3 aged eight or nine weeks were taken from vermiculite media washed to free the roots from particles, dried and pressed on to 'Cellophane'. They were then exposed to 'Ilfex–X-ray' film for 4–6 weeks and the film developed normally.

Table 1

Amount of activity, counts/min.		Weight (av.) of phenyl mercuric chloride/ seed (µgm.)	Testa counts/ min. (av.)	Seed-ling counts/ min. (av.)	No. of seedlings appeared	
Exp. No.	Av./seed				Treated with phenyl mercuric chloride	Dioxan control
1	978	1·92	236	284	15	16
2	1,997	3·9	330	244	13	11
3	3,663	7·23	502	1,144	14 (4 died)	11
4	95,050	186·6	no germination		—	13

In Exp. 1, 17 out of 20 untreated seeds germinated.

Fig. 1 shows the distribution of radioactivity in the plant. Phenyl mercuric chloride has concentrated strongly in the cotyledon leaves, hypocotyl and root adjacent to the hypocotyl. These plant organs appeared to be damaged in some plants in the experiments described. Some seed leaves contained phenyl mercuric chloride but were not mottled, and only a proportion of the roots which contained the compound were damaged.

An experiment was made to discover whether the smallest amount (1·92 µgm.) of phenyl mercuric chloride on the seed would prevent an infection of Dianthus seeds caused by *Trichothecium*. Seeds which had small fungal colonies on the testa were placed over phenylmercuric chloride in dioxan (2 mgm./ml.) for 24 hr. at room temperature. This treatment was the same as that in Exp. 1, which resulted in 1·92 µgm. of labelled phenyl mercuric chloride being deposited on the seed. Thirty treated seeds and untreated seeds were placed on moist tissue paper to germinate. After four days the untreated seeds were covered with mould and all failed to germinate. 75 per cent of the treated seeds germinated; only one showed mould, which was a species of *Penicillium*.

One of us (P. F.) has observed damage similar to that caused by phenyl mercuric chloride to the seedlings of carnations when seed was treated with 'Vegetable Seed Saver'. The cotyledon leaves were spotted with areas of dead tissue and growth was retarded. Occasionally seedlings failed to grow at all because no root developed. 'Vegetable Seed Saver' contains the fungicide tetra methyl thiuram disulphide (thiram). The damage caused by this and phenyl mercuric chloride is very similar with this strain of carnation.

Phenyl mercuric chloride has a strong affinity for the sulphydryl groups of protein[5]. The above results suggest that phenyl mercuric chloride has combined with protein substances in the cotyledons, hypocotyl and root, organs which are recognizable in the seed. The mercury protein was transferred from the hypocotyl to the root, but the amount in the root tip was less than that in the region nearest the hypocotyl (Fig. 1). This distribution could be explained by assuming that the mercury-protein is transferred passively during cell division and that new protein is being actively synthesized in the region of the root tip. The new protein would dilute the mercury-protein present in the dividing cell. The —SH-containing protein necessary for root growth could be derived initially from S—S protein in the cotyledons and later by synthesis from sulphate present in the growth medium. No transfer of mercury protein to the stem apex or leaves occurs although large amounts are present in the cotyledons; the reason for this is not apparent.

The similarities between the damage caused by phenyl mercuric chloride and tetra methyl thiuram disulphide may be the result of coupling with the same sulphydryl-containing compounds. Certain disulphides are known to couple selectively with —SH-containing compounds. However, a more direct comparison of the action of these fungicides on plant tissue could be made if thiram was labelled with sulphur-35. The experiments do indicate that phenyl mercuric chloride applied at the rate of 2 μgm./seed is an effective fungicide. In amounts greater than 4 μgm./seed the seedlings will be damaged, probably owing to the reduction in the quantity of SH-protein in the root and cotyledon tissues.

BIOLOGY

Species-characterizing Antigens of 'L' and 'ERK' Cells

CELL culture has become a very important procedure in both biological and medical research, and with the many continuous lines of cells available to-day it is necessary to have methods to check the identity of any given culture of cells.

With proper attention to the special needs of the problem, there must be many immunological methods that could be adapted for this purpose. Recently, we[1] have reported on the use of the mixed agglutination reaction for the recognition of the species of origin of cells in culture. In this communication we wish to report briefly our findings on two continuous lines of cells, namely, the 'L' and 'ERK' strains, using the mixed agglutination reaction and antisera apparently specific for tissue cells of the various animal species.

The histories of these two strains are as follows. The 'L' strain[2] is of mouse origin, the parent strain having been derived in 1940 from the subcutaneous and adipose tissue of a 100-day-old male mouse of the *C3H* strain Andervont sub-strain. One group of cultures from this parent strain was treated with 3-methylcholanthrene at a concentration of 2·0–2·5 μgm./ml. for 111 days, and was designated strain 'L'. The parent strain prior to this treatment was grown on a fowl plasma–embryo extract clot, with a supernatant fluid medium consisting of Earle's saline (40 per cent), horse serum (40 per cent) and fowl embryo extract (20 per cent); strain 'L' cells were cultured initially in the same way, and have since been grown as monolayers on glass under the same fluid medium for some years. The cells used here were derived from a sample provided by Dr. J. Paul, and have been grown as monolayers on glass in Eagle's medium supplemented with 10 per cent bovine serum.

The 'ERK/1' strain was derived by trypsinization of one kidney of an embryonic rabbit by Westwood *et al.*[3]; it was cultured initially on glass in roller bottles in a medium consisting of rabbit serum (10 per cent), 'TPY' supplement (5 per cent), cystein-hydrochloride (0·02 per cent) and Earle's saline (to

100 per cent) ('TPY': Tryptic meat broth, 88 per cent; peptic digest of sheep's blood, 2 per cent; yeast extract, 10 per cent). Epithelial cells grew out first, but were later replaced by fibroblasts, which persisted until the seventh passage. At this time most of the cells degenerated, and the cultures were kept for 17 days without a change of medium. A plaque of epithelial cells was then noted in one bottle, and from this plaque the strain 'ERK/1' was easily developed. The sample of 'ERK/1' cells used here was provided by Dr. J. C. N. Westwood and had been cultured in Earle's medium supplemented with 15 per cent calf serum.

The mixed agglutination reaction was developed by Coombs *et al.*[4] for the purpose, originally, of demonstrating blood group antigens on tissue cells. The reaction involves the formation of mixed clumps (which are easy to observe under a phase-contrast microscope) between tissue cells and indicator red cells if the two cell types possess a common antigen.

The adaptation of the method to the problem of recognizing the species-antigenic characteristics of cells growing in culture depends on the assumption, upheld empirically[1], that red blood cells and other tissue cells of the body, or such cells in culture, possess in common certain antigens characterizing the species. In the tests made so far, anti-red cell sera have been used and have been absorbed with tissue cells and red cells of various heterologous species to render them species-specific in their reaction[1]. In essence the reaction is performed as follows. The suspension of cultured cells under investigation is treated in separate tests with the diagnostic red cell antisera, and after being washed free of uncombined antibody is added to a suspension of homologous red cells. An affinity between the antibody-treated tissue cells and the red cells, manifested by the formation of mixed agglutination, indicates common antigenic structures and by implication the species nature of the test cell.

Subjecting 'L' and 'ERK' cells, together with a large panel of cultured cells of known origin as controls, to such an examination gave the results shown in Table 1; relevant details about each cell culture are given in a footnote to Table 1.

The specificity of the diagnostic sera used may be seen from the results of the tests on the control panel of cultured cells. There seems to be no doubt that 'L' cells are still mouse in antigenic character, since they reacted strongly with the anti-mouse serum and not at all with the sera diagnostic for the human or bovine species or that of the rabbit and pig. On the other hand, the 'ERK' cells failed to give a positive reaction with the anti-rabbit serum but reacted strongly with the anti-human serum only. The most obvious conclusion is that the 'ERK' cell is a human cell.

Other characterizing antigens may be used in such mixed agglutination tests on cultured cells besides these rather ill-defined 'species antigens'. Tests for human *iso*antigens have already been reported on HeLa cells[5], and our findings will soon be published on the use of 'heterophile' antibodies establishing the presence of antigens of the Forssman type.

We acknowledge with thanks the following grants: from the National Institutes of Health, Bethesda, to Dr. R. R. A. Coombs; from the British Empire Cancer Campaign to Dr. Mary R. Daniel; from the Wellcome Foundation to Dr. A. Kelus.

We also wish to thank Drs. T. S. L. Beswick, J. Paul, J. O. Tobin and J. C. N. Westwood, and Miss Z. Page for sending us cells used in this investigation.

Nucleic Acids as Transplantation Antigens

Much has been written about the role of nucleic acids in transplantation immunity[1-3]. From previous work it has been concluded that deoxyribonucleic acid (DNA) was not antigenic. The following results, based on chemical analysis including chromatography of sugars[4] and of purines and pyrimidines or their derivatives, suggest that ribonucleic acid (RNA) also is not a necessary part of the antigenic molecule. Antigens from mouse spleen and thymus were prepared by different procedures[5-7]. Their antigenicity was checked by techniques previously described[3].

Antigen I has been prepared by precipitation at pH 5 (Table 1). Accordingly, its RNA content was high. By incubation with trypsin, 60–80 per cent of this material was solubilized. The sediment (preparation II) kept the major part of the antigenic activity, its RNA content was considerably lowered, while its percentage in galactose + mannose was increased. Further treatment of this sediment by ribonuclease led to the removal of any detectable trace of RNA without any loss of activity (preparation III). By this treatment no change in the hexose content was found.

It must be emphasized that preparation I, not previously treated by trypsin, was resistant to ribonuclease, the RNA fraction being most probably surrounded by a protective proteic layer. The constant hexose content at about 3–4 per cent, coupled with a percentage of hexosamine to proteins at 1–2

Table 1. Composition in Percentage of some Transplantation Antigens extracted by Different Procedures

	Injected dose (mgm. of proteins)*	Proteins	DNA	RNA	Galactose + mannose

per cent, suggests that the antigenic determinant could be carried by a glycoprotein. It must be added that the presence of fucose is suspected but could not be confirmed. Rhamnose was never found. Table 1 includes the analysis of other preparations obtained by different procedures. Preparation IV[6] is, in part, based on the action of trypsin. Its composition is very near that of preparation II. Preparation V is that of Billingham, Brent and Medawar[7]; it is very rich in DNA, but its hexose content is very similar to that of previous preparations. Preparation VI[8] has been obtained by electrophoretic separation.

This work was supported in part by the Centre Anti-Cancéreux de Liége, and the Fonds National de la Recherche Scientifique.

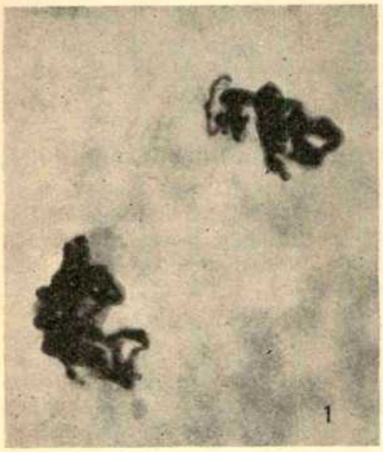
Electron Microscopic Autoradiography in a Magnetic Field

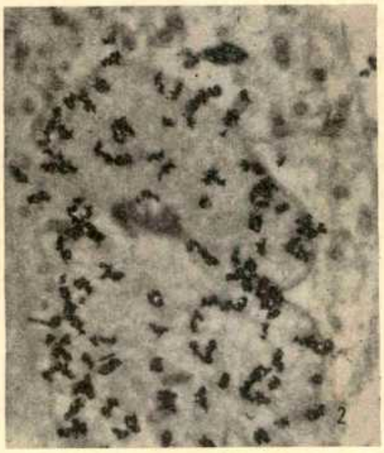
THE feasibility of electron microscopic autoradiography was suggested to us by the report of O'Brien and George[1]. We have tried a similar technique with tritiated thymidine in tissue culture and have found that recognition of reacted grains in the nuclear track emulsion may be greatly facilitated by their distinctive filamentous appearance, and that the intensity of labelling may be increased by exposing the grids in a strong magnetic field.

HeLa cells were grown in a medium containing tritiated thymidine, and standard techniques were used to prepare thin sections of the cells for electron microscopy. A small amount of Kodak nuclear track emulsion *NTB*3 was liquefied by heating in a water-bath at 45° C. and was diluted with 2 parts of water. After stirring, the diluted emulsion was allowed to stand for 20 min. at room temperature to eliminate bubbles. Sections mounted on stainless steel grids were touched to drops of the diluted emulsion, and the excess emulsion was drained away by touching the edges of the grids to filter paper. After exposure in the dark for several weeks and developing with *D*19 developer, examination in the electron microscope showed filamentous spots over the nuclei of cells (Fig. 1). Such spots were shown to be the result of radioactivity by controls in which the sections of cells were omitted and the tritiated compound was mixed with the emulsion. That the spots consisted of reacted grains in the emulsion was demonstrated when no radioactive substance was present and the grids were exposed to light.

Some reacted grains were visualized outside the nuclear membrane, and we sought to eliminate this scatter by exposure of the emulsion-covered grids to a magnetic field. The use of a magnetic field was suggested by Dr. M. Ter Pogossian, who calculated that the low-energy electrons of tritium would be affected by a flux density of 10 kilogauss and who was able to supply a magnet of this intensity. The result did not show complete elimination of scatter, and it was difficult to make any quantitative estimation of the amount of scatter. However, it was found that the reacted grains over nuclei in preparations exposed to the magnetic field were considerably more numerous than in preparations not exposed (Figs. 2 and 3).

It appears that the distinctive contour of the filamentous spots and the increased intensity of labelling brought about by the magnetic field are technical aids which may help to combine the advantages of tritium autoradiography with the resolving power of the electron microscope. The filamentous shape of the reacted grains may be used to distinguish them from other spots and from arte-





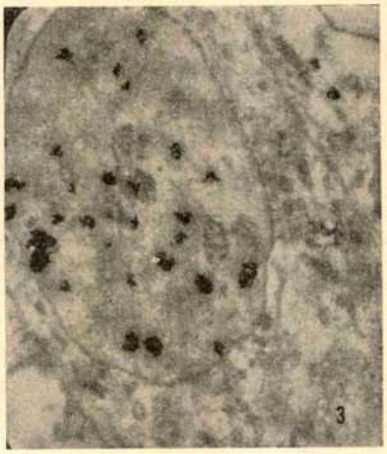


Fig. 1. Filamentous contour of reacted grains over the nucleus of a HeLa cell. The nuclear track emulsion was exposed to the section for 8 days. (× 37,500)

Fig. 2. Reacted grains over the nucleus of a cell after exposure of the emulsion to the section for 32 days in a magnetic field. (× 3,500)

Fig. 3. Control emulsion exposed to the section for 35 days without a magnetic field. (× 3,500)
Cells were grown for 2 days in the medium containing tritiated thymidine (3·3 μc. per ml. of medium, specific activity 890 mc. per m.mole)
Sections for Figs. 2 and 3 were cut from the same block and were slightly thicker than those usually used for electron microscopy

facts that may be seen in electron micrographs. The increased numbers of reacted grains after exposure of emulsion-covered grids to a magnetic field may serve to shorten the times needed for exposure and reduce the amount of radioactivity needed in thin sections to obtain satisfactory electron autoradiographs.

A more detailed account of this work will be published in *Laboratory Investigation*.

The nuclear track emulsion was generously contributed by Eastman Kodak Co., Rochester, New York.

Tritiated thymidine was obtained from New England Nuclear Corp., Boston, Mass., and Schwarz Laboratories, Inc., Mt. Vernon, New York.

These investigations were carried out under the sponsorship of the Commission on Acute Respiratory Diseases, Armed Forces Epidemiological Board, and were supported by the office of the Surgeon General, Department of the Army.

Status of the Grey Seal

THE leading article in *Nature* on "The Grey Seal and British Fisheries"[1], by relying on Rae's[2] appendix, gives a wrong impression of our knowledge of the status of the grey seal (*Halichoerus grypus*) in British waters both now and in the past. There has in fact at no time been adequate information on which to base a reliable estimate of the total population of this species. Added to this ignorance there has been, and still remains, much confusion with the common seal (*Phoca vitulina*), and the recent work of several zoologists on the biology of the grey seal has resulted in the discovery of previously unknown breeding groups which are not necessarily new colonies. An increase in knowledge of a species does not mean that there has been an increase in its numbers.

Without direct total or sample counts neither absolute nor comparative populations can be estimated except by recourse to indirect methods. The biology of the grey seal creates difficulties at all stages; for example, although the breeding season extends for about three months, the breeding cows are present only for two to three weeks, so that on no one day can they all be counted together; some have departed before others arrive. The same applies to the pups, although they are present on the average for 4–5 weeks. The number of breeding bulls is much smaller, possibly as little as one-tenth that of the cows. Does this represent all the bulls of comparable ages with the cows, or are the others alive but at sea? Again the non-breeding individuals are conspicuous by their absence[3–5]. They must be at sea or in some unknown proportion hauled out on rocks which are not used for breeding.

At other times of the year the grey seals are distributed over fairly wide areas of the seas around the coasts of Britain, as marking investigations have shown. No counts are possible under these conditions.

To make a reasonable estimate of the population, it is therefore necessary to have some idea of a life-table. Davies[6] attempted this, but, where no information was available, had to make assumptions such as the age of puberty in both cows and bulls, and the potential longevity. Annual mortality-rates were taken from Kenyon and Scheffer for the northern fur-seal. Since Hewer[7] has shown how to determine the age of a grey seal, we now know that Davies's assumptions were incorrect. The cows do not live for twelve years but for more than thirty. They do not have their first pup when two years old but when about six. Such knowledge materially affects any calculation of population numbers. The position of the bulls is still obscure; but I am informed that there may well be fewer than half as many bulls as cows in any colony, taking non-breeding and breeding individuals together. This alone would reduce the estimated population by 25 per cent.

The moral of this surely is that we should forget all previous guesses and figures since they cannot do more than lead us astray. Instead of arguing on the basis of valueless data, our efforts should be directed towards getting the data needed for reasonably sound estimates.

Meanwhile it should be remembered that even if the total number of grey seals is two or three times as great as the wildest estimate so far made, it would still be a comparatively rare seal on a world scale. The Norwegian catch of young harp and bearded seals combined (which is less than 50 per cent of the total catch) is about 300,000 per annum in recent years. Such figures could only be maintained on populations vastly in excess of that of the grey seal.

Root-knot Nematodes and Legume Nodules

PUBLISHED descriptions of the course of infestation of roots of legume species by root-knot nematodes (*Meloidogyne* spp.) are not new. As early as 1932 Godfrey and Oliveira[1] followed the process of infestation in cowpea (*Vigna sinensis*) in root observation boxes containing sterilized soil.

In the Leguminosae, where the phenomenon of symbiotic nitrogen fixation is so significant, little appears to have been done in investigating the inter-relationships between *Rhizobium* spp., root-knot nematodes and their leguminous hosts, either under experimental or natural conditions. There is a mere mention by Van Schreven[2] and Masefield[3] regarding the possible role of the nematodes in modifying nodulation and nitrogen assimilation. Christie[4] reported finding root-knot nematodes in the nodules of soybean plants that were otherwise apparently free from nematode galls.

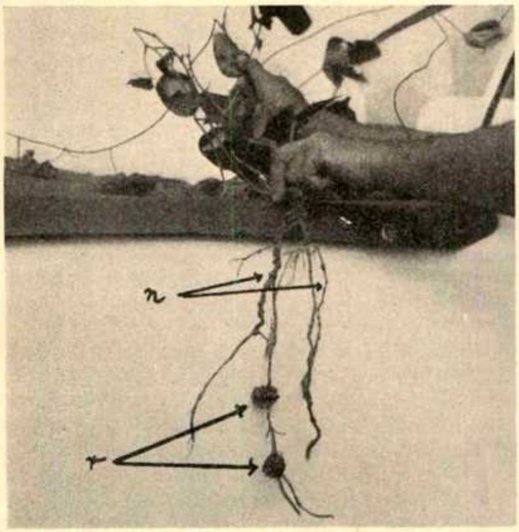

Fig. 1. Morphological difference between mature nematode-free nodules (*r*) and the gall-like structures (*n*) which may be either transformed nodules or true nematode galls, as found on velvet bean (*Stizolobium* sp.)

Recent field and laboratory observations of the root systems of the cowpea–legume group (*Vigna sinensis* var. and *Stizolobium* spp.) grown in sub-tropical and tropical locations of the sugar cane belt in Australia show that: (1) the infestation of nodules (and other root sites) of the above legumes by the root-knot nematode, *Meloidogyne javanica* (Treub) Chitwood, is a common occurrence in these localities; (2) on certain plants the nodules only may be attacked; (3) throughout one growth-cycle a large percentage of nodules may become infested; solitary nodules in lower root zones will often escape infestation; (4) nodules reach various sizes before initial infestation though smaller (younger ?) nodules appear more susceptible.

The finding of nodules in all intermediate stages from those exhibiting larval penetration only (together with a preponderance of *Rhizobium*-occupied tissue) to those in which multiple or secondary infestation (but no bacteria) predominates suggests that the production of nodule or gall depends on the subsequent development of the early nodule after attack by the eelworm (Fig. 1). It is not yet known whether nodules can resist or recover from nematode infestation, and answers to these questions are being sought from present work under controlled conditions.

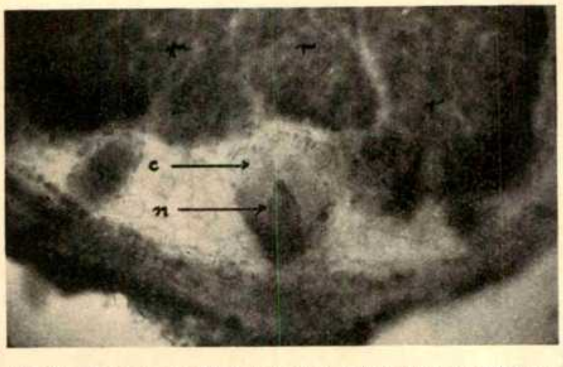

Fig. 2. Transverse section through a nodule from velvet bean showing (*r*) inner tissue containing *Rhizobium*-filled cells, (*n*) sessile female *Meloidogyne* developing in the outer cortex, behind which the outlines of giant multinucleate cells may be seen (*c*). (× *c*. 56)

One interesting feature of the secondary infestation of the nodule by the nematode is that giant cells develop on which the swollen female nematode feeds, as in the case when plant roots are carrying true nematode galls (Fig. 2). This raises the intriguing speculation as to whether a third member (the nematode) may be added to the physiologically specialized relationship which now exists between legume host and *Rhizobium* spp.

In so far as the cowpea–legume group is concerned, the nematode–nodule association is sufficiently widespread to encourage inquiry into its effects on: (*a*) the establishment and growth of the cowpea species used for green manuring throughout the Australian sugar cane belt; (*b*) the symbiotic nitrogen assimilation of such crops. These matters will continue to be investigated at the Macknade Experiment Station in North Queensland.

I thank Dr. J. B. Goodey, Rothamsted Experimental Station, for identifying the root-knot nematode.

ENTOMOLOGY

Toxic Hazard from formulating the Insecticide Dimethoate in Methyl 'Cellosolve'

DIMETHOATE (O,O - dimethyl S - (N - methylcarbamoylmethyl) phosphorodithioate) is an effective systemic insecticide for use on plants[1-3], has shown promise as a chemotherapeutic agent for control of cattle grubs[4,5] and certain other insect pests of farm animals, and has high contact toxicity to house-flies and many other insects. The pure material, with a rat oral *LD*50 of about 600 mgm./kgm., is the least toxic to mammals of the systemic insecticides at present available for use in controlling plant pests. Commercial dimethoate is 2–4 times more toxic to rats than the pure compound, and repeated recrystallization or chromatography is required to achieve the reduced mammalian toxicity of the pure material. Several investigations have been reported on the chemical[6] and biological[7-9] degradation of dimethoate.

During the purification of commercial dimethoate, a fraction was separated which potentiated the rat oral toxicity of pure dimethoate. Addition of 2–10 per cent of this fraction to pure dimethoate potentiated its toxicity (rat oral *LD*50) by 3–4 times, a finding which at least partially explains the difference in toxicity between the pure and commercial material. This fraction also potentiated the toxicity of malathion and O,O-dimethyl S-carbamoylmethyl phosphorodithioate to the rat. The potentiator appears to be effective only with certain species, since the commercial material was more toxic than the pure compound to rats, guinea pigs, rabbits and hens, but not to mice, pheasants, locusts, aphids and flies. With rats the potentiator was active by the oral and intra-peritoneal routes but not following dermal administration. On demethylation of dimethoate by reaction with salts of O,O-dimethyl phosphorodithioic acid, O,O,S-trimethyl phosphorodithioate and a potentiating material were formed. The potentiator, also formed by the reaction of dimethoate with lithium chloride, may be a salt of O-methyl S-(N-methylcarbamoylmethyl) phosphorothioic acid or a closely related compound. On analogy with the potentiation of pure dimethoate by O-ethyl O-*p*-nitrophenyl phenylphosphonothionate, tri-*o*-cresyl phosphate and tri-*o*-cresyl phosphorothionate[10], it would appear that the potentiating impurity in commercial dimethoate might act by reducing the efficiency of the dimethoate detoxification mechanism acting through hydrolysis of the carboxyamide grouping.

Methyl and ethyl 'Cellosolve' (2-methoxy- and 2-ethoxyethanol) have excellent solvent characteristics for the formulation of organophosphorus insecticides, particularly where a high degree of systemic activity is desired after application to foliage. As a result of routine toxicity checks on the properties of technical dimethoate formulated in methyl 'Cellosolve', an unexpected toxic hazard was observed. The rat oral *LD*50 decreased on storage from an initial 150–250 mgm./kgm. to 30–40 mgm./kgm. after seven months storage in England. After nine months storage under tropical conditions the *LD*50 was less than 15 mgm./kgm., and after storage at 100° C. for 63 hr. in the laboratory the *LD*50 was 8 mgm./kgm. The mammalian toxicity increased several-fold before any change in insecticidal activity was evident. Further development of this unstable formulation was immediately stopped.

Chromatography by described procedures[7,8] of the decomposed dimethoate in methyl 'Cellosolve' yielded fourteen phosphorus-containing products. The degradation involved hydrolysis at the amide and all the ester groupings, a marked loss of thiono sulphur, and replacement of both the O-methyl and N-methylamino groupings by 2-methoxyethanol. No evidence was obtained for the formation of pyrophosphates or thionopyrophosphates. The most toxic fraction was purified and identified as an O,O-dialkyl S-(N-methylcarbamoylmethyl) phosphorothiolate with probably one, but possibly both, methyl groups of dimethoate replaced by 2-methoxyethyl groupings. This compound was less toxic to flies than dimethoate, but had a rat oral *LD*50 of about 1 mgm./kgm. and a mouse intra-peritoneal *LD*50 of about 0·5 mgm./kgm. The increase in toxicity to mammals of the decomposed dimethoate formulation was greater than that attributable solely to this single toxic product. Since no other single component was toxic enough to account for the discrepancy, it appears that a potentiation of toxicity also occurred among the materials in the dimethoate - methyl 'Cellosolve' formulation.

The relationship of stability to toxicity of dimethoate formulated in a number of solvents was investigated. Little if any hydrolysis or change in mammalian toxicity occurred in non-hydroxylic solvents. Polyhydroxylic solvents resulted in stability during short storage without the formation of highly toxic degradation products. Of several monohydroxylic solvents, only methyl and ethyl 'Cellosolves' resulted in formulations highly toxic to mammals on short-term storage at 70° C. From this work a commercial formulation was developed which showed no significant change of toxicity after 162 days storage at 40° C.

The potential hazard which could have arisen is not unique for dimethoate, since O,O-dimethyl S-(N,N-dimethylcarbamoylmethyl) phosphorodithioate, O,O-dimethyl S-(1,2-dicarbethoxyethyl) phosphorodithioate (malathion), O-methyl O-(2,4,5-trichlorophenyl) phosphoramidothionate (Dow *ET*-15) and O,O-dimethyl O-(2,4,5-trichlorophenyl) phosphorothionate (Dow *ET*-57) were also found to show a several-fold increase in mammalian toxicity after reaction with methyl 'Cellosolve' at 70° C. for eight days.

When 'Cellosolves' are to be used in formulating phosphorothionate insecticides, the possible ester and amide exchange reactions to yield products of increased mammalian toxicity should be carefully investigated. A more complete account of these investigations will appear elsewhere.

Publication of this communication is approved by the Director of the Wisconsin Agricultural Experiment Station, and by the Directors of Fisons Pest Control, Ltd. The investigation was supported in part by a Haight Travel Fellowship from the Graduate School of the University of Wisconsin to one of us (J. E. C.), and by grants from the U.S. Public Health Service, National Institutes of Health, and from the U.S. Atomic Energy Commission (Contract No. *AT*(11–1)–64, project No. 14). We thank Dr. E. F. Edson, Dr. G. S. Hartley, Mr. A. J. Lambie and Mr. P. Carter of Fisons Pest Control, Ltd., and Mrs. Lydia McBride of the University of Wisconsin, for their encouragement and assistance.

Lysine as a Mosquito Attractant

PREVIOUS work has indicated that attractive factors other than carbon dioxide are present in the vapour from mammalian blood[1] and body exudations[2]. A distillate obtained from mammalian blood proved highly attractive to *Culex pipiens*[3]. It has been recently reported that a mixture of nine biological acids and bases was attractive to *C. pipiens* and

Anopheles maculipennis at concentrations down to 0·05 per cent, although none of the compounds was attractive when tested individually[4].

Our experiments on *Aedes aegypti* were guided by an old report[5] that peptone and certain amino-acids had shown attractiveness for *A. sollicitans*, and by the fact that protein hydrolysates are employed successfully as baits for fruit flies. Control and experimental solutions were exposed on filter-paper in warm Petri dishes[1] in a cage containing mosquitoes maintained only on sugar-water; the number of approaches to the experimental solution, as compared to that to the control, was expressed as the attractiveness ratio. Of 16 different protein hydrolysates commercially available and tested in 10 per cent solution, 11 proved to be attractive. Of these, 8 were more attractive than ox blood plasma; on distilling them to dryness at 7 mm. mercury pressure and 37° C., the distillates of five of them proved significantly attractive.

Individual amino-acids were then tested, dissolved in distilled water in the relative amounts in which they occur in 10 per cent lactalbumin hydrolysate. Of the 17 tested, the only amino-acids to be significantly attractive were (with their attractiveness ratios): L-arginine 1·24, L-alanine 1·32, and L-lysine 3·84. A mixture of all the amino-acids except lysine showed an attractiveness ratio of 1·14; addition of lysine raised the attractiveness ratio to 2·80. At the buffered *p*H of 7·4, lysine showed an attractiveness ratio of 3·13, and raised the attractiveness ratio of the amino-acid mixture from 1·28 to 6·13.

L-Lysine hydrochloride was not attractive in acid solution, but became highly attractive in alkali (attractiveness ratio 2·59 at *p*H 7·4); L-lysine free base was attractive also in acid solution (attractiveness ratio 5·62 at *p*H 4·4). The hydrochloride of the unnatural enantiomorph D-lysine showed an attractiveness of 1·20 at *p*H 6·5 and of 3·70 at *p*H 11·6. The potency of L-lysine at *p*H 10 was such that in 0·001 per cent and 0·0001 per cent (1 p.p.m.) solutions its attractiveness ratios were respectively 5·95 and 2·86. When a 0·7 per cent solution of L-lysine was distilled at 7 mm. mercury pressure and 37° C., the distillate showed an attractiveness ratio of 7·73 and gave a positive ninhydrin test.

When a mixture of 0·88 per cent L-lysine and 0·24 per cent L-alanine was chromatographed through a 50 × 1·2 cm. column of 'Dowex 50*W*-*X*4' resin[6] and the successive eluate fractions tested, the attractiveness of alanine appeared at 40–50 ml. and that of lysine at 75–88 ml. after the addition of the sample to the column. When deproteinized lactalbumin hydrolysate (10 and 0·1 per cent solutions assayed) was similarly fractionated, the greatest attraction was at 66–90 ml., with a minor peak at 53 ml. The fraction at 87 ml. was tested by paper chromatography and found to contain L-lysine. When deproteinized ox blood plasma was chromatographed, the main peak of attractiveness was around 90 ml., with a smaller peak at 30–50 ml.; the amino-acid present in the 93- and 88-ml. fractions was identified as L-lysine. When deproteinized human blood plasma was fractionated, the main peaks were at 40–50 ml. and around 80 ml.; the fractions at 44 and 81 ml. were found to contain L-alanine and L-lysine respectively. In all the fractionations, a minor peak was found at about 120 ml., possibly due to L-arginine.

The results thus indicate that the most attractive principle in the protein hydrolysate and blood plasmas tested was L-lysine. Of possible contaminants, ornithine and asparagine showed no attractiveness, whereas ammonia, putrescine and cadaverine were strongly repellent at high concentrations and never became attractive on progressive dilution. L-Lysine proved attractive not only to the Orlando strain of *Aedes aegypti*, but also to strains from Penang, Key West and Trinidad. It was also attractive to field-caught *Aedes stimulans*, and to *Culex pipiens* at evening. A solution of L-lysine exposed in the cage stimulates the resting mosquitoes to take flight, and they react to it as to a guinea pig or human hand. The concentration of L-lysine in human blood[7] and sweat[8] is about 27 μgm. per ml. Since it may be distilled from aqueous solution and is attractive at 1 p.p.m., L-lysine could thus be the main attractive factor of mammalian blood and body emanations.

Full details of the work will be published elsewhere. We are indebted to the Defence Research Board of Canada for financial support of these investigations.

A Method of dissolving the Protective Spittle Masses of Frog Hopper Nymphs

DURING the course of biochemical investigations into the nature and composition of the spittle masses produced by cercopid nymphs (*Philaenus spumarius* L. and *Neophilaenus* sp.) it was observed that these masses decomposed within a few minutes of being placed in a 2/3 *N* solution of sulphuric acid.

Since Cercopidae are of considerable economic inportance, especially *Aeneolamia varia saccharina* in the cane sugar industry, and are protected from the action of insecticides by the spittle which they produce, it was realized that the above observation might be utilized in the measures taken for their control.

It was shown in the laboratory that the rate of solution of spittle masses (Fig. 1) was dependent on the normality but largely independent of the nature of the acid, hydrochloric and nitric being as effective as sulphuric acid. Since the rate of solution is not only dependent on the normality of the acid, but also on size of spittle mass and amount of agitation, the values given in Fig. 1 therefore relate only to spittle masses of the size produced by late fourth and early fifth instar nymphs, and subjected to gentle agitation. Field trials were then carried out using sulphuric acid at various concentrations. This acid was chosen because of its low vapour pressure. Dieldrin (0·06 per cent), added as Shell 'Dieldrex', was added to each solution to kill exposed nymphs and thus prevent the production of new spittle masses. The results are given in Table 1, which also shows the effect of weather on both the rate and total destruction of spittle masses.

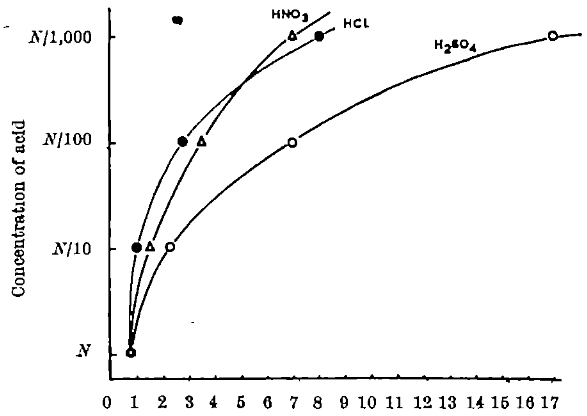

Fig 1. Rate of solution of spittle by acids

The phytotoxic effects of sulphuric acid on maize and oats, when sprayed as above at concentrations up to 2 *N*, were found to be negligible. Scorching of the leaves was produced by *N* and 2 *N* acid sprayed on at the rate of 100 gal./acre, but not by solutions of *N*/5 and *N*/10 acid. In neither case were subsequent growth and flowering affected by this treatment.

Similar results were found for grasses (species as in Table 1) although when using *N* acid the degree of scorching was distinctly greater. The use of *N* acid alone in this test resulted in a 95 per cent destruction of spittle masses within 48 hr.

Table 1. PERCENTAGE DESTRUCTION OF SPITTLE MASSES BY SULPHURIC ACID

Plots of grasses, each containing *Arrhenatherum elatius*, *Deschampsia caespitosa*, *Agrostis tenuis* and *Holcus lanatus*, were sprayed with solutions of sulphuric acid or water each containing 0 06 per cent dieldrin.

Test A. Carried out during a period of showery weather (total for the 3 days of the test. rainfall, 0 29 in.; sunshine, 15 5 hr.) on 4½ sq. yd. plots sprayed at the rate of 110 gall/acre.

Time (days)	Percentage destruction of spittle masses 1	2	3
N/5+0 06 per cent dieldrin	50 (41)	65 (59)	65 (62)
N/10+0 06 per cent dieldrin	38 (27)	59 (52)	62 (51)
Control (distilled water + 0 06 per cent dieldrin)	15	15	8

Corrected percentage destruction in parenthesis.

Test B. Carried out during a period of dry sunny weather (total for the 8 days of the test rainfall, 0 01 in.; sunshine, 17 6 hr.) on 5 sq. yd plots sprayed at the rate of 100 gall /acre:

Time (days)	Percentage destruction of spittle masses 1	2	3
N/5+0 06 per cent dieldrin	21 (28)	58 (62)	81 (81)
N/10+0 06 per cent dieldrin	38 (43)	51 (55)	85 (85)
N/50+0 06 per cent dieldrin	14 (21)	22 (28)	51 (51)
Distilled water+0·06 per cent dieldrin	0 (8)	3 (11)	30 (30)
Control untreated	−9	−9	0

Corrected percentage destruction in parenthesis.

These preliminary results therefore suggest that if sulphuric acid is added to solutions of acid-stable insecticides to give a final concentration of *N*/5, the nymphal mortality of Cercopids will be greatly increased. Using higher concentrations on crops not damaged by *N* and 2 *N* acid, an even greater mortality of nymphs can be achieved.

BACTERIOLOGY

Microbial Production of Carbon Monoxide from Flavonoids

Aspergillus flavus degrades rutin to protocatechuic acid, phloroglucinol carboxylic acid, rutinose and carbon monoxide, the last-named being derived from carbon 3 of the flavonoid molecule[1,2]. The extent of distribution of this degradative pathway in micro-organisms and the structural requirements for the production of carbon monoxide were determined by comparing the amount of carbon monoxide produced after the growth of micro-organisms on various flavonoid compounds. The cultures studied were grown in sealed flasks of known volume[3]. A medium containing *N*—*Z* amine[1] was used when the substrates tested could be analysed by the aluminium chloride reaction. A synthetic medium[4] was employed with substrates that were difficult to determine directly and the amount of oxygen consumed was therefore used as the criterion of substrate utilization. Carbon monoxide and oxygen were determined by gas phase chromatography using a molecular sieve column.

The production of carbon monoxide from flavonoids is a common reaction in moulds but is absent in the bacteria tested (Table 1). As the recoveries of carbon monoxide are in general less than theoretical for the amount of substrate metabolized, there must be more than one pathway available to moulds for growth on flavonoid compounds.

A hydroxyl group in the 3-position is required for carbon 3 to be released as carbon monoxide (Table 2). Production of carbon monoxide is unaffected by the degree of saturation existing between carbons 2 and 3, or by the presence of a glycosidic bond in the 3-position (Tables 1 and 2).

Flavanol	Catechin	3,5,7.3′,4′-pentahydroxyflavan	12·6	6·9

* *Fusarium* sp.

A. flavus cannot readily utilize quercitrin (quercetin-3-rhamnoside), but does utilize the aglycone; quercetin was obtained from quercitrin by acid hydrolysis. This implies that the production of the glycosidase which splits the rhamnosidic bond is the factor limiting growth on this substrate. It would also appear that the production of this enzyme limits the growth of the *Alternaria* sp. studied on quercitrin.

The effect of a 3-hydroxyl group on the point of cleavage of flavonoid compounds has been noted by Booth *et al.*[5]. These authors found that mammalian systems degraded flavonoid compounds with a 3-hydroxyl group to yield a phenolic acid with a 2-carbon side-chain, while those without this group yielded a phenolic acid with a 3-carbon side-chain.

The position of the substituent groups (that is, hydroxyls and methoxy groups) does affect the utilization of flavonoid compounds by micro-organisms (Table 3). For example, these cultures did not readily utilize morin as a carbon source but did use quercetin and kaempferol. It can be shown by use of molecular models that this is a result of the steric hindrance of the 3-position by the presence of a 2′-hydroxyl group. This steric hindrance implies a change in the electron distribution pattern around carbons 2 and 3 and/or hydrogen bonding between the 2′- and the 3-hydroxyl groups. The 4-position is implicated as being an active centre in the enzymatic attack of flavonoids as catechin was not readily utilized as a carbon source. Similarly, the 5-position is implicated by the low utilization of fisetin, robinetin and azaleatin. As apigenin, naringenin and taxifolin were readily utilized as carbon sources, neither a double bond between carbons 2 and 3 nor a hydroxyl group in the 3-position is required for ready utilization of the flavonoid molecule. The presence of methoxy groups on the flavonoid molecule interferes with the utilization of these compounds as carbon sources by the micro-organisms studied. However, the presence of a single methoxy group in the 7-position is without effect.

Hattori and Noguchi[6] reported the isolation of the depside of phloroglucinol carboxylic acid and protocatechuic acid after the growth of *Pullularia fermentans* var. *candida* on rutin. As the pathway outlined by our work[1,2] results in a similar product, it is quite likely that the carbon monoxide-producing pathway was used by *P. fermentans* during growth on rutin.

Micro-organisms[7], plants[7] and animals[8] have been reported to produce carbon monoxide. This communication reveals that flavonoid compounds are a potential source for carbon monoxide production by moulds. These facts, together with reports that micro-organisms are known which oxidize carbon monoxide[9], suggest that carbon monoxide is an important, active, 1-carbon metabolite in the carbon cycle.

Examination of *Leptospira pomona* by Gel Diffusion

IN recent years, diffusible antigens of many bacteria and viruses have been demonstrated by the double-diffusion precipitation reaction in agar. Except for the work of Rothstein and Hiatt[1], who used the Oudin[2] technique in the study of chemically prepared fractions, we do not know of any investigation involving application of these methods in the study of *Leptospira*. This communication describes the results of an antigenic analysis of the four sub-serotypes of *Leptospira pomona*, attempted by diffusion of antigens and antibodies in agar.

Employing Mansi's[3] modification of Ouchterlony's[4] technique and hyperimmune sera prepared in rabbits, one common major line of precipitation was noted between antigen and antibody reservoirs when four antigenic sub-types were reciprocally examined against each other. However, differences in the line patterns were detected in the homologous systems; strains *pomona*, *C–B* and *C*-164 giving two reaction zones and strains *S*-91 and *G*-6 (Pande and Sekariah, 1960 [5]) producing only one line. These findings were confirmed with absorbed sera.

When fractions 1, 2 3 and 4 prepared from these sub-types, on the lines of Schneider[6], were tested against the homologous whole-cell antisera, a single line was detected with fractions 1 and 2 but no line with fractions 3 and 4, indicating that perhaps the latter antigens were located deep in the cell. Further tests showed that fractions 1, 3 and 4 were common to all sub-types within this serotype, while fraction 2 appeared to determine differences in serological reactivity.

When immune rabbit serum was examined against infected tissues, such as saline extracts of kidney lesions, a strong reaction was seen, whereas no reaction occurred between normal rabbit serum and infected tissues or suspensions and extracts of *Leptospira*. It has been found that 5 per cent formalin and 50 per cent glycerine do not destroy the antigen, and the test can be carried out satisfactorily on infected tissues preserved with these reagents.

It is intended to use this method in investigating field specimens obtained from suspected cases of leptospirosis in domesticated animals in India.

This test has also been successfully applied to detect antibodies in suspected sera when positive specimens were found to produce a single line of reaction within 2–3 hr. in the slide modification of the gel-diffusion test[7]. Precipitins could be detected by a comparable titre in the plate test. Further investigation is in progress to evaluate the diagnostic sensitivity and reliability of this method, on a comparative basis, the results of which will be reported in detail elsewhere.

We are indebted to Col. M. B. Starnes and Mr. A. D. Alexander, Division of Veterinary Medicine, Walter Reed Army Institute of Research, Washington 12, D.C., who kindly supplied the four sub-types of *L. pomona* and the homologous antisera.

Localization of a Protease in the Cell of *Escherichia coli*

The cells of *Escherichia coli* contain a protease during their whole growth-cycle. This protease is inactive in living cells and its presence can be demonstrated only after disruption of the cell structure[1]. In connexion with the study of the function of this protease in the metabolism of intracellular proteins its localization in the cell was also investigated.

Spheroplasts were prepared from a 4-hr. culture of *E. coli B* by Lederberg's method[2] using penicillin. 20–30 per cent of the protease activity was transferred to the medium during the preparation of the spheroplasts. Because a part of the spheroplasts was disintegrated and their cellular proteins made soluble at the same time, it can be presumed that a greater part of the enzyme thus liberated is of intracellular origin. The spheroplasts were disrupted by osmotic shock in 0·01 *M tris* at *p*H 8·0 with 5×10^{-3} *M* magnesium chloride. The material was then centrifuged in the cold at 10,000*g* for 10 min. in an MSE centrifuge, the sediment washed with the buffer and again spun down. The combined supernatants were centrifuged for 1 hr. in a cooled Phywe ultracentrifuge at 105,000*g*, the pellet resuspended in the buffer and again spun down. The sediment at 105,000*g* exhibited a characteristic absorption at 257 mμ. The protease activity was determined with casein labelled with iodine-131 substrate[3] and referred to mgm. of protein, on one hand, and expressed as per cent of the whole amount of the enzyme, on the other. A loss of about 20 per cent of the enzymatic activity occurred during these operations.

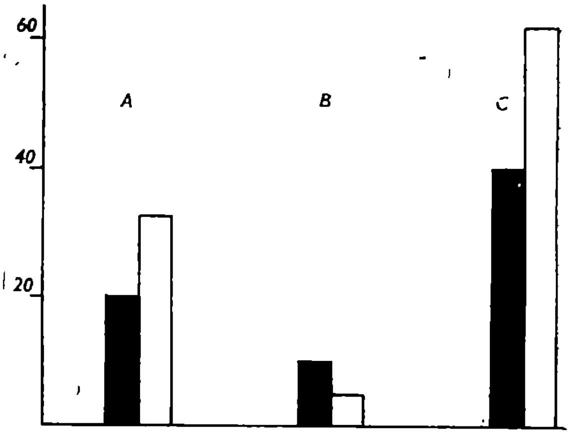

Fig. 1. Localization of a protease in cellular fractions of *E. coli*. *A*, Cytoplasmic membrane fraction; *B*, ribosome fraction; *C*, cytoplasm. Black columns, activity in μgm. of casein hydrolysed by 1 mgm. of protein during 1 hr. at 37° C.; white columns, percentage of total amount of protease

It was found that the enzyme is present mainly in the cytoplasm and in the fraction which sediments at 10,000*g* and contains the cytoplasmic membrane and remains of the cell wall. Only a very small part of the whole amount of enzyme was present in the fraction of ribosomes which sedimented at 105,000*g* (Fig. 1). Enzymatic activity in the ribosome fraction probably is not due only to contamination, because the protease activity, related to mgm. of proteins, amounts in this fraction to about one-half of that of cytoplasmic membrane and cannot be completely removed by washing. A certain amount of active protease present in the ribosome fraction in the *E. coli* cell is analogous to the localization of the peptidase[5]. The ribosomes of *E. coli* also contain a ribonuclease[6] which is present in an inactive form and is activated after the disruption of ribosomes by ethylenediamine tetraacetic acid (EDTA) or urea. An attempt was made to verify the possibility that the inactive form of protease was present, and the influence of these substances on the activity of the protease in the fraction which sediments at 105,000*g* was therefore studied. The enzymatic activity was found to be reduced by EDTA at a concentration of 1×10^{-2} *M* by 70–80 per cent and the enzyme was completely inactivated by 4 *M* urea. The decrease in activity caused by EDTA was about the same in the fraction of ribosomes and in the cytoplasm and thus the presence of inactive protease in the ribosomes appears unlikely. The results obtained from fractions isolated from disrupted spheroplasts were checked by using material homogenized in the bacterial press[7]. It was found that in this case the enzyme was also distributed quite evenly between the fractions sedimenting at 10,000*g* and the cytoplasm. Here, too, only a small part of the whole amount of protease was found in the fraction of ribosomes.

VIROLOGY

Presence in Horse Serum of Two Inhibitors of Avid *A*2 Influenza Virus Strains

Recently it has been shown[1-3] that normal sera from some animals contain substances which inhibit specifically the avid[4] *A*2 influenza virus strains. Attention has been paid to these substances, as they exhibit not only hæmagglutination-inhibiting activity, as the α-inhibitors, but also virus-neutralizing activity.

In our laboratory two inhibitors of avid *A*2 influenza virus strains, showing different mobilities in the electric field and differing also in other properties, were isolated from normal horse serum.

The faster-moving inhibitor, designated as glycoprotein inhibitor, was isolated from the lyophilized sulphosalicylic acid filtrate of the serum[5] by extraction with an equal volume of 90 per cent phenol at 65° C. for 30 min.[6]. The water layer was freed of phenol by dialysis and then lyophilized. The substance obtained showed a single boundary on electrophoresis and sedimentation in the analytical centrifuge. It was of a glycoprotein nature, containing 18–20 per cent hexoses, 14·8–16 per cent sialic acid, 11·5–12·5 per cent hexosamines and 38–40 per cent polypeptides. 1 mgm. of this glycoprotein contained 6,400–12,000 hæmagglutination-inhibiting units against 4 hæmagglutination units of the avid *A*2 (Singapore) 57 influenza virus strain (eighth egg passage) and neutralized 100–1,000 $TCID_{50}$ of this virus up to 1 : 1,024 dilution. The action of a 0·1 per cent solution of crystalline trypsin at *p*H 8·0 and 37° C. for three days lowered the inhibitory activity of the inhibitor 50–100 times. 400–800 units of receptor destroying enzyme have split 43–50 per cent of the total sialic acid from 2 mgm. of the glycoprotein, without affecting the activity of the inhibitor.

The slowly moving inhibitor, designated as γ-globulin inhibitor, was isolated from horse serum by precipitation with a 0 01 per cent solution of 'Neokal *B*' (commercial preparation of a butylnaphthalene-sulphonate) in phosphate buffer *p*H 6 4 and 0·02 ionic strength. The serum was mixed at 0° C. with the 'Neokal' solution in the ratio 1 : 30, the precipitate separated by centrifugation, redissolved in saline and dialysed against distilled water. During the dialysis the euglobulins, containing the bulk of the biological activity, were precipitated. They were used in this work without further purification. The electrophoretic and sedimentation patterns of this substance showed the presence of two components. 1 mgm. of the γ-globulin inhibitor contained 400–800 hæmagglutination-inhibiting and 512–1,024 virus-neutralizing units.

Both inhibitors isolated from horse serum were specific, in that they reacted only with the avid *A*2 influenza virus strains. Potassium periodate in 0·001–0·005 *M* concentrations completely inactivated the inhibitors at room temperature in 15 min.

The two inhibitors were separated from their mixture by paper electrophoresis using diethyl-barbiturate buffer *p*H 8·6 as electrolyte and recovered by elution of 1-cm. strips. The maxima of the hæmagglutination-inhibiting activity coincided with those of proteins, this being in agreement with the results obtained by other authors[7] with unfractionated horse serum.

Table 1. Hæmagglutination-Inhibiting Activity of the Glycoprotein and γ-Globulin Inhibitors after Different Treatments

Treatment, fraction, original concentration	Hæmagglutination-inhibiting units per ml.	
	Glycoprotein inhibitor	γ-Globulin inhibitor
'Neokal', supernatant, 2 mgm./ml.	32,768	0
'Neokal', precipitate, 35 mgm./ml.	no precipitate	16,384
Sulphosalicylic acid, filtrate, 20 mgm./ml.	131,072	0
Sulphosalicylic acid, precipitate, 35 mgm /ml.	no precipitate	2,048
Heating at 100° C. for 30 min., supernatant, 5 mgm./ml.	131,072	64
Heating at 100° C. for 30 min., precipitate, 5 mgm./ml.	no precipitate	0

Table 2 Some Properties of the Horse Serum Inhibitors against Avid *A*2 Influenza Virus Strains

Properties	Glycoprotein inhibitor	γ-Globulin inhibitor
Sedimentation constant (S_{20})	3 66 *S*	14 7 *S** and ~ 5·9 *S*
Mobility in the electric field at *p*H 8·6	with α-globulins	between β- and γ-globulins
Solubility in distilled water	soluble	insoluble
Hæmagglutination-inhibiting units per mgm.	13,107	409–1,638
Virus-neutralizing units per mgm.	1,024	512–1,024

* Main component

The differences in some properties of the inhibitors (solubility, sedimentation-rate, mobility in the electric field, hæmagglutination-inhibiting and virus-neutralizing activities) as well as the changes in their hæmagglutination-inhibiting activity after heating at 100° C. and treatment with 'Neokal', sulpho-salicylic acid and phenol are presented in Tables 1 and 2.

On the basis of the results so far obtained we may conclude that normal horse serum contains at least two specific inhibitors of avid *A*2 influenza virus strains. The inhibitor moving faster in the electric field is an acid serum glycoprotein, and the slow one—so far not characterized in detail—is of a γ-globulin nature.

SOIL SCIENCE

Soluble Aluminium in Plants and Soils

Highly soluble aluminium concentrations in extracts of certain acid soils were first noted at least as early as 1904 [1]. It has been commonly explained as being due to aluminium ions held by chemical and physical means within the mineral part of the soil[2]. This mechanism usually requires a close correlation between soil pH and the concentration of soluble aluminium[3]; but, such correlation does not always occur.

The idea of accumulation of aluminium by plants is very old[4]. 'Aluminium accumulators', defined as plants which habitually accumulate appreciable quantities of aluminium in their tissues, have been regarded as a source of aluminium in the soil[2]. An exhaustive study of the aluminium content of leaves of plants in herbaria and from the British Colonies was made by Chernery[5,6]. Without considering the aluminium content of soils, he assumed that those specimens with more than 1,000 p.p.m. soluble aluminium according to the aluminon test would be accumulating species and those with less present in the leaves would be normal species. Various authors[7,8] have since used these data to explain soluble aluminium accumulation in soils, while Lovering[9] has suggested that it is a possible origin of bauxites and laterites.

Certain species are also thought to be dependent on a sufficiently high content of soluble aluminium in the soil for normal healthy growth[2]. Simonson[10] has suggested that there should therefore be indicator species to help in soil survey work. As Hutchinson[2] points out, there are undoubtedly many chemical forms in which soluble aluminium can occur in soils, and it can probably exist in appreciable quantities at all levels of pH.

During a detailed soil survey of an area of 30,000 acres on the coastal plain of British Guiana, a special study was made of the occurrence of species in the natural vegetation cover in relation to the distribution of soluble aluminium in the soil. The soluble aluminium could not have come in from outside, while drainage conditions and past history precluded the objections put forward by Chernery[11] in reply to Polynov[7]. Both high and low concentrations occurred at field pH values in the range < 4–8·5. No correlation with plant species was obtained, but there was a marked direct relationship between the return and accumulation of organic matter in the soil and the amount of soluble aluminium present in the same layer. Where secondary bush was allowed to grow, higher figures were obtained for both the organic matter content and the soluble aluminium in adjoining areas which had had a similar land-use history up to 1936.

The outstanding thing about the climax flora and distribution of soluble aluminium content was the wide range of tolerance of all species (Table 1). In an adjoining area[12], concentrations of soluble aluminium up to 13,986 p.p m. alumina have been reported in the surface A_1 horizon with a similar but rather stunted vegetation cover. Clearly these species grow equally well under conditions of both high- and low-soluble aluminium content in the soil. This might be expected since the flora has entered the area with high concentrations from the adjacent interior[13], where the soils have very low values for soluble aluminium.

The only explanation of these results would appear to be that the plants are absorbing aluminium from the soil, accumulating it and returning it with the soil organic matter. Owing to the action of earthworms (which live at pH values at least as low as 3·5), and other microfauna which mix up the organic matter with the upper mineral horizons at the drier sites, and the generally swampy conditions, there is an enrichment of the surface layers of the soil in organic matter and in soluble aluminium (probably as a chelate). In the absence of signs of any other processes, levels of soluble aluminium as high as 13,986 p.p.m. aluminium can only be obtained in this way.

Table 1. TOLERANCES OF SOLUBLE ALUMINIUM CONCENTRATIONS IN THE ROOT ZONE OF THE MAIN SPECIES IN THE CLIMAX FLORAS OF THE COASTLANDS OF BRITISH GUIANA

Climax (ref. 16)	Species	Family	Soluble aluminium content of the root zone (Al^{3+} p.p.m.)
Palm marsh forest	*Adiantium intermedium*	Polypodiaceae	120–570
	Cecropia angulata	Urticaceae	6–713
	Desmoncus sp.	Palmae	41–645
	Euterpe edulis	Palmae	63–2,962
	Miconia racemosa	Melastomaceae	63–645
	Montrichardia arborescens	Araceae	16–2,962
	Pentaclethra macroloba	Leguminosae	63–962
Swamp forest	*Mauritia flexuosa*	Palmae	120–2,962
	Mikania micrantha var. *congesta*	Compositae	120–760
	Pterocarpus officinalis	Leguminosae	179–1,200
	Tabebuia insignis var. *monophylla*	Bignoniaceae	160–2,962
Herbaceous swamp	*Blechnum serrulatum*	Polypodiaceae	91–2,962
	Cyperus luzulae	Cyperaceae	37–1,200
	Eleocharos interstincta	Cyperaceae	14–2,926
	Jussieua nervosa	Oenotheraceae	312–2,926
	Leersia hexandra	Gramineae	16–2,962

The process could operate faster if a 'compound interest' effect operated. The whole idea of using artificial fertilizers is based on a similar principle. Even in leached tropical soils, accumulations from plant tissues cause the surface layer generally to be richer in plant nutrients than the deeper horizons. It would therefore seem not unreasonable to expect that the accumulation of soluble aluminium in leaves of plants would increase as the available supply of soluble aluminium in the soil is increased. There is some evidence for this. Church[14] and Stoklasa[15] found widely different values for the aluminium content of *Aspidium filix-mas*. Chernery[5] also reported two greatly differing amounts in the tissues of *Eleocharis equisitina* from different environments. Further work is now being carried out to verify those relationships.

Lewis : "The Role of Bradykinin in the Control of Local Blood Flow".* (Eleventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institution of Electrical Engineers (at the Central Hall, Westminster, London, S.W.1), at 6 p m.—Mr. L. J. Davies : "Transistors and All That" (Faraday Lecture).

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. G. E. Bessey : "An Investigation of the Properties of Mortars".

Plastics Institute (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Prof. G. Gee, F.R.S. Swinburne Award Address.

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Symposium on "Fungus Diseases". Contributors Prof. W. St. C. Symmers, Dr. Ian Murray and Dr. Mary Marples.

British Institute of Radiology (at 32 Welbeck Street, London, W.1), at 8 p.m.—Mr B. B. Milstein, Mr. D. A. W. Edwards, and Mr. F. R. Berridge : "The Mechanism of the Cardia".

Friday, February 17

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Symposium on "The Admiralty Chart", introduced by the Hydrographer of the Navy.

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. W. B. Thompson : "A Comprehensive Introduction to Plasma Physics".

Royal Society of Medicine, Epidemiology and Preventive Medicine Section (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Discussion on "Study of Control Methods in Tuberculosis". Speakers . Dr. James Grant, Dr. E. L. Feinmann, and Dr. K. M. Martischnig.

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. T. A. Blanco White · "Patent Protection for Chemical Inventions".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—The Right Hon. The Lord Adrian of Cambridge, O.M., F.R.S. . "Dreaming".

Saturday, February 18

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p m.—Mr. E. Roc . "Journey to Jebel Al Akhdar (Arabia)".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned .

Assistant Lecturer (with a good honours degree in either botany or agricultural botany and a special interest in mycology or plant pathology) in the Department of Agricultural Botany—The Registrar, University College of Wales, Aberystwyth (February 18).

Senior Technician (with appropriate H.N.C. or C. and G. Final Certificate or equivalent) in the Physics Department, for servicing electronics equipment—The Registrar, Brighton Technical College, Richmond Terrace, Brighton, 7 (February 18).

Lecturer in Electric Traction in the Department of Electrical Engineering—Head of the Electrical Engineering Department, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (February 20).

Lecturer or Assistant Lecturer (with special qualifications in applied mathematics) ; and a Lecturer or Assistant Lecturer (with special qualifications in pure mathematics) in the Department of Mathematics of the Faculty of Science—The Registrar, The University, Manchester 13 (February 20).

Biochemist (honours graduate, with some research experience) to assist Dr. R. M. C. Dawson on isotopic studies on lipid metabolism in rumen micro-organisms and in the ruminant digestive tract—The Secretary, Institute of Animal Physiology, A.R.C., Babraham, Cambridge (February 23)

Senior Lecturer (with an honours degree in mathematics, and preferably a higher degree and some experience of research) in Applied Mathematics at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, February 25).

Assistant Lecturer (with a good honours degree and special interests in mineralogy) in Geology—The Registrar, King's College (University of London), Strand, London, W.C.2 (February 28).

Lecturer/Assistant Lecturer (preferably with experience in the field of gas discharge or solid state physics) in the Department of Physics—The Registrar, University College of North Staffordshire, Keele, Staffs. (February 28).

Lecturer (with a university degree in electrical engineering, subsequent experience in research, in teaching, or in industry, and a knowledge of the fundamentals of nuclear engineering) in Electrical Engineering at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (February 28).

Soil Survey Officer (male, with a first- or second-class honours degree in science) **for the Soil Survey of Scotland**—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (February 28).

Lecturer (with a special interest in geomorphology and/or economic geography) **in Geography**—The Secretary, The Queen's University, Belfast (March 1).

Senior Lecturer or **Lecturer in Physics** at the School of General Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, March 4).

Assistant Lecturer in Physical Chemistry—The Registrar, The University, Hull (March 6)

Lecturer and an **Assistant Lecturer** (men or women graduates) **in the Department of Zoology**—The Secretary to Council, Westfield College (University of London), Hampstead, London, N.W.3 (March 6).

Lecturer (with an honours degree in engineering or science with research and/or professional experience in one of the fields of radio communications, radio physics, or information theory) **in Electrical Engineering** at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, March 6).

Lecturer or **Assistant Lecturer** (with a special interest in plant physiology or biophysics) **in Botany**—The Registrar, University College, Singleton Park, Swansea (March 11).

Technical Officer (with a university degree in science or equivalent qualification and interested in the application and development of techniques for teaching and research in botany and/or biochemistry) **in the Department of Botany**, to be responsible for the general supervision and maintenance of the laboratories and the control and training of technical staff—The Registrar, University College, Singleton Park, Swansea (March 11).

Lecturer in Psychology at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, March 15).

Post-doctoral Research Fellow in Organic Chemistry for work which will involve a chemical study of the biosynthesis of pteridines, under the direction of Dr. H. C. S. Wood—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C.1 (March 15).

Professor of Pure Mathematics at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, March 20).

Senior Lecturer in Physics in the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, March 31).

Senior Lecturer in Medical Statistics in the Department of Public Health and Social Medicine—The Secretary, The University, Edinburgh (April 1).

Agricultural Chemist (with a good honours degree in agricultural chemistry or chemistry, and at least two years postgraduate research experience in agricultural chemistry) in Kenya, to take charge of research projects into soil and plant nutrition problems of coffee—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD. 63/7/050/C1.

Assistant Systematic Botanist (honours graduate in botany or agricultural botany)—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Editorial Assistant (with a university degree in science or technology, and preferably at least two years postgraduate experience in science or industry)—The Manager, *Nature* Office, Macmillan and Co., Ltd., St. Martin's Street, London, W.C.2.

Lecturer (preferably with a special interest in deformation and fracture, a knowledge of solid mechanics, and experience in some industrial field) **in Metallurgy in the Department of Materials**—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks.

Lecturer (with geochemical qualifications and familiar with one or more of the following techniques: optical or X-ray spectrography, silicate or radioactive analysis) **in Pure Geochemistry**—Prof. D. Williams, Department of Geology Imperial College of Science and Technology, London, S.W.7.

Master to teach Physics to AS level and some Mathematics to O level—The Headmaster, Westminster School, 17 Dean's Yard, London, S.W.1.

Master to teach Physics to AS level; Chemistry to O level; and, if possible, some junior Biology and Mathematics—The Headmaster, Bloxham School, Banbury, Oxon.

Research Assistant to help with current research on an immunological project connected with rheumatoid arthritis—The Pathologist, Stoke Mandeville Hospital, Aylesbury, Bucks.

Senior Lecturer (qualified to direct research) **in Physics**—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

REPORTS and other PUBLICATIONS

SELECTED PAPERS ON
STRESS ANALYSIS

Presented at the Institute of Physics
Stress Analysis Group Conference—Delft 1959

Altogether 51 papers were discussed at the conference. In this volume, 18 papers are printed in the forms in which they were presented and in their original languages, together with summaries in the three languages of the conference. An English résumé has been prepared of the remaining 33 papers. This is followed by a list of titles and authors with their addresses, so that further information on the topics covered by the résumé can be obtained from the authors. *Illustrated. 50s. net*

✱

A new Translation from the Russian

THE STRUCTURE OF GLASS
(Volume Two)

Proceedings of the Third All-Union Conference on the Glassy State,
Leningrad, November 1959

This volume presents a complete account of research work on the glassy state since the previous conference in 1953. The most modern optical, spectroscopic, and electrical techniques were used in studying the structure of glass in all its aspects, and the results are interpreted in the light of modern physical theories of the solid state. *Illustrated. 200s. net*

UNIVERSITY ADMINISTRATION IN GREAT BRITAIN

IN its recent policy statement "Science and Education"*, the Association of Scientific Workers suggested that there is to-day a lack of contact between the universities and the industrial and government research organizations, and that co-ordination of the scientific effort of the universities with that of government and industry is only likely to be achieved by resolute and vigorous action. Looking essentially to a Royal Commission as the best method of achieving this, the Association suggests further that the time is ripe for a searching examination of the value of the traditional methods of science teaching and research in the universities in the context of the present and future needs of Great Britain. Such an inquiry, moreover, might also consider ways of ameliorating the present intensive competitive specialization in sixth forms of schools resulting from the existing scholarship system.

The Association is fully aware that university expansion should be considered in relation to the expansion of technical education also, both of the technical schools and colleges and of the colleges of technology; and, specifically, it recommends the elaboration of a national plan for the co-ordinated development of universities, technical colleges, teacher-training colleges, agricultural colleges, and colleges of art and music in Britain. This is as far as the statement goes; it does not go into the question of university government and administration. This aspect was raised at the Conference of Universities of the United Kingdom in London last December, when there was some discussion, and also disagreement, about the relations of teaching and research. There was firm support, however, for full participation of the academic staff in governing university institutions, and the dangers of external influence were stressed rather to the extent of over-shadowing the importance of securing local support and understanding and of the value of the independent advice and experience which could be drawn from outside the academic world, on which Sir Arthur Rucker rightly laid stress in his recent report.

Some re-assurance on university autonomy, particularly in respect of the new institutions, was offered to the Conference by Viscount Mackintosh of Halifax, but this question of university administration has been brought forward in recent issues of *Science and Freedom*†. The question is clearly one which lies well within the terms of reference of the Robbins Committee, and it is essential that some clear and constructive thought should be given before the pattern of university expansion and the interrelations of university institutions with other institutions of higher education are determined. Indeed, such thinking may well be the essential condition of the continuance of academic autonomy in an age in which university institutions are increasingly dependent upon public finance.

Some four years ago, in an article entitled "Self-Government in Modern British Universities", Sir Eric Ashby suggested that it is essential for academic freedom in a university that the academic staff should have *de facto* control of the admission and examination of students; the curricula for courses of study; the appointment and tenure of office of academic staff; and the allocation of income among the different categories of expenditure. The last-named, however, constitutes the real difficulty, and Sir Eric, who recognized freely the important part that laymen on university councils have taken in defending academic freedom, pointed out that, in speaking of the responsibility of the university council for the wider interests of the university in the community, he does not mean the interests of the community in the university. Furthermore, academic freedom depends less on the formal constitution than on the spirit in which it is interpreted in practice by the governing body, in collaboration with the academic staff.

These points, and the further one that the main direction of flow of new ideas and proposals, in contrast with the flow of finance, is from below upwards and not in the reverse direction, are to be remembered in considering the controversy that has been provoked by Dr. A. P. Rowe's broadcast and his paper in *Science and Freedom*, entitled "The Problem of Freedom and Efficiency in Universities", on which that broadcast was largely based. Equally they have reference to the discussion on the place of the independent research institution arising out of an earlier broadcast talk by Prof. A. H. Cottrell, entitled, "Scientists: Solo or Concerted", which was published in *The Listener* of September 15.

Particularly in his broadcast talk, Dr. Rowe challenged the existing pattern of research and teaching in British universities, and the appropriateness of some of the arrangements made in the past for much smaller numbers of students, for the conditions of to-day when the numbers of students are not only much larger but also there are liable to be fewer students with first-class minds or from homes with a tradition of learning or culture. Supporting Baroness Wootton's suggestion in the House of Lords debate on May 11 that some inquiry should be made into the distribution of teaching and research among the staffs and faculties in different universities, he urged further that university research should be located primarily in institutes associated with universities and not in self-contained university departments. In addition, he suggested that more attention should be given both to the quality of university teaching and to the needs and treatment of the ordinary student.

---

* Science and Education: a Policy Statement by the Association of Scientific Workers. Pp. 16. (London: Association of Scientific Workers, 1960.) 1*s*.

† Committee on Science and Freedom. Bulletin No. 16: Freedom and Efficiency: Problems of University Administration in Britain and the Commonwealth. Pp. 32. (Manchester: Committee on Science and Freedom, 818 Wilmslow Road, 1960.)

It is from a re-assessment of the tasks of universities in Britain along such lines that Dr. Rowe proceeded to discuss the administration of a university. He visualizes a university organized flexibly, with interchangeable staffs and common social, library and other facilities, to undertake the three tasks, first, of teaching a majority of earnest, intelligent but not brilliant students, mostly from homes with little tradition of learning; secondly, of dealing with more senior students, capable of standing on their own feet and benefiting from contact with great minds, and who need advanced courses and training in research methods; and thirdly, with research, calling for continuity of effort and team-work. To achieve these ends, Dr. Rowe calls for the elimination of departmentalism and for a real measure of authority above the professorial level. This he would place in the hands of a very few able and experienced academic men with few other duties and appointed for a long period.

There is considerable foundation and support for the strongly held belief in the interdependence of research and teaching, but it will be remembered that the balance between teaching and research was one of the questions which Lord Simon of Wythenshawe suggested for inquiry by a Royal Commission or special committee. Whether it will be examined by the Robbins Committee remains to be seen, but Dr. Rowe has the support of Lord Beveridge and others in suggesting that more attention needs to be given to teaching. Nothing but good could come from any steps taken to emphasize the teaching functions of the university and to raise the standard of teaching, either by the revision of courses, the introduction of new methods, or by supervision of untrained and inexperienced teachers.

Nevertheless, Dr. Rowe has pointed out a number of weaknesses, which require administrative action for the most part if they are to be corrected, whether or not a change in the administrative structure of the universities is involved. A system which ensured that teaching ability drew its recognition and reward, as well as distinction in research, would of itself assist in putting university teaching back into its proper place; but Dr. Rowe merely distinguishes between learning and teaching, and on this point the analysis should go deeper. In intellectual work, both in the communication of knowledge and in the discovery of new knowledge, it is quality that counts; and in the expansion of university education, too great care cannot be taken to safeguard the pursuit of excellence. The outstanding danger is that of mediocrity. Great thinkers and scholars bring inspiration and stimulus not merely to the little cluster of research workers immediately around them, but also to successive generations of students in the whole university.

What seems clear enough is that some investigation of the quality of the research work being done in university laboratories, particularly with reference to the resources available and in comparison with that being done in the research institutes, of both independent foundations and of the Department of Scientific and Industrial Research, might well be worth while. Similarly, it would seem that teaching methods and courses should be re-examined in the light of the increasing numbers of university students of moderate ability with little tradition of learning. The second inquiry might appropriately be made by the individual universities, and the problem appears to be well to the front in the thinking of those responsible for the organization of the new universities in Britain. The first, however, calls for wider and independent examination, such as might, for example, be appropriately initiated by the Minister for Science or his Advisory Council for Scientific Policy. It obviously lies rather outside the scope of the Robbins Committee, though inquiry might well lead to findings with important administrative implications—as indeed is foreshadowed in the last report of the Advisory Council on Scientific Policy. Moreover, Prof. Cottrell has pointed out that the problems of administration of the research institute are very similar, and the implications are important if waste of national resources is to be avoided.

Despite, however, the approval given by Sir Arthur Rucker in his recent report to certain aspects of university administration, there appears to be a *prima facie* case for an independent examination of the whole structure of university administration in the light of the needs of to-day. Apart from the internal stresses that arise inevitably out of the sheer numerical size of expanding universities, the problems of adjusting the claims of teaching and research, those of research between the different disciplines and fields of knowledge, and particularly the relation between available national resources and what is being done elsewhere, either in other universities or in government or independent research institutions, are growing in complexity. It is already clear that more attention will have to be given to university co-operation, and increasingly the demands of university administration call for the separation of policy and executive management. This is not to suggest that a solution is to be found by imparting unmodified the type of organization which characterizes large, efficient and progressive business organizations. It is perhaps worth noting that the Committee under the chairmanship of Sir David Hughes Parry which reported a year ago on the New Zealand Universities (see *Nature*, 187, 107; 1960), besides recommending the establishment of a university grants committee, suggested governing bodies for the new universities of not more than twenty, including eight lay members, four of high standing in the Dominions and nominated by the Governor-General, and four co-opted by the governing body itself from those interested in the work and progress of the university and likely to give weight and authority to the university in the community. While the governing body has the final decision, it has full powers of delegation; further, the rights of the professorial board to be consulted on and to discuss any matter relating to the university, as well as its duty to advise the governing body, are emphasized. The Ashby Commission on Post-School Certificate and Higher Education in Nigeria takes a very similar line; its chapter in university government recommends a national universities commission, similar to the University Grants Committee in Britain, and emphasizes the importance of both the academic representation and the lay element on the governing bodies of Nigerian universities, as well as insisting on the undisputed autonomy of these governing bodies.

The whole subject deserves some careful and perhaps independent study and hard and creative thought. Universities, and the nation, might well benefit if a few university administrators found their way to the Administrative Staff College, though little might result unless the organization of their universities enabled them to give effect to measures which would eliminate waste and result in more effective use of highly trained staff; initially such measures usually tend to involve additional expenditure on technicians or auxiliary staff or equipment, and such expenditure, even if comparatively trivial, is not always readily sanctioned under existing arrangements as the University Grants Committee well knows. Lord Simon of Wythenshawe, to whose original suggestion of a Royal Commission the appointment of the Robbins Committee was ultimately due, had such administrative matters clearly in his mind, though he referred more specifically to the need for some means of co-ordinating the work of universities and that of other institutions for higher education. Even if the Robbins Committee does not itself look at these problems of the government and administration of universities in some detail, its report should leave no room for doubt as to the importance of such a full inquiry, or where the responsibility for initiating, as a matter of urgency, such an investigation most appropriately rests.

EVOLUTION OF THE FLOWER

Die Evolution der Angiospermen

Von Prof. Dr. Armen Takhtajan. Pp. viii+334. (Jena: Gustav Fischer Verlag, 1959.) 44.90 D.M.

THIS is a comprehensive work in German dealing with the flowering plants as a whole as well as in detail. The author is a Russian—strictly speaking an Armenian—and yet can write lucidly in languages other than his own. I have had letters from him in quite good English, making one blush at one's feeble attempts to communicate in any other language than one's own.

The opening sections deal with matters applicable generally to phylogeny—such as progressive, adaptive evolution and specialization. Here he uses a term new to me—'heterobathmie'. It means that one set of organs may advance while others remain static or even degenerate. This in a way may be considered axiomatic, but is not always taken into account in discussing phylogenies.

Some stress is also laid on 'neoteny' (pp. 25 and 143)—a somewhat new term as applied to botany, though it has been in use for some time in zoology—meaning the possibility of evolution advancing from juvenile stages with the elimination of the adult ones. Takhtajan thinks neoteny might help in explaining the very compressed type of gametophyte to be found in the angiospermous embryo sac. He has elaborated the idea of neoteny in essays of a somewhat philosophical nature recently translated from Russian and published in English. Perhaps he is inclined to overstress neoteny, but to make any new view impressive and to invite criticism an overstatement is not without its advantages.

After the general section, the work proceeds to discuss individually the various parts of the angiospermous plant from the evolutionary point of view. Sections are devoted to stem, leaf, conducting systems, flower, inflorescence, pollination, anther, embryo sac, male and female gametophytes, seed, fruit and aril. He enters into great detail regarding the structure of the pollen grain and its value in phylogeny.

Though a believer in the woody angiosperm preceding the herbaceous, he has a section on the passage back of the herb to the shrub. He points out that this would seem to have occurred in the five families which he mentions (p. 38). In all such cases it is necessary to emphasize that the reversion should be revealed structurally, particularly in the vascular elements. Evolution does not revert backwards morphologically, but does at times physiologically, that is, functionally. Hutchinson's second edition of his *Families of Flowering Plants* had only just appeared and apparently was not in time for Prof. Takhtajan to comment on the former's rigid division of the Dicotyledons into two main lines of woody and herbaceous forms. These he keeps as separate evolutions from non-existing ancestors, and, now in his second edition, is bold enough to name the Lignosae and Herbaceae respectively. It would be going outside the limits of this review to comment further on this far-reaching division of the Dicotyledons, but it is a matter that the systematists will have to take seriously into account.

The third part of the work is systematic, taking the orders in succession with descriptions of each, and appending to them the families they each include. The author further groups the orders into a higher category termed 'Überordnung'.

A few points in the scheme of classification, which is largely based on those of Bessey, Hallier and Hutchinson, may be mentioned. The genus *Paeonia* is now generally recognized to be worthy of a family to itself, Paeoniaceae. Hutchinson keeps it in the order Ranales; but Takhtajan widens the gap, as it were, placing it in the order Dilleniales. *Nelumbo*, the lotus lily, is removed from the Nymphaeales and given an order to itself, the Nelumbonales. One distinction from the other water lilies is shown in the structure of its pollen grain. The willows and poplars, the Salicaceae, always difficult to place, Takhtajan has put near the tamarisks and daphnes. Hutchinson still keeps them near the catkin families.

The author appends to the systematic descriptions a linear list of orders and families. On running through this list one is drawn up sharply with such unfamiliar names as Brassicaceae, Fabaceae, Apiaceae, Lamiaceae, Asteraceae, Poaceae, and Araceae in place of such time-honoured ones as Cruciferae, Papilionaceae, Umbelliferae, Labiatae, Compositae, Gramineae, and Palmae. One can see the reason for this. The old familiar names, except one, do not end in the customary '-aceae'. Without doing away with the old names entirely, could not each be extended by the interpolation of 'Ac', thus making them all end in '-aceae'? It is now generally admitted that the old Leguminosae is better split into three separate families. Hutchinson has the three now grouped under the order Leguminales, but Takhtajan under Fabiales. Would not the former be better, thus preserving the old name legume, so long associated with this group of plants?

It seems to me that some uniformity should be adopted regarding the above families. This might be settled at the next International Botanical Congress; and I would suggest that if a committee be formed for discussing nomenclature the horticulturist should be consulted as well as the systematist.

A word of appreciation must be said for the very full bibliography given. This alone makes the volume very desirable. There are also three quite useful indexes. In fact the text is so well documented that a work of this character in English would make a desirable advanced text-book for students.

The author is cautious in not putting forward any new speculations as to the solution of the still great problem, the origin of the Angiosperms. Reading between the lines and from correspondence, his inclination is towards the Magnolian–Bennittalean view as to the primitive features of the flower. Engler's main classification and the Caytonialian speculations are scarcely mentioned, looking as if they were now outmoded. J. PARKIN

HISTORY OF WESTERN IDEAS

The Western Intellectual Tradition from Leonardo to Hegel

By Dr. J. Bronowski and Dr. Bruce Mazlish. Pp. xviii + 522. (London: Hutchinson and Co. (Publishers), Ltd., 1960.) 30*s*. net.

THE authors set out to expound the history of Western thought from the late-fifteenth to the early-nineteenth centuries on three principles which, they claim, are fundamentally new. One is comprehensiveness—"we are interested in the whole spectrum of the mind"; the second is that ideas should be related to events; the third is that ideas should be studied through the men who first conceived them. The combination of these three principles, which they call triangulation, is intended to produce the "integration of intellectual history" and so make a coherent relationship between science and the humanities. They lay high claim to originality in so doing, and their preface is unusually full of self-congratulation for being pioneers in such a task.

The result, in view of these claims, is nevertheless conventional. They do not, fortunately, attempt to cover "the whole spectrum of the mind", for they say little about theology, moral philosophy, æsthetics, literature and drama, the fine arts, or indeed any realm of thought other than the conventional realms of political, social, economic and scientific thought. Their other two 'principles' are certainly not original, and they adopt the episodic chronological method already only too common in histories of political thought: some biographical facts, summaries of a man's ideas in relation to his life and times, some generalizations about his importance, above all for our own day. Their prime aim, to integrate scientific thought with social and political thought, cannot be achieved by merely including a chapter on the scientific revolution alongside those on Leonardo and Machiavelli, or one on the Royal Society along with those on Hobbes, Locke and Descartes. Nor have the historians of ideas, of whom they speak so contemptuously, been so unaware of the influence of a Galileo, a Newton, or a Watt. The remark of Sir Charles Snow which they quote with such warm approval can scarcely go on record as one of his more felicitous or accurate statements: "The steam engine helped to shape the modern world at least as much as Napoleon and Adam Smith, *but only rarely do the historians admit the fact*". The book ends, moreover, around 1830, just when the authors' self-imposed task would become really important but also extremely difficult.
